|----------------------|------------------|
| (UInt(immh:immb)-8) | when immh = 0001 |
| (UInt(immh:immb)-16) | when immh = 001x |
| (UInt(immh:immb)-32) | when immh = 01xx |
| (UInt(immh:immb)-64) | when immh = 1xxx |
- The encoding immh = 0000 is reserved.
- For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:
- | | |
|----------------------|------------------|
| (UInt(immh:immb)-8) | when immh = 0001 |
| (UInt(immh:immb)-16) | when immh = 001x |
| (UInt(immh:immb)-32) | when immh = 01xx |
| (UInt(immh:immb)-64) | when immh = 1xxx |

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elm[operand, e, esize], src_unsigned) << shift;
    (Elm[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

C7.2.259 SQSHRN, SQSHRN2

Signed saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see [SQRSHRN](#), [SQRSHRN2](#).

The SQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SQSHRN <Vb><d>, <Va><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then ReservedValue();
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = esize;
integer elements = 1;
integer part = 0;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

Vector

Vector variant

SQSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
```

```
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
 [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
 16B when immh = 0001, Q = 1
 4H when immh = 001x, Q = 0
 8H when immh = 001x, Q = 1
 2S when immh = 01xx, Q = 0
 4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
 4S when immh = 001x
 2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
 H when immh = 001x
 S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
 S when immh = 001x
 D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.260 SQSHRUN, SQSHRUN2

Signed saturating Shift Right Unsigned Narrow (immediate). This instruction reads each signed integer value in the vector of the source SIMD&FP register, right shifts each value by an immediate value, saturates the result to an unsigned integer value that is half the original width, places the final result into a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see [SQRSHRUN](#), [SQRSHRUN2](#).

The SQSHRUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQSHRUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
```

```
integer elements = datasize DIV esize;  
  
integer shift = (2 * esize) - UInt(immh:immb);  
boolean round = (op == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (SInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    (Elem[result, e, esize], sat) = UnsignedSatQ(element, esize);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.261 SQSUB

Signed saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SQSUB <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

Vector

Vector variant

SQSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

| | |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |

- D when size = 11
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 - 2D when size = 11, Q = 1
- The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    diff = element1 - element2;
    (Elem[result, e, esize], sat) = SatQ(diff, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

C7.2.262 SQXTN, SQXTN2

Signed saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SQXTN <Vb><d>, <Va><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer part = 0;
integer elements = 1;

boolean unsigned = (U == '1');
```

Vector

Vector variant

SQXTN{2} <Vd>.<Tb>, <Vn>.<Ta>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
```

integer elements = datasize DIV esize;

boolean unsigned = (U == '1');

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vb> Is the destination width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

H when size = 01

S when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Va> Is the source width specifier, encoded in the "size" field. It can have the following values:

H when size = 00

S when size = 01

D when size = 10

The encoding size = 11 is reserved.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;
```

```
for e = 0 to elements-1
  element = Elem[operand, e, 2*esize];
  (Elem[result, e, esize], sat) = SatQ(Int(element, unsigned), esize, unsigned);
  if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.263 SQXTUN, SQXTUN2

Signed saturating extract Unsigned Narrow. This instruction reads each signed integer value in the vector of the source SIMD&FP register, saturates the value to an unsigned integer value that is half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The SQXTUN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SQXTUN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

- <n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;

for e = 0 to elements-1
    element = Elem[operand, e, 2*esize];
    (Elem[result, e, esize], sat) = UnsignedSatQ(SInt(element), esize);
```

```
if sat then FPSR.QC = '1';  
Vpart[d, part] = result;
```

C7.2.264 SRHADD

Signed Rounding Halving Add. This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see [SHADD](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

SRHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
```

C7.2.265 SRI

Shift Right and Insert (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

The following figure shows an example of the operation of shift right by 3 for an 8-bit vector element.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SRI <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immb);
```

Vector

Vector variant

SRI <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immb);
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- D when immh = 1xxx
- The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 8B when immh = 0001, Q = 0
 - 16B when immh = 0001, Q = 1
 - 4H when immh = 001x, Q = 0
 - 8H when immh = 001x, Q = 1
 - 2S when immh = 01xx, Q = 0
 - 4S when immh = 01xx, Q = 1
 - 2D when immh = 1xxx, Q = 1
- See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.
- The encoding immh = 1xxx, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
- (128-UInt(immh:immb)) when immh = 1xxx
- The encoding immh = 0xxx is reserved.
- For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
- (16-UInt(immh:immb)) when immh = 0001
 - (32-UInt(immh:immb)) when immh = 001x
 - (64-UInt(immh:immb)) when immh = 01xx
 - (128-UInt(immh:immb)) when immh = 1xxx
- See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2 = V[d];
bits(datasize) result;
```

```
bits(size) mask = LSR(Ones(size), shift);
bits(size) shifted;

for e = 0 to elements-1
    shifted = LSR(Elem[operand, e, esize], shift);
    Elem[result, e, esize] = (Elem[operand2, e, esize] AND NOT(mask)) OR shifted;
V[d] = result;
```

C7.2.266 SRSHL

Signed Rounding Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see [SSHL](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SRSHL <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

Vector

Vector variant

SRSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
    
```

C7.2.269 SSHL

Signed Shift Left (register). This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see [SRSHL](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SSHL <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

Vector

Vector variant

SSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "size" field. It can have the following values:
 D when size = 11
 The following encodings are reserved:
- size = 0x.
 - size = 10.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 8B when size = 00, Q = 0
 16B when size = 00, Q = 1
 4H when size = 01, Q = 0
 8H when size = 01, Q = 1
 2S when size = 10, Q = 0
 4S when size = 10, Q = 1
 2D when size = 11, Q = 1
 The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
  shift = SInt(ELem[operand2, e, esize]<7:0>);
  if rounding then
    round_const = 1 << (-shift - 1); // 0 for left shift, 2^(n-1) for right shift
  element = (Int(ELem[operand1, e, esize], unsigned) + round_const) << shift;
  if saturating then
    (ELem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';
  else
    ELem[result, e, esize] = element<esize-1:0>;

V[d] = result;
  
```

C7.2.270 SSHLL, SSHLL2

Signed Shift Left Long (immediate). This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SSHLL instruction extracts vector elements from the lower half of the source register, while the SSHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2. See *Alias conditions* for details of when each alias is preferred.

Vector variant

SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

| Alias | is preferred when |
|-------------|--------------------------------------|
| SXTL, SXTL2 | immb == '000' && BitCount(immh) == 1 |

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
 - 8H when immh = 0001
 - 4S when immh = 001x

2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

C7.2.271 SSHR

Signed Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, places the final result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see [SRSHR](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SSHR <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector

Vector variant

SSHR <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
D when immh = 1xxx
The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1
2D when immh = 1xxx, Q = 1
See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.
The encoding immh = 1xxx, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
(128-UInt(immh:immb)) when immh = 1xxx
The encoding immh = 0xxx is reserved.
For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
(16-UInt(immh:immb)) when immh = 0001
(32-UInt(immh:immb)) when immh = 001x
(64-UInt(immh:immb)) when immh = 01xx
(128-UInt(immh:immb)) when immh = 1xxx
See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
```

C7.2.272 SSRA

Signed Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are signed integer values. The results are truncated. For rounded results, see [SRSRA](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SSRA <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector

Vector variant

SSRA <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
 D when immh = 1xxx
 The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
    
```

C7.2.273 SSUBL, SSUBL2

Signed Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The SSUBL instruction extracts each source vector from the lower half of each source register, while the SSUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SSUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.274 SSUBW, SSUBW2

Signed Subtract Wide. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The SSUBW instruction extracts the second source vector from the lower half of the second source register, while the SSUBW2 instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SSUBW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |

The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.275 ST1 (multiple structures)

Store multiple single-element structures from one, two, three, or four registers. This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

One register variant

Applies when opcode == 0111.

ST1 { <Vt>.<T> }, [<Xn|SP>]

Two registers variant

Applies when opcode == 1010.

ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

Three registers variant

Applies when opcode == 0110.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]

Four registers variant

Applies when opcode == 0010.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index

One register, immediate offset variant

Applies when Rm == 11111 && opcode == 0111.

ST1 { <Vt>.<T> }, [<Xn|SP>], <imm>

One register, register offset variant

Applies when Rm != 11111 && opcode == 0111.

ST1 { <Vt>.<T> }, [<Xn|SP>], <Xm>

Two registers, immediate offset variant

Applies when Rm == 11111 && opcode == 1010.

ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>

Two registers, register offset variant

Applies when Rm != 11111 && opcode == 1010.

ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

Three registers, immediate offset variant

Applies when Rm == 11111 && opcode == 0110.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>

Three registers, register offset variant

Applies when Rm != 11111 && opcode == 0110.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>

Four registers, immediate offset variant

Applies when Rm == 11111 && opcode == 0010.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>

Four registers, register offset variant

Applies when Rm != 11111 && opcode == 0010.

ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 1D when size = 11, Q = 0
- 2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.

- <Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 #8 when Q = 0
 #16 when Q = 1
 For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 #16 when Q = 0
 #32 when Q = 1
 For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 #24 when Q = 0
 #48 when Q = 1
 For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 #32 when Q = 0
 #64 when Q = 1
- <Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;

integer rpt; // number of iterations
integer selem; // structure elements

case opcode of
  when '0000' rpt = 1; selem = 4; // LD/ST4 (4 registers)
  when '0010' rpt = 4; selem = 1; // LD/ST1 (4 registers)
  when '0100' rpt = 1; selem = 3; // LD/ST3 (3 registers)
  when '0110' rpt = 3; selem = 1; // LD/ST1 (3 registers)
  when '0111' rpt = 1; selem = 1; // LD/ST1 (1 register)
  when '1000' rpt = 1; selem = 2; // LD/ST2 (2 registers)
  when '1010' rpt = 2; selem = 1; // LD/ST1 (2 registers)
  otherwise UnallocatedEncoding();

// .1D format only permitted with LD1 & ST1
if size:Q == '110' && selem != 1 then ReservedValue();
```

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(64) offs;
bits(datasize) rval;
integer e, r, s, tt;
constant integer ebytes = esize DIV 8;

if n == 31 then
  CheckSPAlignment();
  address = SP[];
```

```
else
    address = X[n];

offs = Zeros();
for r = 0 to rpt-1

        tt = (t + r) MOD 32;
        for s = 0 to selem-1
            rval = V[tt];
            if memop == MemOp_LOAD then
                Elem[rval, e, esize] = Mem[address+offs, ebytes, AccType_VEC];
                V[tt] = rval;
            else // memop == MemOp_STORE
                Mem[address+offs, ebytes, AccType_VEC] = Elem[rval, e, esize];
            offs = offs + ebytes;
            tt = (tt + 1) MOD 32;

if wback then
    if m != 31 then
        offs = X[m];
    if n == 31 then
        SP[] = address + offs;
    else
        X[n] = address + offs;
```

C7.2.276 ST1 (single structure)

Store a single-element structure from one lane of one register. This instruction stores the specified element of a SIMD&FP register to memory.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

8-bit variant

Applies when opcode == 000.

ST1 { <Vt>.B }[<index>], [<Xn|SP>]

16-bit variant

Applies when opcode == 010 && size == x0.

ST1 { <Vt>.H }[<index>], [<Xn|SP>]

32-bit variant

Applies when opcode == 100 && size == 00.

ST1 { <Vt>.S }[<index>], [<Xn|SP>]

64-bit variant

Applies when opcode == 100 && S == 0 && size == 01.

ST1 { <Vt>.D }[<index>], [<Xn|SP>]

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index

8-bit, immediate offset variant

Applies when Rm == 11111 && opcode == 000.

ST1 { <Vt>.B }[<index>], [<Xn|SP>], #1

8-bit, register offset variant

Applies when Rm != 11111 && opcode == 000.

ST1 { <Vt>.B }[<index>], [<Xn|SP>], <Xm>

16-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 010$ && $size == x0$.

ST1 { <Vt>.H }[<index>], [<Xn|SP>], #2

16-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 010$ && $size == x0$.

ST1 { <Vt>.H }[<index>], [<Xn|SP>], <Xm>

32-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 100$ && $size == 00$.

ST1 { <Vt>.S }[<index>], [<Xn|SP>], #4

32-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 100$ && $size == 00$.

ST1 { <Vt>.S }[<index>], [<Xn|SP>], <Xm>

64-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 100$ && $S == 0$ && $size == 01$.

ST1 { <Vt>.D }[<index>], [<Xn|SP>], #8

64-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 100$ && $S == 0$ && $size == 01$.

ST1 { <Vt>.D }[<index>], [<Xn|SP>], <Xm>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

| | |
|---------|--|
| <Vt> | Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field. |

C7.2.277 ST2 (multiple structures)

Store multiple 2-element structures from two registers. This instruction stores multiple 2-element structures from two SIMD&FP registers to memory, with interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

No offset variant

ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

Decode for this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index

Immediate offset variant

Applies when Rm == 11111.

ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>

Register offset variant

Applies when Rm != 11111.

ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

- <Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

| | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |

2S when size = 10, Q = 0
 4S when size = 10, Q = 1
 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
 <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
 <imm> Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 #16 when Q = 0
 #32 when Q = 1
 <Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```

C7.2.281 ST4 (multiple structures)

Store multiple 4-element structures from four registers. This instruction stores multiple 4-element structures to memory from four SIMD&FP registers, with interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

No offset variant

ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]

Decode for this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index

Immediate offset variant

Applies when Rm == 11111.

ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>

Register offset variant

Applies when Rm != 11111.

ST4 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

- <Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the "Rt" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1

2S when size = 10, Q = 0
 4S when size = 10, Q = 1
 2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

- <Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as "Rt" plus 1 modulo 32.
- <Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as "Rt" plus 2 modulo 32.
- <Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as "Rt" plus 3 modulo 32.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <imm> Is the post-index immediate offset, encoded in the "Q" field. It can have the following values:
 - #32 when Q = 0
 - #64 when Q = 1
- <Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the "Rm" field.

Shared decode for all encodings

```

C7.2.282 ST4 (single structure)

Store single 4-element structure from one lane of four registers. This instruction stores a 4-element structure to memory from corresponding elements of four SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

No offset

8-bit variant

Applies when opcode == 001.

ST4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>]

16-bit variant

Applies when opcode == 011 && size == x0.

ST4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>]

32-bit variant

Applies when opcode == 101 && size == 00.

ST4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>]

64-bit variant

Applies when opcode == 101 && S == 0 && size == 01.

ST4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>]

Decode for all variants of this encoding

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index

8-bit, immediate offset variant

Applies when Rm == 11111 && opcode == 001.

ST4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], #4

8-bit, register offset variant

Applies when Rm != 11111 && opcode == 001.

ST4 { <Vt>.B, <Vt2>.B, <Vt3>.B, <Vt4>.B }[<index>], [<Xn|SP>], <Xm>

16-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 011$ && $size == x0$.

ST4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>], #8

16-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 011$ && $size == x0$.

ST4 { <Vt>.H, <Vt2>.H, <Vt3>.H, <Vt4>.H }[<index>], [<Xn|SP>], <Xm>

32-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 101$ && $size == 00$.

ST4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>], #16

32-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 101$ && $size == 00$.

ST4 { <Vt>.S, <Vt2>.S, <Vt3>.S, <Vt4>.S }[<index>], [<Xn|SP>], <Xm>

64-bit, immediate offset variant

Applies when $Rm == 11111$ && $opcode == 101$ && $S == 0$ && $size == 01$.

ST4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>], #32

64-bit, register offset variant

Applies when $Rm != 11111$ && $opcode == 101$ && $S == 0$ && $size == 01$.

ST4 { <Vt>.D, <Vt2>.D, <Vt3>.D, <Vt4>.D }[<index>], [<Xn|SP>], <Xm>

Decode for all variants of this encoding

```
integer t = UInt(Rt);

```

C7.2.283 STNP (SIMD&FP)

Store Pair of SIMD&FP registers, with Non-temporal hint. This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see [Load/Store SIMD and Floating-point Non-temporal pair on page C3-154](#).

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

32-bit variant

Applies when `opc == 00`.

STNP <St1>, <St2>, [<Xn|SP>{, #<imm>}]

64-bit variant

Applies when `opc == 01`.

STNP <Dt1>, <Dt2>, [<Xn|SP>{, #<imm>}]

128-bit variant

Applies when `opc == 10`.

STNP <Qt1>, <Qt2>, [<Xn|SP>{, #<imm>}]

Decode for all variants of this encoding

// Empty.

Assembler symbols

- <Dt1> Is the 64-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- <Dt2> Is the 64-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.
- <Qt1> Is the 128-bit name of the first SIMD&FP register to be transferred, encoded in the "Rt" field.
- <Qt2> Is the 128-bit name of the second SIMD&FP register to be transferred, encoded in the "Rt2" field.

C7.2.286 STR (register, SIMD&FP)

Store SIMD&FP register (register offset). This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an offset register value. The offset can be optionally shifted and extended.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

8-bit variant

Applies when size == 00 && opc == 00 && option != 011.

```

C7.2.288 SUB (vector)

Subtract (vector). This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SUB <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

Vector

Vector variant

SUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

D when size = 11

The following encodings are reserved:

- size = 0x.
- size = 10.

- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
| 2D | when size = 11, Q = 1 |
- The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;
```

C7.2.289 SUBHN, SUBHN2

Subtract returning High Narrow. This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see [RSUBHN](#), [RSUBHN2](#).

The SUBHN instruction writes the vector to the lower half of the destination register and clears the upper half, while the SUBHN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

SUBHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01

2D when size = 10

The encoding size = 11 is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize) result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

C7.2.290 SUQADD

Signed saturating Accumulate of Unsigned value. This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

SUQADD <V><d>, <V><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean unsigned = (U == '1');
```

Vector

Vector variant

SUQADD <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

| | |
|---|----------------|
| B | when size = 00 |
|---|----------------|

- H when size = 01
S when size = 10
D when size = 11
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.2.291 SXTL, SXTL2

Signed extend Long. This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The SXTL instruction extracts the source vector from the lower half of the source register, while the SXTL2 instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the SSHLL, SSHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode for this instruction.

Vector variant

SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

Operation

The description of [SSHLL](#), [SSHLL2](#) gives the operational pseudocode for this instruction.

C7.2.292 TBL

Table vector Lookup. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant

Applies when len == 01.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant

Applies when len == 10.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant

Applies when len == 11.

TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant

Applies when len == 00.

TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
 - 8B when Q = 0
 - 16B when Q = 1
- <Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.

For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.

- <Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.
- <Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.
- <Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.
- <Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

C7.2.293 TBX

Table vector lookup extension. This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Two register table variant

Applies when len == 01.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>

Three register table variant

Applies when len == 10.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>

Four register table variant

Applies when len == 11.

TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>

Single register table variant

Applies when len == 00.

TBX <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "Q" field. It can have the following values:
 - 8B when Q = 0
 - 16B when Q = 1

- <Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the "Rn" field.
For the single register table variant: is the name of the SIMD&FP table register, encoded in the "Rn" field.
- <Vn+1> Is the name of the second SIMD&FP table register, encoded as "Rn" plus 1 modulo 32.
- <Vn+2> Is the name of the third SIMD&FP table register, encoded as "Rn" plus 2 modulo 32.
- <Vn+3> Is the name of the fourth SIMD&FP table register, encoded as "Rn" plus 3 modulo 32.
- <Vm> Is the name of the SIMD&FP index register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;

// Create table from registers
for i = 0 to regs-1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements-1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

C7.2.294 TRN1

Transpose vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

———— **Note** ————

By using this instruction with TRN2, a 2 x 2 matrix can be transposed.

The following figure shows an example of the operation of TRN1 and TRN2 halfword operations where Q = 0.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

TRN1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0

16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, 2*p+part, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, 2*p+part, esize];

V[d] = result;
```

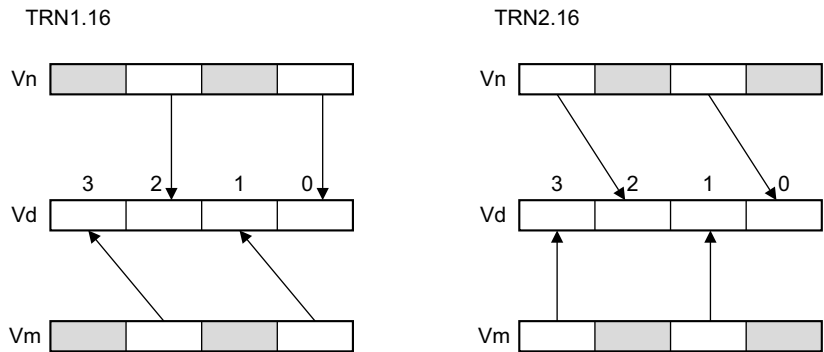

C7.2.295 TRN2

Transpose vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

———— **Note** ————

By using this instruction with TRN1, a 2 x 2 matrix can be transposed.

The following figure shows an example of the operation of TRN1 and TRN2 halfword operations where Q = 0.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

TRN2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0

16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();  
bits(datasize) operand1 = V[n];  
bits(datasize) operand2 = V[m];  
bits(datasize) result;  
integer p;  
  
for p = 0 to pairs-1  
    Elem[result, 2*p+0, esize] = Elem[operand1, 2*p+part, esize];  
    Elem[result, 2*p+1, esize] = Elem[operand2, 2*p+part, esize];  
  
V[d] = result;
```

C7.2.296 UABA

Unsigned Absolute difference and Accumulate. This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the elements of the vector of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UABA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();  
for e = 0 to elements-1  
    element1 = Int(Elem[operand1, e, esize], unsigned);  
    element2 = Int(Elem[operand2, e, esize], unsigned);  
    absdiff = Abs(element1-element2)<esize-1:0>;  
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;  
V[d] = result;
```

C7.2.297 UABAL, UABAL2

Unsigned Absolute difference and Accumulate Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UABAL instruction extracts each source vector from the lower half of each source register, while the UABAL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UABAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0

16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

C7.2.298 UABD

Unsigned Absolute Difference (vector). This instruction subtracts the elements of the vector of the second source SIMD&FP register from the corresponding elements of the first source SIMD&FP register, places the absolute values of the results into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean accumulate = (ac == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) absdiff;
```

```
result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<esize-1:0>;
    Elem[result, e, esize] = Elem[result, e, esize] + absdiff;
V[d] = result;
```

C7.2.299 UABDL, UABDL2

Unsigned Absolute Difference Long. This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, places the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UABDL instruction extracts each source vector from the lower half of each source register, while the UABDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UABDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean accumulate = (op == '0');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0

16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) absdiff;

result = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    absdiff = Abs(element1-element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + absdiff;
V[d] = result;
```

C7.2.300 UADALP

Unsigned Add and Accumulate Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UADALP <Vd>.<Ta>, <Vn>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 4H when size = 00, Q = 0
 - 8H when size = 00, Q = 1
 - 2S when size = 01, Q = 0
 - 4S when size = 01, Q = 1
 - 1D when size = 10, Q = 0
 - 2D when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

C7.2.301 UADDL, UADDL2

Unsigned Add Long (vector). This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The UADDL instruction extracts each source vector from the lower half of each source register, while the UADDL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UADDL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.302 UADDLP

Unsigned Add Long Pairwise. This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UADDLP <Vd>.<Ta>, <Vn>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV (2 * esize);
boolean acc = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 4H when size = 00, Q = 0
 - 8H when size = 00, Q = 1
 - 2S when size = 01, Q = 0
 - 4S when size = 01, Q = 1
 - 1D when size = 10, Q = 0
 - 2D when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(2*esize) sum;
integer op1;
integer op2;

result = if acc then V[d] else Zeros();
for e = 0 to elements-1
    op1 = Int(Elem[operand, 2*e+0, esize], unsigned);
    op2 = Int(Elem[operand, 2*e+1, esize], unsigned);
    sum = (op1+op2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = Elem[result, e, 2*esize] + sum;

V[d] = result;
```

C7.2.303 UADDLV

Unsigned sum Long across Vector. This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UADDLV <V><d>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is the destination width specifier, encoded in the "size" field. It can have the following values:

- H when size = 00
- S when size = 01
- D when size = 10

The encoding size = 11 is reserved.

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 4S when size = 10, Q = 1

The following encodings are reserved:

- size = 10, Q = 0.
- size = 11, Q = x.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer sum;

sum = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    sum = sum + Int(Elem[operand, e, esize], unsigned);

V[d] = sum<2*esize-1:0>;
```

C7.2.304 UADDW, UADDW2

Unsigned Add Wide. This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The UADDW instruction extracts vector elements from the lower half of the second source register, while the UADDW2 instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UADDW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.305 UCVTF (vector, fixed-point)

Unsigned fixed-point Convert to Floating-point (vector). This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the **FPCR**, and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in **FPCR**, the exception results in either a flag being set in **FPSR**, or a synchronous exception being generated. For more information, see [Floating-point exception traps on page D1-1552](#).

Depending on the settings in the **CPACR_EL1**, **CPTR_EL2**, and **CPTR_EL3** registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UCVTF <V><d>, <V><n>, #<fbits>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '00xx' then ReservedValue();
integer esize = 32 << UInt(immh<3>);
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

Vector

Vector variant

UCVTF <Vd>.<T>, <Vn>.<T>, #<fbits>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh == '00xx' then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
integer esize = 32 << UInt(immh<3>);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
- S when immh = 01xx
 - D when immh = 1xxx
- The encoding immh = 00xx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
- 2S when immh = 01xx, Q = 0
 - 4S when immh = 01xx, Q = 1
 - 2D when immh = 1xxx, Q = 1
- See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.
- The following encodings are reserved:
- immh = 0001, Q = x.
 - immh = 001x, Q = x.
 - immh = 1xxx, Q = 0.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the "immh:immb" field. It can have the following values:
- (64-UInt(immh:immb)) when immh = 01xx
 - (128-UInt(immh:immb)) when immh = 1xxx
- The encoding immh = 00xx is reserved.
- For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the "immh:immb" field. It can have the following values:
- (64-UInt(immh:immb)) when immh = 01xx
 - (128-UInt(immh:immb)) when immh = 1xxx
- See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.
- The following encodings are reserved:
- immh = 0001.
 - immh = 001x.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
  element = Elem[operand, e, esize];
```

```
Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);  
V[d] = result;
```

C7.2.306 UCVTF (vector, integer)

Unsigned integer Convert to Floating-point (vector). This instruction converts each element in a vector from an unsigned integer value to a floating-point value using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exception traps on page D1-1552](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UCVTF <V><d>, <V><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

Vector

Vector variant

UCVTF <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "sz" field. It can have the following values:

| | |
|---|-------------|
| S | when sz = 0 |
| D | when sz = 1 |

- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
- 2S when sz = 0, Q = 0
 - 4S when sz = 0, Q = 1
 - 2D when sz = 1, Q = 1
- The encoding sz = 1, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
FPRounding rounding = FPRoundingMode(FPCR);
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FixedToFP(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.2.307 UCVTF (scalar, fixed-point)

Unsigned fixed-point Convert to Floating-point (scalar). This instruction converts the unsigned value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exception traps on page D1-1552](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the Security state and Exception level in which the instruction is executed, an attempt to execute the instruction might be trapped.

32-bit to single-precision variant

Applies when `sf == 0 && type == 00`.

UCVTF <Sd>, <Wn>, #<fbits>

32-bit to double-precision variant

Applies when `sf == 0 && type == 01`.

UCVTF <Dd>, <Wn>, #<fbits>

64-bit to single-precision variant

Applies when `sf == 1 && type == 00`.

UCVTF <Sd>, <Xn>, #<fbits>

64-bit to double-precision variant

Applies when `sf == 1 && type == 01`.

UCVTF <Dd>, <Xn>, #<fbits>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;

case type of
    when '00' fltsize = 32;
    when '01' fltsize = 64;
    when '1x' UnallocatedEncoding();

if sf == '0' && scale<5> == '0' then UnallocatedEncoding();
integer fracbits = 64 - UInt(scale);

rounding = FPRoundingMode(FPCR);
```

Assembler symbols

| | |
|---------|--|
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field. |
| <Sd> | Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field. |
| <Xn> | Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field. |
| <Wn> | Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field. |
| <fbits> | For the 32-bit to double-precision and 32-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 32, encoded as 64 minus "scale". For the 64-bit to double-precision and 64-bit to single-precision variant: is the number of bits after the binary point in the fixed-point source, in the range 1 to 64, encoded as 64 minus "scale". |

Operation

```
CheckFPAdvSIMDEnabled64();  
  
bits(fltsize) fltval;  
bits(intsize) intval;  
  
intval = X[n];  
fltval = FixedToFP(intval, fracbits, TRUE, FPCR, rounding);  
V[d] = fltval;
```

C7.2.308 UCVTF (scalar, integer)

Unsigned integer Convert to Floating-point (scalar). This instruction converts the unsigned integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the [FPCR](#), and writes the result to the SIMD&FP destination register.

A floating-point exception can be generated by this instruction. Depending on the settings in [FPCR](#), the exception results in either a flag being set in [FPSR](#), or a synchronous exception being generated. For more information, see [Floating-point exception traps on page D1-1552](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

32-bit to single-precision variant

Applies when sf == 0 && type == 00.

UCVTF <Sd>, <Wn>

32-bit to double-precision variant

Applies when sf == 0 && type == 01.

UCVTF <Dd>, <Wn>

64-bit to single-precision variant

Applies when sf == 1 && type == 00.

UCVTF <Sd>, <Xn>

64-bit to double-precision variant

Applies when sf == 1 && type == 01.

UCVTF <Dd>, <Xn>

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPRounding rounding;

case type of
    when '00'
        fltsize = 32;
    when '01'
        fltsize = 64;
    when '10'
        UnallocatedEncoding();
    when '11'
        UnallocatedEncoding();

rounding = FPRoundingMode(FPCR);
```

Assembler symbols

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Xn> Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.
- <Wn> Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
```

```
bits(fltsize) fltval;  
bits(intsize) intval;
```

```
intval = X[n];  
fltval = FixedToFP(intval, 0, TRUE, FPCR, rounding);  
V[d] = fltval;
```

C7.2.309 UHADD

Unsigned Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see [URHADD](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;

V[d] = result;
```

C7.2.310 UHSUB

Unsigned Halving Subtract. This instruction subtracts the vector elements in the second source SIMD&FP register from the corresponding vector elements in the first source SIMD&FP register, shifts each result right one bit, places each result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
```

```
element2 = Int(Elem[operand2, e, esize], unsigned);  
diff = element1 - element2;  
Elem[result, e, esize] = diff<esize:1>;  
  
V[d] = result;
```

C7.2.311 UMAX

Unsigned Maximum (vector). This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UMAX <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

C7.2.312 UMAXP

Unsigned Maximum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UMAXP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

C7.2.313 UMAXV

Unsigned Maximum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UMAXV <V><d>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

Assembler symbols

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- | | |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |
- The encoding size = 11 is reserved.
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 4S | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
 - size = 11, Q = x.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<size-1:0>;
```

C7.2.314 UMIN

Unsigned Minimum (vector). This instruction compares corresponding vector elements in the two source SIMD&FP registers, places the smaller of each of the two unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UMIN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer maxmin;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);
    Elem[result, e, esize] = maxmin<esize-1:0>;

V[d] = result;
```

C7.2.315 UMINP

Unsigned Minimum Pairwise. This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

UMINP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

```
boolean unsigned = (U == '1');
boolean minimum = (o1 == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
integer element1;
integer element2;
```

```
integer maxmin;  
  
for e = 0 to elements-1  
    element1 = Int(Elem[concat, 2*e, esize], unsigned);  
    element2 = Int(Elem[concat, (2*e)+1, esize], unsigned);  
    maxmin = if minimum then Min(element1, element2) else Max(element1, element2);  
    Elem[result, e, esize] = maxmin<esize-1:0>;  
  
V[d] = result;
```

C7.2.316 UMINV

Unsigned Minimum across Vector. This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UMINV <V><d>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean min = (op == '1');
```

Assembler symbols

- <V> Is the destination width specifier, encoded in the "size" field. It can have the following values:
- | | |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |
- The encoding size = 11 is reserved.
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 4S | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 10, Q = 0.
 - size = 11, Q = x.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
integer maxmin;
integer element;

maxmin = Int(Elem[operand, 0, esize], unsigned);
for e = 1 to elements-1
    element = Int(Elem[operand, e, esize], unsigned);
    maxmin = if min then Min(maxmin, element) else Max(maxmin, element);

V[d] = maxmin<size-1:0>;
```

C7.2.317 UMLAL, UMLAL2 (by element)

Unsigned Multiply-Add Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
    
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- 4S when size = 01
 - 2D when size = 10
- The following encodings are reserved:
- size = 00.

- size = 11.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|----|-----------------------|
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 00, Q = x.
 - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- | | |
|------|----------------|
| 0:Rm | when size = 01 |
| M:Rm | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- | | |
|---|----------------|
| H | when size = 01 |
| S | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- | | |
|-------|----------------|
| H:L:M | when size = 01 |
| H:L | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.

Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else

```

```
Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;  
V[d] = result;
```

C7.2.318 UMLAL, UMLAL2 (vector)

Unsigned Multiply-Add Long (vector). This instruction multiplies the vector elements in the lower or upper half of the first source SIMD&FP register by the corresponding vector elements of the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLAL instruction extracts vector elements from the lower half of the first source register, while the UMLAL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UMLAL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

C7.2.319 UMLSL, UMLSL2 (by element)

Unsigned Multiply-Subtract Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMLSL instruction extracts vector elements from the lower half of the first source register, while the UMLSL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
boolean sub_op = (o2 == '1');
    
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 4S when size = 01
 - 2D when size = 10
 The following encodings are reserved:
 - size = 00.

- size = 11.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|----|-----------------------|
| 4H | when size = 01, Q = 0 |
| 8H | when size = 01, Q = 1 |
| 2S | when size = 10, Q = 0 |
| 4S | when size = 10, Q = 1 |
- The following encodings are reserved:
- size = 00, Q = x.
 - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- | | |
|------|----------------|
| 0:Rm | when size = 01 |
| M:Rm | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- | | |
|---|----------------|
| H | when size = 01 |
| S | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- | | |
|-------|----------------|
| H:L:M | when size = 01 |
| H:L | when size = 10 |
- The following encodings are reserved:
- size = 00.
 - size = 11.

Operation

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] - product;
    else

```

```
Elem[result, e, 2*esize] = Elem[operand3, e, 2*esize] + product;  
V[d] = result;
```

C7.2.320 UMLSL, UMLSL2 (vector)

Unsigned Multiply-Subtract Long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The UMLSL instruction extracts each source vector from the lower half of each source register, while the UMLSL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

C7.2.321 UMOV

Unsigned Move vector element to general-purpose register. This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias [MOV \(to general\)](#). See [Alias conditions](#) for details of when each alias is preferred.

32-bit variant

Applies when Q == 0.

UMOV <Wd>, <Vn>.<Ts>[<index>]

64-bit variant

Applies when Q == 1 && imm5 == x1000.

UMOV <Xd>, <Vn>.<Ts>[<index>]

Decode for all variants of this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
    when '0xxx1' size = 0; // UMOV Wd, Vn.B
    when '0xxx10' size = 1; // UMOV Wd, Vn.H
    when '0xx100' size = 2; // UMOV Wd, Vn.S
    when '1x1000' size = 3; // UMOV Xd, Vn.D
    otherwise UnallocatedEncoding();

integer idxsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

Alias conditions

| Alias | is preferred when |
|----------------------------------|-------------------|
| MOV (to general) | imm5 == 'x1000' |
| MOV (to general) | imm5 == 'xx100' |

Assembler symbols

- <Wd> Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
- <Xd> Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <Ts> For the 32-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
- B when imm5 = xxxx1
 - H when imm5 = xxx10
 - S when imm5 = xx100
- The encoding imm5 = xx000 is reserved.
- For the 64-bit variant: is an element size specifier, encoded in the "imm5" field. It can have the following values:
- D when imm5 = x1000
- The following encodings are reserved:
- imm5 = x0000.
 - imm5 = xxxx1.
 - imm5 = xxx10.
 - imm5 = xx100.
- <index> For the 32-bit variant: is the element index encoded in the "imm5" field. It can have the following values:
- imm5<4:1> when imm5 = xxxx1
 - imm5<4:2> when imm5 = xxx10
 - imm5<4:3> when imm5 = xx100
- The encoding imm5 = xx000 is reserved.
- For the 64-bit variant: is the element index encoded in "imm5<4>".

Operation

```
CheckFPAdvSIMDEnabled64();  
bits(idxsize) operand = V[n];  
  
X[d] = ZeroExtend(Elem[operand, index, esize], datasize);
```

C7.2.322 UMULL, UMULL2 (by element)

Unsigned Multiply Long (vector, by element). This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The UMULL instruction extracts vector elements from the lower half of the first source register, while the UMULL2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

Decode for this encoding

```

integer idxsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L); Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
    
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
 [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

4S when size = 01
 2D when size = 10

The following encodings are reserved:

- size = 00.
- size = 11.

- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
- The following encodings are reserved:
- size = 00, Q = x.
 - size = 11, Q = x.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "size:M:Rm" field. It can have the following values:
- 0:Rm when size = 01
 - M:Rm when size = 10
- The following encodings are reserved:
- size = 00.
 - size = 11.
- Restricted to V0-V15 when element size <Ts> is H.
- <Ts> Is an element size specifier, encoded in the "size" field. It can have the following values:
- H when size = 01
 - S when size = 10
- The following encodings are reserved:
- size = 00.
 - size = 11.
- <index> Is the element index, encoded in the "size:L:H:M" field. It can have the following values:
- H:L:M when size = 01
 - H:L when size = 10
- The following encodings are reserved:
- size = 00.
 - size = 11.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(idxsizesize) operand2 = V[m];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;

element2 = Int(Elem[operand2, index, esize], unsigned);
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    product = (element1*element2)<2*esize-1:0>;
    Elem[result, e, 2*esize] = product;

V[d] = result;
```

C7.2.323 UMULL, UMULL2 (vector)

Unsigned Multiply long (vector). This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The UMULL instruction extracts each source vector from the lower half of each source register, while the UMULL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, 2*esize] = (element1*element2)<2*esize-1:0>;

V[d] = result;
```

C7.2.324 UQADD

Unsigned saturating Add. This instruction adds the values of corresponding elements of the two source SIMD&FP registers, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQADD <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

Vector

Vector variant

UQADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

| | |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |

- D when size = 11
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1
- The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer sum;
boolean sat;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    (Elem[result, e, esize], sat) = SatQ(sum, esize, unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
    
```

C7.2.325 UQRSHL

Unsigned saturating Rounding Shift Left (register). This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see [UQSHL \(immediate\)](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQRSHL <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

Vector

Vector variant

UQRSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

Assembler symbols

| | |
|------|---|
| <V> | Is a width specifier, encoded in the "size" field. It can have the following values: B when size = 00 H when size = 01 S when size = 10 D when size = 11 |
| <d> | Is the number of the SIMD&FP destination register, in the "Rd" field. |

| <m> | Is the number of the second SIMD&FP source register, encoded in the "Rm" field. |
| <Vd> | Is the name of the SIMD&FP destination register, encoded in the "Rd" field. |
| <T> | Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values: 8B when size = 00, Q = 0 16B when size = 00, Q = 1 4H when size = 01, Q = 0 8H when size = 01, Q = 1 2S when size = 10, Q = 0 4S when size = 10, Q = 1 2D when size = 11, Q = 1 The encoding size = 11, Q = 0 is reserved. |
| <Vn> | Is the name of the first SIMD&FP source register, encoded in the "Rn" field. |
| <Vm> | Is the name of the second SIMD&FP source register, encoded in the "Rm" field. |

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1); // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

C7.2.326 UQRSHRN, UQRSHRN2

Unsigned saturating Rounded Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see [UQSHRN](#), [UQSHRN2](#).

The UQRSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQRSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQRSHRN <Vb><d>, <Va><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then ReservedValue();
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = esize;
integer elements = 1;
integer part = 0;

integer shift = (2 * esize) - UInt(immh:immb);  
boolean round = (op == '1');  
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0
16B when immh = 0001, Q = 1
4H when immh = 001x, Q = 0
8H when immh = 001x, Q = 1
2S when immh = 01xx, Q = 0
4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001
4S when immh = 001x
2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001
H when immh = 001x
S when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001
S when immh = 001x
D when immh = 01xx

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

The following encodings are reserved:

- `immh = 0000`.
- `immh = 1xxx`.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

`(16-UInt(immh:immb))` when `immh = 0001`

`(32-UInt(immh:immb))` when `immh = 001x`

`(64-UInt(immh:immb))` when `immh = 01xx`

See [Advanced SIMD modified immediate on page C4-237](#) when `immh = 0000`.

The encoding `immh = 1xxx` is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.327 UQSHL (immediate)

Unsigned saturating Shift Left (immediate). This instruction takes each vector element in the source SIMD&FP register, shifts it by an immediate value, places the results in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see [UQRSHL](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQSHL <V><d>, <V><n>, #<shift>

Decode for this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immh) - esize;

boolean src_unsigned;
boolean dst_unsigned;
case op:U of
    when '00' UnallocatedEncoding();
    when '01' src_unsigned = FALSE; dst_unsigned = TRUE;
    when '10' src_unsigned = FALSE; dst_unsigned = FALSE;
    when '11' src_unsigned = TRUE; dst_unsigned = TRUE;
    
```

Vector

Vector variant

UQSHL <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
    
```

```
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;

boolean src_unsigned;
boolean dst_unsigned;
case op:U of
  when '00' UnallocatedEncoding();
  when '01' src_unsigned = FALSE; dst_unsigned = TRUE;
  when '10' src_unsigned = FALSE; dst_unsigned = FALSE;
  when '11' src_unsigned = TRUE; dst_unsigned = TRUE;
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:

| (UInt(immh:immb)-32) | when immh = 01xx |
| (UInt(immh:immb)-64) | when immh = 1xxx |

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;
boolean sat;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], src_unsigned) << shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, dst_unsigned);
    if sat then FPSR.QC = '1';

V[d] = result;
```

C7.2.328 UQSHL (register)

Unsigned saturating Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see [UQRSHL](#).

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQSHL <V><d>, <V><n>, <V><m>

Decode for this encoding

```

  else
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

C7.2.329 UQSHRN, UQSHRN2

Unsigned saturating Shift Right Narrow (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see [UQRSHRN](#), [UQRSHRN2](#).

The UQSHRN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQSHRN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQSHRN <Vb><d>, <Va><n>, #<shift>

Decode for this encoding

```

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
```

```
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vb> Is the destination width specifier, encoded in the "immh" field. It can have the following values:

B when immh = 0001

H when immh = 001x

S when immh = 01xx

The following encodings are reserved:

- immh = 0000.

- immh = 1xxx.

<d> Is the number of the SIMD&FP destination register, in the "Rd" field.

<Va> Is the source width specifier, encoded in the "immh" field. It can have the following values:

H when immh = 0001

S when immh = 001x

D when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

<n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

The following encodings are reserved:

- immh = 0000.
- immh = 1xxx.

For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the "immh:immb" field. It can have the following values:

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

Vpart[d, part] = result;
```

C7.2.330 UQSUB

Unsigned saturating Subtract. This instruction subtracts the element values of the second source SIMD&FP register from the corresponding element values of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQSUB <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

Vector

Vector variant

UQSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

| | |
|---|----------------|
| B | when size = 00 |
| H | when size = 01 |
| S | when size = 10 |

- D when size = 11
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <m> Is the number of the second SIMD&FP source register, encoded in the "Rm" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
- 16B when size = 00, Q = 1
- 4H when size = 01, Q = 0
- 8H when size = 01, Q = 1
- 2S when size = 10, Q = 0
- 4S when size = 10, Q = 1
- 2D when size = 11, Q = 1
- The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;
boolean sat;

for e = 0 to elements-1
  element1 = Int(Elem[operand1, e, esize], unsigned);
  element2 = Int(Elem[operand2, e, esize], unsigned);
  diff = element1 - element2;
  (Elem[result, e, esize], sat) = SatQ(diff, esize, unsigned);
  if sat then FPSR.QC = '1';

V[d] = result;
  
```

C7.2.331 UQXTN, UQXTN2

Unsigned saturating extract Narrow. This instruction reads each vector element from the source SIMD&FP register, saturates each value to half the original width, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

The UQXTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the UQXTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

UQXTN <Vb><d>, <Va><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer part = 0;
integer elements = 1;

boolean unsigned = (U == '1');
```

Vector

Vector variant

UQXTN{2} <Vd>.<Tb>, <Vn>.<Ta>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

 S when size = 01
 D when size = 10
 The encoding size = 11 is reserved.
- <n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;
bits(2*esize) element;
boolean sat;

for e = 0 to elements-1
  element = Elem[operand, e, 2*esize];
  (Elem[result, e, esize], sat) = SatQ(Int(element, unsigned), esize, unsigned);
  
```

```
    if sat then FPSR.QC = '1';  
    Vpart[d, part] = result;
```

C7.2.332 URECPE

Unsigned Reciprocal Estimate. This instruction reads each vector element from the source SIMD&FP register, calculates an approximate inverse for the unsigned integer value, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

URECPE <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then ReservedValue();
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
 - 2S when sz = 0, Q = 0
 - 4S when sz = 0, Q = 1
 The encoding sz = 1, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRecipEstimate(element);

V[d] = result;
```

C7.2.333 URHADD

Unsigned Rounding Halving Add. This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see [UHADD](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type variant

URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0
 - 4S when size = 10, Q = 1
 The encoding size = 11, Q = x is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
```

```
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    Elem[result, e, esize] = (element1+element2+1)<esize:1>;

V[d] = result;
```

C7.2.334 URSHL

Unsigned Rounding Shift Left (register). This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

URSHL <V><d>, <V><n>, <V><m>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
if S == '0' && size != '11' then ReservedValue();
```

Vector

Vector variant

URSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

  Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

C7.2.336 URSQRTE

Unsigned Reciprocal Square Root Estimate. This instruction reads each vector element from the source SIMD&FP register, calculates an approximate inverse square root for each value, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector variant

URSQRTE <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then ReservedValue();
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "sz:Q" field. It can have the following values:
 - 2S when sz = 0, Q = 0
 - 4S when sz = 0, Q = 1
 - The encoding sz = 1, Q = x is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRSqrtEstimate(element);

V[d] = result;
```

C7.2.337 URSRA

Unsigned Rounding Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see [USRA](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

URSRA <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector

Vector variant

URSRA <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
 D when immh = 1xxx
 The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.

    else
        ELem[result, e, esize] = element<esize-1:0>;

V[d] = result;

```

C7.2.339 USHLL, USHLL2

Unsigned Shift Left Long (immediate). This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The USHLL instruction extracts vector elements from the lower half of the source register, while the USHLL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2. See *Alias conditions* for details of when each alias is preferred.

Vector variant

USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

| Alias | is preferred when |
|-------------|--------------------------------------|
| UXTL, UXTL2 | immb == '000' && BitCount(immh) == 1 |

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:
 - 8H when immh = 0001
 - 4S when immh = 001x

2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the "immh:immb" field. It can have the following values:

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

C7.2.340 USHR

Unsigned Shift Right (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see [URSHR](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

USHR <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector

Vector variant

USHR <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
 D when immh = 1xxx
 The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
 8B when immh = 0001, Q = 0
 16B when immh = 0001, Q = 1
 4H when immh = 001x, Q = 0
 8H when immh = 001x, Q = 1
 2S when immh = 01xx, Q = 0
 4S when immh = 01xx, Q = 1
 2D when immh = 1xxx, Q = 1
 See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.
 The encoding immh = 1xxx, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
 (128-UInt(immh:immb)) when immh = 1xxx
 The encoding immh = 0xxx is reserved.
 For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
 (16-UInt(immh:immb)) when immh = 0001
 (32-UInt(immh:immb)) when immh = 001x
 (64-UInt(immh:immb)) when immh = 01xx
 (128-UInt(immh:immb)) when immh = 1xxx
 See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;

```

C7.2.341 USQADD

Unsigned saturating Accumulate of Signed value. This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit [FPSR.QC](#) is set.

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

USQADD <V><d>, <V><n>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean unsigned = (U == '1');
```

Vector

Vector variant

USQADD <Vd>.<T>, <Vn>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the "size" field. It can have the following values:

B when size = 00

- H when size = 01
S when size = 10
D when size = 11
- <d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.
- <n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- 8B when size = 00, Q = 0
16B when size = 00, Q = 1
4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
2D when size = 11, Q = 1
The encoding size = 11, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation for all encodings

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.2.342 USRA

Unsigned Shift Right and Accumulate (immediate). This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see [URSRA](#).

Depending on the settings in the [CPACR_EL1](#), [CPTR_EL2](#), and [CPTR_EL3](#) registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Scalar

Scalar variant

USRA <V><d>, <V><n>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector

Vector variant

USRA <Vd>.<T>, <Vn>.<T>, #<shift>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE "Advanced SIMD modified immediate";
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immh);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

- <V> Is a width specifier, encoded in the "immh" field. It can have the following values:
 D when immh = 1xxx
 The encoding immh = 0xxx is reserved.
- <d> Is the number of the SIMD&FP destination register, in the "Rd" field.
- <n> Is the number of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:
 8B when immh = 0001, Q = 0
 16B when immh = 0001, Q = 1
 4H when immh = 001x, Q = 0
 8H when immh = 001x, Q = 1
 2S when immh = 01xx, Q = 0
 4S when immh = 01xx, Q = 1
 2D when immh = 1xxx, Q = 1
 See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.
 The encoding immh = 1xxx, Q = 0 is reserved.
- <Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.
- <shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the "immh:immb" field. It can have the following values:
 (128-UInt(immh:immb)) when immh = 1xxx
 The encoding immh = 0xxx is reserved.
 For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the "immh:immb" field. It can have the following values:
 (16-UInt(immh:immb)) when immh = 0001
 (32-UInt(immh:immb)) when immh = 001x
 (64-UInt(immh:immb)) when immh = 01xx
 (128-UInt(immh:immb)) when immh = 1xxx
 See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

Operation for all encodings

```

CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
    
```

C7.2.343 USUBL, USUBL2

Unsigned Subtract Long. This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The USUBL instruction extracts each source vector from the lower half of each source register, while the USUBL2 instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

USUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
- | | |
|-----------|------------|
| [absent] | when Q = 0 |
| [present] | when Q = 1 |
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
- | | |
|----|----------------|
| 8H | when size = 00 |
| 4S | when size = 01 |
| 2D | when size = 10 |
- The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
- | | |
|-----|-----------------------|
| 8B | when size = 00, Q = 0 |
| 16B | when size = 00, Q = 1 |

4H when size = 01, Q = 0
8H when size = 01, Q = 1
2S when size = 10, Q = 0
4S when size = 10, Q = 1
The encoding size = 11, Q = x is reserved.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = Vpart[n, part];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.344 USUBW, USUBW2

Unsigned Subtract Wide. This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element in the lower or upper half of the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register.

The USUBW instruction extracts vector elements from the lower half of the first source register, while the USUBW2 instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type variant

USUBW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

- 2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:
 - [absent] when Q = 0
 - [present] when Q = 1
- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:
 - 8H when size = 00
 - 4S when size = 01
 - 2D when size = 10
 The encoding size = 11 is reserved.
- <Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.
- <Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize) operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.2.345 UXTL, UXTL2

Unsigned extend Long. This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The UXTL instruction extracts vector elements from the lower half of the source register, while the UXTL2 instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is an alias of the USHLL, USHLL2 instruction. This means that:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode for this instruction.

Vector variant

UXTL{2} <Vd>.<Ta>, <Vn>.<Tb>

is equivalent to

USHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0

and is the preferred disassembly when BitCount(immh) == 1.

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

- [absent] when Q = 0
- [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Ta> Is an arrangement specifier, encoded in the "immh" field. It can have the following values:

- 8H when immh = 0001
- 4S when immh = 001x
- 2D when immh = 01xx

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000.

The encoding immh = 1xxx is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Tb> Is an arrangement specifier, encoded in the "immh:Q" field. It can have the following values:

- 8B when immh = 0001, Q = 0
- 16B when immh = 0001, Q = 1
- 4H when immh = 001x, Q = 0
- 8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

See [Advanced SIMD modified immediate on page C4-237](#) when immh = 0000, Q = x.

The encoding immh = 1xxx, Q = x is reserved.

Operation

The description of [USHLL](#), [USHLL2](#) gives the operational pseudocode for this instruction.

C7.2.346 UZP1

Unzip vectors (primary). This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

———— **Note** ————

This instruction can be used with UZP2 to de-interleave two vectors.

The following figure shows an example of the operation of UZP1 and UZP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UZP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```

C7.2.347 UZP2

Unzip vectors (secondary). This instruction reads corresponding odd-numbered vector elements from the two source SIMD&FP registers, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

———— **Note** ————

This instruction can be used with UZP1 to de-interleave two vectors.

The following figure shows an example of the operation of UZP1 and UZP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

UZP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operandl = V[n];
bits(datasize) operandh = V[m];
bits(datasize) result;
integer e;

bits(datasize*2) zipped = operandh:operandl;
for e = 0 to elements-1
    Elem[result, e, esize] = Elem[zipped, 2*e+part, esize];

V[d] = result;
```

C7.2.348 XTN, XTN2

Extract Narrow. This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The XTN instruction writes the vector to the lower half of the destination register and clears the upper half, while the XTN2 instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|------|----|----|----|----|----|----|----|----|----|----|----|----|----|---|-----|----|--|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 5 4 | | | 0 |
| 0 | Q | 0 | 0 | 1 | 1 | 1 | 0 | size | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | Rn | | | Rd | | |

Vector variant

XTN{2} <Vd>.<Tb>, <Vn>.<Ta>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the "Q" field. It can have the following values:

[absent] when Q = 0
 [present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<Tb> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:

8B when size = 00, Q = 0
 16B when size = 00, Q = 1
 4H when size = 01, Q = 0
 8H when size = 01, Q = 1
 2S when size = 10, Q = 0
 4S when size = 10, Q = 1

The encoding size = 11, Q = x is reserved.

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

<Ta> Is an arrangement specifier, encoded in the "size" field. It can have the following values:

8H when size = 00

4S when size = 01
2D when size = 10
The encoding size = 11 is reserved.

Operation

```
CheckFPAdvSIMDEnabled64();  
bits(2*datasize) operand = V[n];  
bits(datasize) result;  
bits(2*esize) element;  
  
for e = 0 to elements-1  
  element = Elem[operand, e, 2*esize];  
  Elem[result, e, esize] = element<esize-1:0>;  
Vpart[d, part] = result;
```

C7.2.349 ZIP1

Zip vectors (primary). This instruction reads adjacent vector elements from the upper half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

———— **Note** ————

This instruction can be used with ZIP2 to interleave two vectors.

The following figure shows an example of the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ZIP1 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part * pairs;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```

C7.2.350 ZIP2

Zip vectors (secondary). This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

———— **Note** ————

This instruction can be used with ZIP1 to interleave two vectors.

The following figure shows an example of the operation of ZIP1 and ZIP2 with the arrangement specifier 8B.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD variant

ZIP2 <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

Decode for this encoding

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
integer part = UInt(op);
integer pairs = elements DIV 2;
```

Assembler symbols

- <Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.
- <T> Is an arrangement specifier, encoded in the "size:Q" field. It can have the following values:
 - 8B when size = 00, Q = 0
 - 16B when size = 00, Q = 1
 - 4H when size = 01, Q = 0
 - 8H when size = 01, Q = 1
 - 2S when size = 10, Q = 0

4S when size = 10, Q = 1

2D when size = 11, Q = 1

The encoding size = 11, Q = 0 is reserved.

<Vn> Is the name of the first SIMD&FP source register, encoded in the "Rn" field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer base = part * pairs;
integer p;

for p = 0 to pairs-1
    Elem[result, 2*p+0, esize] = Elem[operand1, base+p, esize];
    Elem[result, 2*p+1, esize] = Elem[operand2, base+p, esize];

V[d] = result;
```

Part D

The AArch64 System Level Architecture

Chapter D1

The AArch64 System Level Programmers' Model

This chapter describes the AArch64 system level programmers' model. It contains the following sections:

- *Exception levels* on page D1-1498.
- *Exception terminology* on page D1-1499.
- *Execution state* on page D1-1501.
- *Security state* on page D1-1502.
- *Virtualization* on page D1-1504.
- *Registers for instruction processing and exception handling* on page D1-1507.
- *Process state, PSTATE* on page D1-1513.
- *Program counter and stack pointer alignment* on page D1-1515.
- *Reset* on page D1-1517.
- *Exception entry* on page D1-1521.
- *Exception return* on page D1-1536.
- *The Exception level hierarchy* on page D1-1540.
- *Synchronous exception types, routing and priorities* on page D1-1547.
- *Asynchronous exception types, routing, masking and priorities* on page D1-1555.
- *Configurable instruction enables and disables, and trap controls* on page D1-1562.
- *System calls* on page D1-1598.
- *Mechanisms for entering a low-power state* on page D1-1599.
- *Self-hosted debug* on page D1-1604.
- *The Performance Monitors Extension* on page D1-1606.
- *Interprocessing* on page D1-1607.
- *The effect of implementation choices on the programmers' model* on page D1-1619.

D1.1 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL n is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

Note

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers' model on page D1-1619 shows some example implementations.

When executing in AArch64 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within a particular Security state. *The ARMv8-A security model on page D1-1502* describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then when execution is at EL3, the PE can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see *Chapter D4 The AArch64 Virtual Memory System Architecture*.

D1.1.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

| | |
|------------|--|
| EL0 | Applications. |
| EL1 | OS kernel and associated functions that are typically described as <i>privileged</i> . |
| EL2 | Hypervisor. |
| EL3 | Secure monitor. |

D1.2 Exception terminology

The following subsections define the terms used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions on page D1-1500.](#)

D1.2.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state the exception is *taken from*. The PE state immediately after taking the exception is the state the exception is *taken to*.

D1.2.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state the exception *returns to*.

D1.2.3 Exception levels

An Exception level, EL_n , with a larger value of n than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example, EL_3 is a higher Exception level than EL_1 .

An Exception level with a smaller value of n than another Exception level is described as being a *lower* Exception level than the other Exception level. For example, EL_0 is a lower Exception level than EL_1 .

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

D1.2.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the *SError interrupt*, all exceptions taken to AArch64 state are required to be precise. For each occurrence of an *SError interrupt*, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch64 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by the instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address used by the instruction.

Also, for Data Aborts from load or store instructions executed in AArch64 state, where the Data Abort is taken synchronously:

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

Examples of instructions that perform more than one single-copy atomic memory access are the AArch32 LDM and STM instructions and the AArch64 LDP and STP instructions.

———— **Note** —————

- For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page B2-82](#).

D1.2.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

For more information about synchronous exceptions, see [Synchronous exception types, routing and priorities on page D1-1547](#).

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about asynchronous exceptions, see [Asynchronous exception types, routing, masking and priorities on page D1-1555](#).

D1.3 Execution state

The Execution states are:

AArch64 The 64-bit Execution state.

AArch32 The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

[Execution state on page A1-33](#) gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
 - At reset.
 - On a change of Exception level.

Note

- [Typical Exception level usage model on page D1-1498](#) shows which Exception levels different software layers might typically use.
 - [The effect of implementation choices on the programmers' model on page D1-1619](#) gives information on supported configurations of Exception levels and Execution states.
-

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. [Interprocessing on page D1-1607](#) describes this.

D1.4 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

- | | |
|-------------------------|---|
| Secure state | When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space. |
| Non-secure state | When in this state, the PE: <ul style="list-style-type: none">• Can access only the Non-secure physical address space.• Cannot access the Secure system control resources. |

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see [About the Virtual Memory System Architecture \(VMSA\)](#) on page D4-1722.

D1.4.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
 - EL3 exists only in Secure state.
 - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
 - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
 - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
 - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
 - Non-secure state if the implementation includes EL2.

Security model when EL3 is using AArch64

[Figure D1-1 on page D1-1503](#) shows the security model when EL3 is using AArch64. The figure shows how instances of EL0 and EL1 are present in both Security states. It also shows the expected software usage of the different Exception levels.

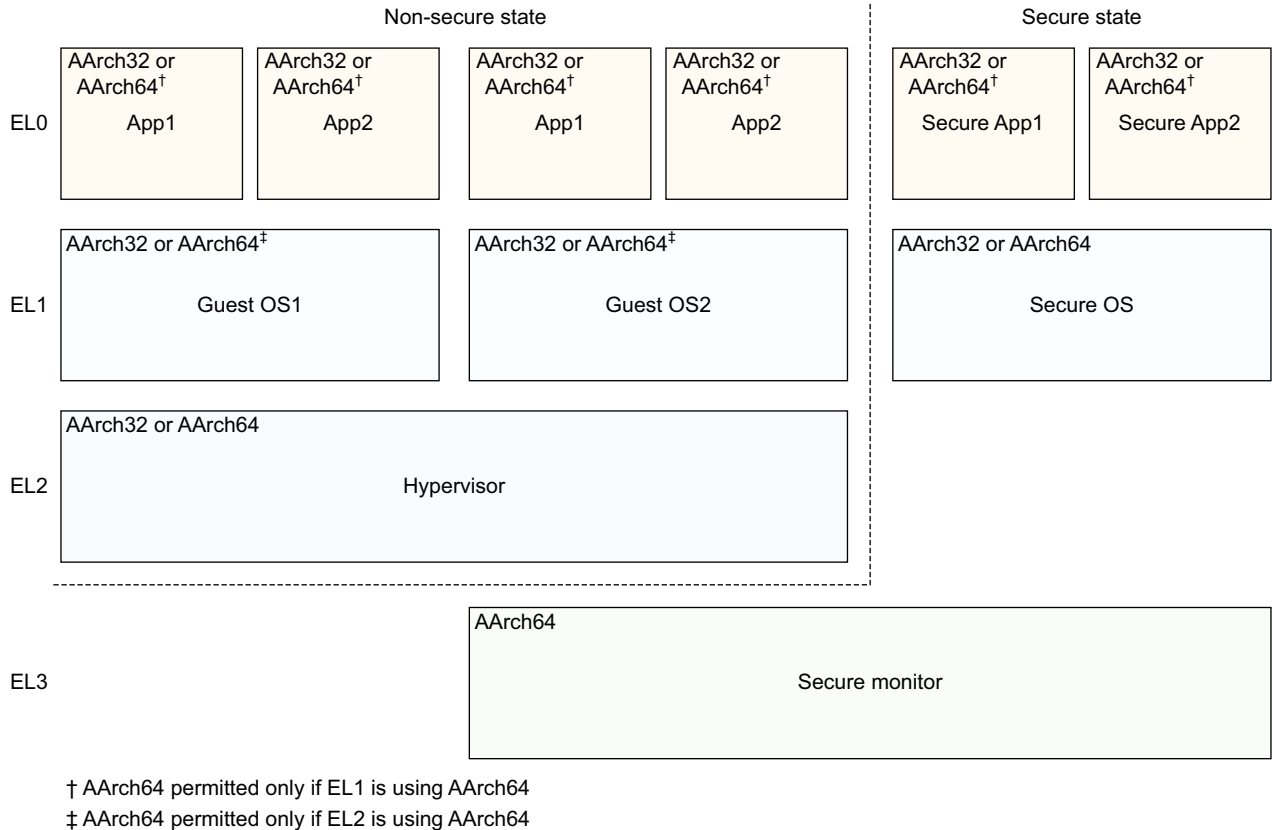

Figure D1-1 ARMv8-A security model when EL3 is using AArch64

For an overview of the Security model when EL3 is using AArch32, see [Figure G1-1 on page G1-3790](#).

D1.5 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine comprises Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems. A Guest OS runs on a virtual machine in Non-secure EL1.
- For each Guest operating system, applications, that run on the virtual machine of that Guest OS, usually in Non-secure EL0.

Note

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2. See [Configurable instruction enables and disables, and trap controls on page D1-1562](#).
- Route interrupts to the appropriate one of:
 - The current Guest OS.
 - A Guest OS that is not currently running.
 - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the EL1&0 translation regime, address translation occurs in two stages:
 - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
 - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

D1.5.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [EL2 configurable controls on page D1-1571](#), describes these.
- All of the virtual interrupts:
 - Virtual SError.
 - Virtual IRQ.
 - Virtual FIQ.

Hypervisor call exceptions taken from EL3 are taken to EL3. Otherwise, Hypervisor call exceptions are taken from Non-secure state to EL2.

All virtual interrupts are always taken to Non-secure EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, in Non-secure state its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3.

For more information, see [Asynchronous exception types, routing, masking and priorities](#) on page D1-1555.

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
 - [Routing exceptions to EL2](#) on page D1-1548.
 - [Routing debug exceptions](#) on page D2-1631.
- Provides mechanisms to trap Non-secure PE operations to EL2. See [EL2 configurable controls](#) on page D1-1571.
 - When an operation is trapped to EL2, the hypervisor typically either:
 - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
 - Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table D1-1](#).

Table D1-1 The virtual interrupt

| Physical interrupt | Corresponding virtual interrupt |
|--------------------|---------------------------------|
| SError | Virtual SError |
| IRQ | Virtual IRQ |
| FIQ | Virtual FIQ |

Software executing in EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. [Example D1-1](#) shows a usage model for virtual interrupts.

Example D1-1 Virtual interrupt usage model

A virtual interrupt usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
 - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
 - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

A hypervisor can prevent Non-secure EL1 and Non-secure EL0 from distinguishing a virtual interrupt from a physical interrupt.

For more information see:

- [Asynchronous exception types, routing, masking and priorities](#) on page D1-1555.
- [Virtual interrupts](#) on page D1-1558.

D1.6 Registers for instruction processing and exception handling

In the ARM architecture, registers fall into two main categories:

- Registers that provide system control or status reporting. These are described in [Chapter D7 AArch64 System Register Descriptions](#).
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions. This section introduces these registers, for execution in AArch64 state.

This section contains the following subsections:

- [The general purpose registers, R0-R30](#).
- [The stack pointer registers](#).
- [The SIMD and floating-point registers, V0-V31 on page D1-1508](#).
- [Saved Program Status Registers \(SPSRs\) on page D1-1508](#).
- [Exception Link Registers \(ELRs\) on page D1-1511](#).

D1.6.1 The general purpose registers, R0-R30

The general purpose register bank is used when processing instructions in the base instruction set. It comprises 31 general purpose registers, R0-R30.

These registers can be accessed as 31 64-bit registers, X0-X30, or 31 32-bit registers, W0-W30. See [Register size on page C6-432](#).

For information on the format of these registers, see [Registers in AArch64 state on page B1-59](#).

D1.6.2 The stack pointer registers

In AArch64 state, in addition to the general purpose registers, a dedicated stack pointer register is implemented for each implemented Exception level. The stack pointer registers are:

- [SP_ELO](#) and [SP_EL1](#).
- If the implementation includes EL2, [SP_EL2](#).
- If the implementation includes EL3, [SP_EL3](#).

————— Note —————

The four stack pointer register names define an architecture state requirement for four registers. For information on how to access these registers, and access restrictions, see [Special-purpose registers on page C5-293](#).

For information on stack pointer alignment restrictions, see [SP alignment checking on page D1-1515](#).

Stack pointer register selection

When executing at EL0, the PE uses the EL0 stack pointer, [SP_ELO](#).

When executing at any other Exception level, the PE can be configured to use either [SP_ELO](#) or the stack pointer for that Exception level, [SP_ELx](#).

By default, taking an exception selects the stack pointer for the target Exception level, [SP_ELx](#). For example, taking an exception to EL1 selects [SP_EL1](#). Software executing at the target Exception level can then choose to change the stack pointer to [SP_ELO](#) by updating [PSTATE.SP](#).

This applies even if taking the exception does not change the Exception level. For example, if the PE is executing at EL1 and the PE is using the [SP_ELO](#) stack pointer, then on taking an exception that targets EL1, the stack pointer changes to [SP_EL1](#).

The selected stack pointer can be indicated by a suffix to the Exception level:

- | | |
|----------|--|
| t | Indicates use of the SP_ELO stack pointer. |
| h | Indicates use of the SP_ELx stack pointer. |

———— **Note** ————

The t and h suffixes are based on the terminology of *thread* and *handler*, introduced in ARMv7-M

Table D1-2 shows the set of stack pointer options.

Table D1-2 AArch64 stack pointer options

| Exception level | AArch64 stack pointer options |
|-----------------|-------------------------------|
| EL0 | EL0t |
| EL1 | EL1t, EL1h |
| EL2 | EL2t, EL2h |
| EL3 | EL3t, EL3h |

D1.6.3 The SIMD and floating-point registers, V0-V31

The SIMD and floating-point instructions share a common bank of registers for floating-point, vector, and other SIMD-related scalar operations.

The SIMD and floating-point register bank comprises 32 quadword (128-bit) registers, V0-V31.

These registers can be accessed as:

- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.

For information on the format of these registers, see *Registers in AArch64 state* on page B1-59.

D1.6.4 Saved Program Status Registers (SPSRs)

The *Saved Program Status Registers* (SPSRs) are used to save PE state on taking exceptions.

In AArch64 state, there is an SPSR at each Exception level exceptions can be taken to, as follows:

- [SPSR_EL1](#), for exceptions taken to EL1 using AArch64.
- If EL2 is implemented, [SPSR_EL2](#), for exceptions taken to EL2 using AArch64.
- If EL3 is implemented, [SPSR_EL3](#), for exceptions taken to EL3 using AArch64.

———— **Note** ————

Exceptions cannot be taken to EL0.

When the PE takes an exception, the PE state is saved from PSTATE in the [SPSR](#) at the Exception level the exception is taken to. For example, if the PE takes an exception to EL1, the PE state is saved in [SPSR_EL1](#). For more information on [PSTATE](#), see *Process state, PSTATE* on page D1-1513.

Saving the PE state means the exception handler can:

- On return from the exception, restore the PE state to the state stored in the [SPSR](#) at the Exception level the exception is returning from. For example, on returning from EL1, the PE state is restored to the state stored in [SPSR_EL1](#).
- Examine the value that PSTATE had when the exception was taken, for example to determine the Execution state and Exception level in which the instruction that caused an exception was executed.

Note

- All PSTATE fields are saved, including those which have no direct read and write access, and those that are meaningful only in AArch32 state.
- Those PSTATE fields that are meaningful only in AArch32 state are saved when an exception is taken from AArch32 state to AArch64 state.

The SPSRs are UNKNOWN on reset.

SPSR format for exceptions taken to AArch64 state

Exceptions can be taken to AArch64 state from AArch64 state or AArch32 state:

- For an exception taken to AArch64 state from AArch64 state, the SPSR bit assignments are:

- For an exception taken to AArch64 state from AArch32 state, the SPSR bit assignments are:

The following list describes the bit assignments:

N, Z, C, V, bits[31:28]

Shows the values of the **PSTATE**.{N, Z, C, V} condition flags immediately before the exception was taken.

Bits[27:22] Reserved, RES0, for exceptions taken from AArch64 state.

For exceptions taken from AArch32 state:

Q, bit[27]

Shows the value of **PSTATE**.Q immediately before the exception was taken.

IT[1:0], bits[26:25]

See [Bits\[19:10\] on page D1-1510](#).

J, bit[24]

Shows the value of **PSTATE**.J immediately before the exception was taken. This bit is RES0.

For the definitions of the Q, IT, and J fields, see [Process state, PSTATE on page G1-3805](#).

SS, bit[21] The Software Step bit.

SPSR_ELx.SS is used by a debugger to initiate a Software Step exception. The SS bit also indicates which software step state machine state the PE was in. See [Software Step exceptions on page D2-1673](#).

IL, bit[20] Illegal Execution state bit. Shows the value of **PSTATE**.IL immediately before the exception was taken. See [Illegal return events from AArch64 state on page D1-1537](#).

- Bits[19:10]** Reserved, RES0, for exceptions taken from AArch64 state.
For exceptions taken from AArch32 state:
- GE[3:0], bits [19:16]**
Shows the value of `PSTATE.GE` immediately before the exception was taken.
- IT[7:2], bits [15:10]**
In conjunction with `IT[1:0]`, shows the value of `PSTATE.IT` before the exception was taken.
- For definitions of the GE and IT fields, see *Process state, PSTATE* on page G1-3805.
- Bit[9]** D, the debug exception mask bit, for exceptions taken from AArch64 state. Shows the value of `PSTATE.D` immediately before the exception was taken. See *The PSTATE debug mask bit, D* on page D1-1604.
- E, for exceptions taken from AArch32 state. Shows the value of `PSTATE.E` immediately before the exception was taken. For the definition of the E bit, see *Process state, PSTATE* on page G1-3805.
- A, I, F, bits[8:6]**
Shows the values of the `PSTATE.{A,I,F}` exception mask bits immediately before the exception was taken:
- A, bit[8]** SError interrupt mask bit.
I, bit[7] IRQ mask bit.
F, bit[6] FIQ mask bit.
- See *Asynchronous exception masking* on page D1-1557.
- Bit[5]** Reserved, RES0, for exceptions taken from AArch64 state.
T, for exceptions taken from AArch32 state. Shows the value of `PSTATE.T` immediately before the exception was taken.
- M[4:0], bits[4:0]**
Mode field.
- **Note** —————
- The name of this field is inherited from ARMv7, where the M field specified the PE *mode*.
- For exceptions taken from AArch64 state:
- M[4]** The value of this is 0. M[4] encodes the value of `PSTATE.nRW`, that indicates the Execution state from which the exception was taken.
- M[3:0]** Encodes the Exception level and the stack pointer register selection, as shown in [Table D1-3](#).

Table D1-3 M[3:0] encodings, for exceptions taken from AArch64 state

| M[3:0] ^a | Exception level and stack pointer |
|---------------------|-----------------------------------|
| 0b1101 | EL3h |
| 0b1100 | EL3t |
| 0b1001 | EL2h |
| 0b1000 | EL2t |
| 0b0101 | EL1h |
| 0b0100 | EL1t |
| 0b0000 | EL0t |

a. All M[3:0] encodings not shown in the table are reserved.

The M[3:0] encoding comprises:

- M[3:2]** Encodes the Exception level, 0-3.
- M[1]** Reserved, RES0. If set to 1 at the time of an exception return, then that exception return is treated as an Illegal Execution state exception return.
- M[0]** Selects the SP:
 - 0** [SP_EL0](#). Indicated by a t suffix on the Exception level.
 - 1** [SP_ELx](#), where *x* is the value of M[3:2]. Indicated by an h suffix on the Exception level.

See [Stack pointer register selection on page D1-1507](#).

For exceptions taken from AArch32 state:

- M[4]** The value of this is 1. M[4] encodes the value of [PSTATE.nRW](#), that indicates the Execution state from which the exception was taken.
- M[3:0]** Encodes the AArch32 mode that the PE was in immediately before the exception was taken, as shown in [Table D1-4](#).

Table D1-4 M[3:0] encodings, for exceptions taken from AArch32 state

| M[3:0] | AArch32 PE mode |
|--------|-----------------|
| 0b0000 | User |
| 0b0001 | FIQ |
| 0b0010 | IRQ |
| 0b0011 | Supervisor |
| 0b0111 | Abort |
| 0b1010 | Hyp |
| 0b1011 | Undefined |
| 0b1111 | System |

Bits [27:22] and [19:10] of an SPSR are ignored on an exception return to AArch64 state. Bits [23:22] of an [SPSR](#) are ignored on an exception return to AArch32 state.

Pseudocode description of SPSR operations

The [SPSR\[\]](#) pseudocode function accesses the current SPSR, and is common to AArch32 and AArch64 operations.

The [SetPSTATEFromPSR\(\)](#) pseudocode function updates [PSTATE](#) from an SPSR.

D1.6.5 Exception Link Registers (ELRs)

Exception Link Registers hold preferred exception return addresses.

Whenever the PE takes an exception, the preferred return address is saved in the ELR at the Exception level the exception is taken to. For example, whenever the PE takes an exception to EL1, the preferred return address is saved in [ELR_EL1](#).

On an exception return, the PC is restored to the address stored in the ELR. For example, on returning from EL1, the PC is restored to the address stored in [ELR_EL1](#).

AArch64 state provides an ELR for each Exception level exceptions can be taken to. The ELRs that AArch64 state provides are:

- [ELR_EL1](#), for exceptions taken to EL1.
- If EL2 is implemented, [ELR_EL2](#), for exceptions taken to EL2.

- If EL3 is implemented, [ELR_EL3](#), for exceptions taken to EL3.

On taking an exception from AArch32 state to AArch64 state, bits[63:32] of the ELR are set to zero.

The preferred return address depends on the nature of the exception. For more information, see [Preferred exception return address](#) on page D1-1521.

D1.7 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type `ProcState`. `ProcState` is defined in [Chapter J1 ARMv8 Pseudocode](#).

The PSTATE fields that are meaningful in AArch64 state are:

The condition flags

| | |
|----------|--------------------------|
| N | Negative Condition flag. |
| Z | Zero Condition flag. |
| C | Carry Condition flag. |
| V | Overflow Condition flag. |

[Process state, PSTATE on page B1-61](#) gives more information about these flags.

The Execution state controls

| | |
|------------|--|
| SS | Software Step bit, see Software Step exceptions on page D2-1673 . On a reset or taking an exception to AArch64 state, this bit is set to 0. |
| IL | Illegal Execution state bit, see The Illegal Execution state exception on page D1-1539 . On a reset or taking an exception to AArch64 state, this bit is set to 0. |
| nRW | Current Execution state, see Execution state on page D1-1501 . This bit is 0 when the current Execution state is AArch64. This bit is set to 0: <ul style="list-style-type: none"> • On reset into an Exception level that is using AArch64. • On taking an exception to an Exception level that is using AArch64. |
| EL | Current Exception level, see Exception levels on page D1-1498 . On a reset to AArch64 state, this field holds the encoding for the highest implemented Exception level. |

Note

The ARM architecture requires that a PE resets into the highest implemented Exception level.

| | |
|-----------|---|
| SP | Stack pointer register selection bit, see Stack pointer register selection on page D1-1507 . On a reset or taking an exception to AArch64 state, this bit is set to 1, meaning that SP_ELx is selected. |
|-----------|---|

The exception mask bits

| | | | | | | | |
|----------------|---|----------|----------------------------|----------|-------------------------|----------|-------------------------|
| D | Debug exception mask bit, see The PSTATE debug mask bit, D on page D1-1604 . On a reset or taking an exception to AArch64 state, this bit is set to 1. | | | | | | |
| A, I, F | Asynchronous exception mask bits: <table> <tr> <td>A</td> <td>SError interrupt mask bit.</td> </tr> <tr> <td>I</td> <td>IRQ interrupt mask bit.</td> </tr> <tr> <td>F</td> <td>FIQ interrupt mask bit.</td> </tr> </table> | A | SError interrupt mask bit. | I | IRQ interrupt mask bit. | F | FIQ interrupt mask bit. |
| A | SError interrupt mask bit. | | | | | | |
| I | IRQ interrupt mask bit. | | | | | | |
| F | FIQ interrupt mask bit. | | | | | | |

See [Asynchronous exception types, routing, masking and priorities on page D1-1555](#). On a reset or taking an exception to AArch64 state, each of these bits is set to 1.

D1.7.1 Accessing PSTATE fields

In AArch64 state, PSTATE fields can be accessed using Special-purpose registers that can be directly read using the [MRS](#) instruction, and directly written using the [MSR \(register\)](#) instructions. [Table D1-5](#) shows the Special-purpose registers that access the PSTATE fields that hold AArch64 state, when the PE is in AArch64 state. All other PSTATE fields do not have direct read and write access.

Table D1-5 Accessing PSTATE fields using MRS and MSR (register)

| Special-purpose register | PSTATE fields |
|---------------------------|---------------|
| NZCV | N, Z, C, V |
| DAIF | D, A, I, F |
| CurrentEL | EL |
| SPSel | SP |

Software can also use the [MSR \(immediate\)](#) instruction to directly write to PSTATE.{D, A, I, F, SP}. [Table D1-6](#) shows the [MSR \(immediate\)](#) operands that can directly write to these PSTATE fields when the PE is in AArch64 state.

Table D1-6 Accessing PSTATE.{D, A, I, F, SP} using MSR (immediate)

| Operand | PSTATE fields | Notes |
|-------------------------|---------------|--|
| DAIFSet | D, A, I, F | Directly sets any of the PSTATE.{D,A, I, F} bits to 1 |
| DAIFClr | D, A, I, F | Directly clears any of the PSTATE.{D, A, I, F} bits to 0 |
| SPSel | SP | Directly sets PSTATE.SP to either 1 or 0 |

PSTATE.{N, Z, C, V} can be accessed at EL0. Access to PSTATE.{D, A, I, F} at EL0 using AArch64 depends on [SCTLR_EL1.UMA](#), see [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1566](#). All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

Writes to the PSTATE fields have side-effects on various aspects of the PE operation. All of these side-effects are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

D1.7.2 The Saved Program Status Registers (SPSRs)

On taking an exception, PSTATE is preserved in the SPSR of the Exception level the exception is taken to. The SPSRs are described in [Saved Program Status Registers \(SPSRs\) on page D1-1508](#).

D1.8 Program counter and stack pointer alignment

This section contains the following:

- [PC alignment checking](#).
- [SP alignment checking](#).

D1.8.1 PC alignment checking

PC alignment checking generates an exception associated with instruction fetch if, in AArch64 state, there is an attempt to architecturally execute an instruction that was fetched with a misaligned PC. A misaligned PC is when bits[1:0] of the PC are not 0b00. 

———— **Note** ————

As with Instruction Aborts, speculative fetching of an instruction does not generate an exception. An exception occurs only on an attempt to architecturally execute the instruction.

If an exception is generated as a result of an instruction fetch at EL0, it is taken to EL1, unless the exception occurs in Non-secure state and [HCR_EL2.TGE](#) bit is 1, when it is taken to EL2 instead. If an exception is generated as a result of an instruction fetch at any other Exception level, the Exception level is unchanged.

A PC misalignment sets the EC field in the *Exception Syndrome Register* (ESR) to 0x22, for the ESR associated with the target Exception level.

When the exception is taken to an Exception level using AArch64, the associated Exception Link Register holds the entire PC in its misaligned form, as does the [FAR_ELx](#) for the Exception level that the exception is taken to.

[Exception return and PC alignment on page D1-1537](#) gives more information on PC alignment checking associated with exception returns.

———— **Note** ————

A misalignment of the PC is a common indication of a serious error, for example software corruption of an address.

The pseudocode function [AArch64.CheckPCAlignment\(\)](#) performs PC alignment checking in AArch64 state. When necessary it calls [AArch64.PCAlignmentFault\(\)](#) to generate an exception.

D1.8.2 SP alignment checking

A *misaligned stack pointer* is where bits[3:0] of the stack pointer are not 0b0000, when the stack pointer is used as the base address of the calculation, regardless of any offset applied by the instruction.

The PE can be configured so that if a load or store instruction uses a misaligned stack pointer, the PE generates an exception on the attempt to execute the instruction. In this configuration, [CheckSPAlignment\(\)](#) performs the stack pointer check, and calls [AArch64.SPAlignmentFault\(\)](#) if a misaligned stack pointer is found. 

———— **Note** ————

- As with Data Aborts, a speculative data access to memory using the stack pointer does not generate the exception. The exception occurs only on an attempt to architecturally execute the instruction.
- Prefetch memory abort instructions do not cause synchronous exceptions. See [Prefetch memory on page C3-156](#).

Stack pointer alignment checking is only performed in AArch64 state, and can be enabled for each Exception level as follows:

- [SCTLR_EL1](#).{SA0, SA} controls EL0 and EL1, respectively
- [SCTLR_EL2](#).SA controls EL2
- [SCTLR_EL3](#).SA controls EL3.

If an exception is generated as a result of a load or store at EL0, it is taken as an exception to EL1 unless the [HCR_EL2.TGE](#) bit is set in the Non-secure state, when it is taken to EL2. If an exception is generated as a result of a load or store at any other Exception level, the Exception level is unchanged.

A stack pointer misalignment sets the EC field to 0x26, in the ESR associated with the target Exception level. If memory alignment checking and stack pointer alignment checking are enabled, then an SP alignment fault has priority in setting the value of the EC field, in the ESR associated with the target Exception level.

The pseudocode function [CheckSPAlignment\(\)](#) performs the stack pointer alignment check. When necessary it calls [AArch64.SPAlignmentFault\(\)](#) to generate an exception.

D1.9 Reset

The ARMv8-A architecture supports the following resets:

- | | |
|-------------------|---|
| Cold reset | Resets all of the logic on which the PE executes, including the integrated debug functionality. In some contexts, this logic is described as belonging to the <i>Cold reset domain</i> . |
| Warm reset | Resets the logic on which the PE executes, but does not reset the integrated debug functionality. In some contexts, this logic is described as belonging to the <i>Warm reset domain</i> . |

Note

The ARMv8-A architecture also supports an *external debug reset*. See [External debug register resets on page H8-4981](#).

The difference between a Cold reset and a Warm reset is relevant only to the debug functionality and the [RMR_ELx](#) register, if an [RMR_ELx](#) register is implemented:

- A Warm reset permits debugging across a reset of the PE logic.
- Writing 1 to [RMR_ELx.RR](#) requests a Warm reset.

The mechanisms, other than [RMR_ELx.RR](#), to assert these resets are IMPLEMENTATION DEFINED. It is IMPLEMENTATION DEFINED whether:

- It is possible to independently assert an External Debug reset and a Cold reset.
- It is possible to assert a Warm reset, as opposed to asserting a Cold reset, other than by the use of [RMR_ELx.RR](#).

Note

ARM recommends that:

- If separate Core and Debug power domains are implemented, as described in [Reset and debug on page H6-4955](#), then a Cold reset can be asserted independently of External Debug reset.
 - A Warm reset can be asserted to permit debugging across a reset of the PE logic.
-

This means that an implementation can define other resets according to the requirements the implementation or system must fulfil. These other resets are outside the scope of the ARMv8-A architecture. However, they can be mapped onto the resets described here.

In the description that follows, the term *reset* is used in contexts where there is no difference between the effect of a Cold reset and the effect of a Warm reset.

On a reset, the PE enters the highest implemented Exception level.

If the highest implemented Exception level can use either Execution state, then:

- The implementation must include a *Reset Management Register* (RMR). Only one RMR is implemented. The RMR implemented is the RMR is associated with the highest Exception level.
- On a Cold reset, the Execution state entered is determined by a configuration input signal.
- On a Warm reset, the Execution state entered is determined by [RMR_ELx.AA64](#).

If the highest implemented Exception level is configured to use AArch64 state, then on reset:

- The stack pointer for the highest implemented Exception level, [SP_ELx](#), is selected.
- Execution starts at an IMPLEMENTATION DEFINED address, anywhere in the physical address range. The RVBAR associated with the highest implemented Exception level, [RVBAR_EL1](#), [RVBAR_EL2](#), or [RVBAR_EL3](#), holds this address.

The remainder of this section contains the following:

- [PE state on reset to AArch64 state](#).
- [Code sequence to use RMR_ELx.RR to request a Warm reset on page D1-1519](#).

For more information about reset see:

- [Behavior of caches at reset on page D3-1698](#).
- [TLB behavior at reset on page D4-1813](#).
- [Reset and debug on page H6-4955](#).

D1.9.1 PE state on reset to AArch64 state

———— Note ————

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch64 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- Each of the [PSTATE](#).{D, A, I, F} interrupt masks is set to 1.
- The Software step control bit, [PSTATE.SS](#), is set to 0.
- The IL process state bit, [PSTATE.IL](#), is set to 0.
- All general-purpose, and SIMD and floating-point registers are UNKNOWN.
- The ELR and SPSR for each Exception level are UNKNOWN.
- The stack pointer register for each Exception level is UNKNOWN.
- Unless explicitly defined in this subsection, each System register at each Exception level is in an architecturally UNKNOWN state.
- The TLBs and caches are in an IMPLEMENTATION DEFINED state. This means that the TLBs, the caches, or both, might require invalidation using IMPLEMENTATION DEFINED invalidation sequences before the memory management system is enabled or Normal memory accesses are permitted to be Cacheable.

———— Note ————

- On reset, System register Cacheability control fields force all Normal memory accesses to be treated as Non-cacheable. This applies only for the translation regime used by the Exception level and Security state entered on reset. For information about these controls see [Enabling and disabling the caching of memory accesses on page D3-1696](#).
 - The implementation might include IMPLEMENTATION DEFINED resets. If it does, each of these resets might treat the cache and TLB state differently. The ARMv8-A architecture permits this.
 - Different IMPLEMENTATION DEFINED invalidation sequences might be required for different IMPLEMENTATION DEFINED resets.
 - In some implementations, the IMPLEMENTATION DEFINED invalidation sequence might be a NOP.
-
- In the [SCTLR_ELx](#) for the highest implemented Exception level:
 - Each of the {M, C, I} bits is set to 0
 - The EE bit is set to an IMPLEMENTATION DEFINED value, typically defined by a configuration input.
 - If an RMR is implemented, [RMR_ELx.RR](#) is set to 0. ELx in this context is the highest implemented Exception level.
 - The enables for the counter event stream are set to 0. This means that the following bits are set to 0:
 - [CNTKCTL_EL1.EVNTEN](#).
 - If the implementation includes EL2, [CNTHCTL_EL2.EVNTEN](#).

- `PMCR_EL0.E` is set to 0.

———— **Note** ————

This means the Performance Monitors cannot assert interrupts at reset.

- `OSDLR_EL1.DLK` bit is set to 0.
- Each of `MDCCINT_EL1.{TX, RX}` is set to 0.
- `EDPRCR.CWRR` is set to 0.
- `EDPRSR.SR` is set to 1.
- If the implementation includes EL3, then each of `MDCR_EL3.{EPMAD, EDAD, SPME}` is set to 0.
- If the implementation includes EL2, then `MDCR_EL2.HPMN` is set to the value of `PMCR_EL0.N`.
- `EDESR.OSUC` is set to 0, and `EDESR.{SS, RC}` are set to the values of `EDECR.{SS, RCE}`.

———— **Note** ————

On an External debug reset, `EDECR.{SS, RCE}` are set to 0.

Additionally, for a Cold reset into AArch64 state:

- If an RMR is implemented, `RMR_ELx.AA64` is set to 1. ELx in this context is the highest implemented Exception level.
- Each of `MDCCSR_EL0.{TXfull, RXfull}` is set to 0.
- The `DBGPRCR_EL1.CORENPRDRQ` is set to the value of `EDPRCR.COREPURQ`.
An External Debug reset sets `EDPRCR.COREPURQ` to 0, see [External debug register resets on page H8-4981](#). If an External Debug reset and a Cold reset coincide, both `DBGPRCR_EL1.CORENPRDRQ` and `EDPRCR.COREPURQ` are reset to 0.
- The debug CLAIM bits are reset to 0.

———— **Note** ————

These are the bits that are set to 1 by writing to `DBGCLAIMSET_EL1.CLAIM`, and cleared to 0 by writing to `DBGCLAIMCLR_EL1.CLAIM`.

- Each of `EDSCR.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull}` is set to 0.

———— **Note** ————

`MDCCSR_EL0.{RXfull, TXfull}` reflect the values in `EDSCR.{RXfull, TXfull}`.

- Each of `EDECCR.{NSE, SE}` is set to 0.
- `OSLSR_EL1.OSLK` is set to 1.
- In the `EDPRSR`:
 - The SPMAD, SDAD fields are set to 0.
 - The SPD field is set to 1.

D1.9.2 Code sequence to use `RMR_ELx.RR` to request a Warm reset

The following assembler sequence uses `RMR_ELx.RR` to request a Warm reset:

```
; in addition, interrupts and debug requests for this core should be disabled
; in the system before running this sequence to ensure the WFI suspends execution
MOV Wy, #3 ; for AArch64, #2 for AArch32; y is any register
```

```
    DSB                ; ensure all stores etc are complete
    MSR RMR_ELx, Wy   ; request the reset
    ISB                ; synchronise change to the RMR
Loop
    WFI                ; enter a quiescent state
    B Loop
```

D1.9.3 Pseudocode description of reset

The `AArch64.TakeReset()` pseudocode function performs a reset into AArch64 state.

`AArch64.TakeReset()` calls the functions `AArch64.ResetGeneralRegisters()`, `AArch64.ResetSIMDFPRegisters()`, `AArch64.ResetSpecialRegisters()`, `AArch64.ResetSystemRegisters()`, and `ResetExternalDebugRegisters()`.

`AArch64.ResetSystemRegisters()` resets all System registers to their reset state as defined in the register descriptions in *PE state on reset to AArch64 state* on page D1-1518 and *Chapter D7 AArch64 System Register Descriptions*.

———— **Note** —————

The `AArch64.ResetSystemRegisters()` function only resets the System registers.

`ResetExternalDebugRegisters()` resets all external debug registers to their reset state as defined in the register descriptions in *Chapter H9 External Debug Register Descriptions*.

D1.10 Exception entry

Exceptions are targeted at particular Exception levels. The Exception level that an exception targets is either programmed by software, or is determined by the nature of the exception.

Under no circumstances do exceptions cause execution to move to a lower Exception level.

If an asynchronous exception targets a lower Exception level, the exception is not taken and remains pending. See [Asynchronous exception routing](#) on page D1-1556 and [Asynchronous exception masking](#) on page D1-1557.

———— Note —————

The construction of the architecture means that usually, it is impossible for an exception to target a lower Exception level.

The Security state can only change on taking an exception if the exception is taken from Non-secure state to EL3.

———— Note —————

Taking an exception to EL3 from any Exception level has no effect on the value of the [SCR_EL3.NS](#) bit.

On taking an exception to AArch64 state:

- The PE state is saved in the [SPSR_ELx](#) at the Exception level the exception is taken to. See [Saved Program Status Registers \(SPSRs\)](#) on page D1-1508.
- The preferred return address is saved in the [ELR_ELx](#) at the Exception level the exception is taken to. See [Exception Link Registers \(ELRs\)](#) on page D1-1511.
- All of [PSTATE](#).{D, A, I, F} are set to 1. See [Process state, PSTATE](#) on page D1-1513.
- If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the [ESR_ELx](#) at the Exception level the exception is taken to. See [Use of the ESR_EL1, ESR_EL2, and ESR_EL3](#) on page D1-1523.
- Execution moves to the target Exception level, and starts at the address defined by the exception vector. Which exception vector is used is also an indicator of whether the exception came from a lower Exception level or the current Exception level. See [Exception vectors](#) on page D1-1522.
- The stack pointer register selected is the dedicated stack pointer register for the target Exception level. See [The stack pointer registers](#) on page D1-1507.

The remainder of this section contains the following:

- [Preferred exception return address](#).
- [Exception vectors](#) on page D1-1522.
- [Pseudocode description of exception entry to AArch64 state](#) on page D1-1523.
- [Exception classes and the ESR_ELx syndrome registers](#) on page D1-1523.
- [Summary of register updates on faults taken to an Exception level that is using AArch64](#) on page D1-1535.

D1.10.1 Preferred exception return address

For an exception taken to an Exception level using AArch64, the Exception Link Register for that Exception level, [ELR_ELx](#), holds the preferred exception return address. The preferred exception return address depends on the nature of the exception, as follows:

- For asynchronous exceptions, it is the address of the instruction following the instruction boundary at which the interrupt occurs. Therefore, it is the address of the first instruction that did not execute, or did not complete execution, as a result of taking the interrupt.
- For synchronous exceptions other than system calls, it is the address of the instruction that generates the exception.

- For exception generating instructions, it is the address of the instruction that follows the exception generating instruction.

———— **Note** —————

If an exception generating instruction is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

When an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the top 32 bits of the modified `ELR_ELx` are 0.

D1.10.2 Exception vectors

When the PE takes an exception to an Exception level that is using AArch64, execution is forced to an address that is the *exception vector* for the exception. The exception vector exists in a *vector table* at the Exception level the exception is taken to.

A vector table occupies a number of consecutive word-aligned addresses in memory, starting at the *vector base address*.

Each Exception level has an associated *Vector Base Address Register* (VBAR), that defines the exception base address for the table at that Exception level.

For exceptions taken to AArch64 state, the vector table provides the following information:

- Whether the exception is one of the following:
 - Synchronous exception.
 - SError.
 - IRQ.
 - FIQ.
- Information about the Exception level that the exception came from, combined with information about the stack pointer in use, and the state of the register file.

Table D1-7 shows this.

Table D1-7 Vector offsets from vector table base address

| Exception taken from | Offset for exception type | | | |
|---|---------------------------|-------------|-------------|-------------------|
| | Synchronous | IRQ or vIRQ | FIQ or vFIQ | SError or vSError |
| Current Exception level with <code>SP_ELO</code> . | 0x000 | 0x080 | 0x100 | 0x180 |
| Current Exception level with <code>SP_ELx</code> , $x > 0$. | 0x200 | 0x280 | 0x300 | 0x380 |
| Lower Exception level, where the implemented level immediately lower than the target level is using AArch64. ^a | 0x400 | 0x480 | 0x500 | 0x580 |
| Lower Exception level, where the implemented level immediately lower than the target level is using AArch32. ^a | 0x600 | 0x680 | 0x700 | 0x780 |

a. For exceptions taken to EL3, if EL2 is implemented, the level immediately lower than the target level is EL2 if the exception was taken from Non-secure state, but EL1 if the exception was taken from Secure EL1 or EL0.

Reset is treated as a special vector for the highest implemented Exception level. This special vector uses an IMPLEMENTATION DEFINED address that is typically set either by a hardwired configuration of the PE or by configuration input signals. The `RVBAR_ELx` register contains this reset vector address, where x is the number of the highest implemented Exception level.

D1.10.3 Pseudocode description of exception entry to AArch64 state

The `AArch64.TakeException()` pseudocode function describes the behavior when the PE takes an exception to an Exception level that is using AArch64. The `AArch64.ExceptionClass()` function determines the EC (Exception class) and IL (Instruction length) values required to report the exception, and `AArch64.ReportException()` reports the exception.

The pseudocode functions `AArch64.TakeException()`, `AArch64.ExceptionClass()`, and `AArch64.ReportException()` are described in [Chapter J1 ARMv8 Pseudocode](#).

D1.10.4 Exception classes and the ESR_ELx syndrome registers

If the exception is a synchronous exception or an SError interrupt, information characterizing the reason for the exception is saved in the `ESR_ELx` at the Exception level the exception is taken to. The information saved is determined at the time the exception is taken, and is not changed as a result of the explicit synchronization that takes place at the start of taking the exception. See [Synchronization requirements for AArch64 System registers on page D7-1889](#). The following sections give more information:

- [Use of the ESR_EL1, ESR_EL2, and ESR_EL3](#).
- [Reporting the EC encoding when an exception is routed to EL2 on page D1-1535](#).

Use of the ESR_EL1, ESR_EL2, and ESR_EL3

An `ESR_ELx` holds the syndrome information for an exception that is taken to AArch64 state.

———— **Note** ————

This use of a syndrome is also the reporting model used for exceptions taken to Hyp mode when they are taken to EL2 using AArch32.

[Figure D1-2](#) shows the general format of the `ESR_ELx` registers.

Figure D1-2 Overall format of the `ESR_ELx` registers

The `ESR_ELx` fields are:

- EC, bits[31:26]** The Exception class field, that indicates the cause of the exception.
- IL, bit[25]** The Instruction length bit, for synchronous exceptions, that indicates whether a trapped instruction was a 16-bit or a 32-bit instruction.
- ISS, bits[24:0]** The Instruction specific syndrome field. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

[ESR_ELx, Exception Syndrome Register \(ELx\) on page D7-1933](#) describes the register in full, including:

- Listing the valid EC field values.
- Describing the ISS for each Exception class.
- Giving a full description of the use of the IL field.

Table D1-8 shows the encoding of the `ESR_ELx.EC` field, the Exception class field. For each EC value, the table references a subsection of the `ESR_ELx` register definition that describes the ISS format, with links to descriptions of possible causes of the exception, for example the configuration required to enable a trap.

Table D1-8 ESR_ELx.EC field encoding

| EC | Exception class | From, state | | To, Exception level | | | ISS encoding description |
|--------|--|-------------|---------|---------------------|------------------|------------------|---|
| | | AArch32 | AArch64 | EL1 | EL2 | EL3 | |
| 000000 | Unknown reason | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for exceptions with an unknown reason on page D7-1938</i> |
| 000001 | Trapped WFI or WFE instruction execution ^a | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from a WFI or WFE instruction on page D7-1939</i> |
| 000011 | Trapped MCR or MRC access with $(\text{coproc} == 0b1111)$ ^a that is not reported using EC 0b000000 | Yes | No | Yes | Yes | Yes ^b | <i>ISS encoding for an exception from an MCR or MRC access on page D7-1940</i> |
| 000100 | Trapped MCRR or MRRC access with $(\text{coproc} == 0b1111)$ ^a that is not reported using EC 0b000000 | Yes | No | Yes | Yes | Yes ^c | <i>ISS encoding for an exception from an MCRR or MRRC access on page D7-1943</i> |
| 000101 | Trapped MCR or MRC access with $(\text{coproc} == 0b1110)$ ^a | Yes | No | Yes | Yes | Yes | <i>ISS encoding for an exception from an MCR or MRC access on page D7-1940</i> |
| 000110 | Trapped LDC or STC access ^a | Yes | No | Yes | Yes | Yes | <i>ISS encoding for an exception from an LDC or STC instruction on page D7-1945</i> |
| 000111 | Access to Advanced SIMD or floating-point functionality trapped by <code>CPACR_EL1.FPEN</code> or <code>CPTR_ELx.TFP</code> control ^d | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from <code>CPACR_EL1.FPEN</code> or <code>CPTR_ELx.TFP</code> on page D7-1947</i> |
| 001000 | Trapped VMRS access, from ID group traps, that is not reported using EC 0b000111 ^e | Yes | No | No | Yes | No | <i>ISS encoding for an exception from an MCR or MRC access on page D7-1940</i> |
| 001100 | Trapped MRRC access with $(\text{coproc} == 0b1110)$ ^a | Yes | No | Yes | Yes | Yes | <i>ISS encoding for an exception from an MCRR or MRRC access on page D7-1943</i> |
| 001110 | Illegal Execution state | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D7-1948</i> |
| 010001 | SVC instruction execution in AArch32 state | Yes | No | Yes | Yes ^f | No | <i>ISS encoding for an exception from HVC or SVC instruction execution on page D7-1948</i> |
| 010010 | HVC instruction execution in AArch32 state, when HVC is not disabled | Yes | No | No | Yes | No | |
| 010011 | SMC instruction execution in AArch32 state, when SMC is not disabled | Yes | No | No | Yes ^g | Yes | <i>ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-1949</i> |

Table D1-8 **ESR_ELx.EC** field encoding (continued)

| EC | Exception class | From, state | | To, Exception level | | | ISS encoding description |
|--------|--|-------------|---------|---------------------|------------------|-----|--|
| | | AArch32 | AArch64 | EL1 | EL2 | EL3 | |
| 010101 | SVC instruction execution in AArch64 state | No | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from HVC or SVC instruction execution on page D7-1948</i> |
| 010110 | HVC instruction execution in AArch64 state, when HVC is not disabled | No | Yes | No | Yes | Yes | |
| 010111 | SMC instruction execution in AArch64 state, when SMC is not disabled | No | Yes | No | Yes ^g | Yes | <i>ISS encoding for an exception from SMC instruction execution in AArch64 state on page D7-1951</i> |
| 011000 | Trapped MSR, MRS, or System instruction execution, that is not reported using EC 0x00, 0x01, or 0x07 | No | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state on page D7-1951</i> |
| 011111 | IMPLEMENTATION DEFINED exception taken to EL3 | Yes | Yes | No | No | Yes | <i>ISS encoding for a IMPLEMENTATION DEFINED exception to EL3 on page D7-1953</i> |
| 100000 | Instruction Abort from a lower Exception level ^h | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from an Instruction Abort on page D7-1953</i> |
| 100001 | Instruction Abort taken without a change in Exception level ^h | Yes | Yes | Yes | Yes | Yes | |
| 100010 | PC alignment fault | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D7-1948</i> |
| 100100 | Data Abort from a lower Exception level ⁱ | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from a Data Abort on page D7-1955</i> |
| 100101 | Data Abort taken without a change in Exception level ⁱ | Yes | Yes | Yes | Yes | Yes | |
| 100110 | SP alignment fault | No | Yes | Yes | Yes | Yes | <i>ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault on page D7-1948</i> |
| 101000 | Trapped floating-point exception taken from AArch32 state | Yes | No | Yes | Yes | No | <i>ISS encoding for an exception from a trapped floating-point exception on page D7-1959</i> |
| 101100 | Trapped floating-point exception taken from AArch64 state | No | Yes | Yes | Yes | Yes | |
| 101111 | SError interrupt | Yes | Yes | Yes | Yes | Yes | <i>ISS encoding for an SError interrupt on page D7-1961</i> |

Table D1-8 ESR_ELx.EC field encoding (continued)

| EC | Exception class | From, state | | To, Exception level | | | ISS encoding description |
|--------|---|-------------|---------|---------------------|------------------|------------------|--|
| | | AArch32 | AArch64 | EL1 | EL2 | EL3 | |
| 110000 | Breakpoint exception from a lower Exception level | Yes | Yes | Yes | Yes ^j | No | <i>ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D7-1961</i> |
| 110001 | Breakpoint exception taken without a change in Exception level | Yes | Yes | Yes | Yes ^j | No | |
| 110010 | Software Step exception from a lower Exception level | Yes | Yes | Yes | Yes ^j | No | <i>ISS encoding for an exception from a Software Step exception on page D7-1962</i> |
| 110011 | Software Step exception taken without a change in Exception level | Yes | Yes | Yes | Yes ^j | No | |
| 110100 | Watchpoint exception from a lower Exception level | Yes | Yes | Yes | Yes ^j | No | <i>ISS encoding for an exception from a Watchpoint exception on page D7-1963</i> |
| 110101 | Watchpoint exception taken without a change in Exception level | Yes | Yes | Yes | Yes ^j | No | |
| 111000 | BKPT instruction execution in AArch32 state | Yes | No | Yes | Yes ^j | No | <i>ISS encoding for an exception from execution of a Breakpoint instruction on page D7-1963</i> |
| 111010 | Vector Catch exception from AArch32 state | Yes | No | No | Yes ^j | No | <i>ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D7-1961</i> |
| 111100 | BRK instruction execution in AArch64 state | No | Yes | Yes | Yes ^j | Yes ^k | <i>ISS encoding for an exception from execution of a Breakpoint instruction on page D7-1963</i> |

- a. Exceptions caused by configurable traps, enables, or disables.
- b. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1590.
- c. Only for MRRR or MRRC accesses to the PMCCNTR_EL0 or PMCCNTR.
- d. Excludes exceptions that are generated because the value of HCR_EL2.TGE is 1.
- e. Applies only to traps of accesses to MVFR0, MVFR1, MVFR2, or FPSID. Includes traps of VMRS accesses. Because the MVFR_n registers are read-only and a VMSR access to the FPSID is ignored and not trapped, there are no MCR or VMSR accesses that can be trapped with this EC value.
- f. Only as a result of HCR_EL2.TGE.
- g. Only as a result of HCR_EL2.TSC.
- h. Used for MMU faults generated by instruction accesses, and for synchronous external aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- i. Used for MMU faults generated by data accesses, Alignment faults other than SP alignment faults and PC alignment faults, and for synchronous external aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.
- j. Only as a result of HCR_EL2.TGE == 1 or MDCR_EL2.TDE == 1.
- k. Only if the BRK instruction is executed in EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.

Reserved EC values

For EC values not shown in [Table D1-8 on page D1-1524](#):

- Unused EC values in the range 0b000000-0b101100 (0x00-0x2C) are reserved by ARM for future use for synchronous exceptions.
- Unused EC values in the range 0b101101-0b111111 (0x2D-0x3F) are reserved by ARM for future use, and might be used for synchronous or asynchronous exceptions.

Exceptions with an unknown reason

These are the exceptions reported with an **ESR_ELx**.EC value of 0b000000

This encoding reports an exception with an unknown reason.

When **ESR_ELx**.EC returns a value of 0x00, all other fields of **ESR_ELx** are invalid, and defined as follows:

- IL is set to 1.
- ISS[24:0] is RES0.

An exception with an unknown reason occurs for the following reasons:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
 - Instruction encodings for instructions that are not implemented.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- An exception generated by any of the **SCTLR_EL1**.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by **HCR_EL2**.HCD or **SCR_EL3**.HCE.
 - An SMC instruction when disabled by **SCR_EL3**.SMD.
 - An HLT instruction when disabled by **EDSCR**.HDE.
- Attempted execution of an MSR or MRS to **SP_EL0** when the value of **SPSel.SP** is 0.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction in Non-secure state from EL0 when the value of **HCR_EL2**.TGE is 1.
 - A DCPS2 instruction from EL1 or EL0 when the value of **SCR_EL3**.NS is 0, or when EL2 is not implemented.
 - A DCPS3 instruction when the value of **EDSCR**.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution of an SRS instruction using R13_mon from Secure EL1. See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590](#).
- In Debug state when the value of **EDSCR**.SDD is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to **SPSR_mon**, **SP_mon**, or **LR_mon**.

- An exception that is taken to EL2 because the value of [HCR_EL2.TGE](#) is 1 that, if the value of [HCR_EL2.TGE](#) was 0 would have been reported with an [ESR_ELx.EC](#) value of 0x07.

Exception from a WFI or WFE instruction, from AArch32 or AArch64 state

This is the exception syndrome with EC value 0b000001.

This reports exceptions from WFI or WFE instructions executed in either Execution state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the trapped instruction was a WFI or a WFE. [ISS encoding for an exception from a WFI or WFE instruction on page D7-1939](#) describes the format of this syndrome.

The following sections describe configuration settings for generating these exceptions:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1565.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1581.](#)
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590.](#)

Exception from an MCR or MRC access from AArch32 state

These are the exception syndromes with the following EC values:

- 0b000011, MCR or MCR access to a System register in the (coproc==0b1111) encoding space.
- 0b000101, MCR or MCR access to a System register in the (coproc==0b1110) encoding space.
- 0b001000, VMRS System register access.

These report exceptions from MRC, MCR, or VMRS instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0b000000.

The returned syndrome indicates whether the instruction was an MRC or an MCR, and the instruction arguments. [ISS encoding for an exception from an MCR or MRC access on page D7-1940](#) describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1569.](#)
- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1570.](#)
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1573.](#)
- [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1574.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1575.](#)
- [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1576.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1577.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578.](#)
- [Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1582.](#)
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1584.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1587.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1588.](#)
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590.](#)
- [Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1593.](#)

- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1597.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1567.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1568.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578, for trapped accesses to the JIDR.](#)
- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1583.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1585.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1586.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1586.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1595.](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1596.](#)

[Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578](#) describes configuration settings for generating exceptions that are reported using EC value 0b001000.

Exception from an MCRR or MRRC access from AArch32 state

These are the exception syndromes with the following EC values:

- 0b000100, MRRC or MCRR access to a System register in the (coproc==0b1111) encoding space.
- 0b001100, MRRC access to a System register in the (coproc==0b1110) encoding space.

These report exceptions from MCRR or MRRC instructions executed in AArch32 state that result from configurable traps, enables, or disables and are not reported using the EC code of 0x00.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. [ISS encoding for an exception from an MCRR or MRRC access on page D7-1943](#) describes the format of this syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1569.](#)
- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1570.](#)
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1573.](#)
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1584.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1587.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1588.](#)
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1597.](#)

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1567.](#)
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1568.](#)
- [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1583.](#)
- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1585.](#)

- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1595.](#)

Exception from an LDC or STC access to a System register

This is the exception syndrome with EC value 0b000110.

This reports exceptions from LDC or STC instructions executed in AArch32 state that result from configurable traps, enables, or disables.

The returned syndrome indicates whether the instruction was an MCRR or an MRRC, and the instruction arguments. [ISS encoding for an exception from an LDC or STC instruction on page D7-1945](#) describes the format of this syndrome.

———— **Note** ————

The only architected uses of these instructions are:

- An STC to write to memory from [DBGDTRRXint](#).
- An LDC to read from memory to [DBGDTRTXint](#).

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000110:

- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1568.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1586](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1596.](#)

Exception from an access to an Advanced SIMD or floating-point register, from either Execution state, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP

This is the exception syndrome with EC value 0b000111.

———— **Note** ————

If [HCR_EL2.TGE](#) is 1, these exceptions are reported with EC value 0b000000 instead of 0b000111. [Reporting the EC encoding when an exception is routed to EL2 on page D1-1535](#) describes this.

It reports exceptions from accesses to the Advanced SIMD and floating-point register bank, or to SIMD and floating-point System registers, when [CPACR_EL1.FPEN](#) != 0b11 or [CPTR_ELx.TFP](#) == 1.

These are taken from either Execution state.

[ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP on page D7-1947](#) describes the format of the returned syndrome.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000111:

- [Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1568.](#)
- [General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1583](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)

Exception from an Illegal Execution state, PC alignment fault, or SP alignment fault

These are the exception syndromes with the following EC values:

- 0b001110, Illegal Execution state.
- 0b100010, PC alignment fault.
- 0b100110, SP alignment fault.

When [ESR_ELx.EC](#) returns one of these values, the ISS field does not return any syndrome information and the ISS field is RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. See [The Illegal Execution state exception on page D1-1539](#) and [PC alignment checking on page D1-1515](#). [SP alignment checking on page D1-1515](#) describes the configuration settings for generating SP alignment fault exceptions.

Exception from HVC or SVC instruction execution

These are the exception syndromes with the following EC values:

- 0b010001, SVC instruction executed in AArch32 state.
- 0b010010, HVC instruction executed, when not disabled, in AArch32 state.
- 0b010101, SVC instruction executed in AArch64 state.
- 0b010110, HVC instruction executed, when not disabled, in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. [ISS encoding for an exception from HVC or SVC instruction execution on page D7-1948](#) describes the format of this syndrome.

———— **Note** —————

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not include conditionality information.

See [System calls on page D1-1598](#).

Exception from SMC instruction execution in AArch32 state

This is the exception syndrome with EC value 0b010011.

This reports the exception from an SMC that is not disabled and is executed in AArch32 state.

[ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-1949](#) describes the format of this syndrome.

———— **Note** —————

[ISS encoding for an exception from SMC instruction execution in AArch32 state on page D7-1949](#) describes ISS[24:0] for each of the following cases:

- When an SMC instruction completes normally and generates an exception that is taken to EL3.
- When an SMC instruction is trapped to EL2 from Non-secure EL1 because [HCR_EL2.TSC](#) is set to 1.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578](#) describes the configuration settings for trapping SMC instructions to EL2.

Exception from SMC instruction execution in AArch64 state

This is the exception syndrome with EC value 0b010111.

This reports the exception from an SMC that is not disabled and is executed in AArch64 state.

The returned syndrome indicates the immediate value given as an instruction argument. [ISS encoding for an exception from SMC instruction execution in AArch64 state on page D7-1951](#) describes the format of this syndrome.

———— **Note** —————

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578](#) describes the configuration settings for trapping SMC instructions to EL2.

Exception from MSR, MRS, or System instruction execution in AArch64 state

This is the exception syndrome with the EC value 0b011000.

These report exceptions from MSR, MRS, or System instructions executed in AArch64 state that result from configurable traps, enables, or disables and are not reported using the EC codes of 0b000000, 0b000001, or 0b000111.

———— **Note** —————

[The System instruction class encoding space on page C5-270](#) identifies the System instructions referred to in this description.

The returned syndrome indicates whether the instruction was an MSR or an MRS, and the instruction arguments. [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state on page D7-1951](#) describes the format of this syndrome.

For exceptions caused by System instructions, see [System on page C4-199](#) for the instruction arguments returned in the syndrome.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- In [EL1 configurable controls on page D1-1563](#):
 - [Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1564](#).
 - [Traps to EL1 of EL0 accesses to the CTR_EL0 on page D1-1565](#).
 - [Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1566](#).
 - [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1566](#).
 - [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers on page D1-1567](#).
 - [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1568](#).
 - [Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1569](#).
 - [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1570](#).
- In [EL2 configurable controls on page D1-1571](#):
 - [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1573](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1574](#).
 - [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1574](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1575](#).
 - [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1576](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1577](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578](#).
 - [Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1582](#).
 - [Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1583](#).
 - [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1585](#).
 - [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1586](#).
 - [Trapping general System register accesses to debug registers to EL2 on page D1-1586](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1587](#).
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1588](#).

- In *EL3 configurable controls* on page D1-1589:
 - *Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers* on page D1-1592.
 - *Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR* on page D1-1593.
 - *Traps to EL3 of all System register accesses to the trace registers* on page D1-1594.
 - *Trapping System register accesses to powerdown debug registers to EL3* on page D1-1595.
 - *Trapping general System register accesses to debug registers to EL3* on page D1-1596.
 - *Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers* on page D1-1597.

Exception from an Instruction abort

These are the exception syndromes with the following EC values:

- 0100000, for an Instruction abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100001, for an Instruction abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for MMU faults and synchronous external aborts, including synchronous parity or ECC errors, that are generated by instruction accesses. They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from an Instruction Abort* on page D7-1953 describes the format of this syndrome.

Exception from a Data abort

These are the exception syndromes with the following EC values:

- 0b100100, for a Data abort exception taken from a lower Exception level, that could be using AArch64 or AArch32.
- 0b100101, for a Data abort exception taken without a change in Exception level, meaning it is taken from an Exception level that is using AArch64.

These EC values are used for the following exceptions if the exception is generated by a data access:

- MMU faults.
- Alignment faults other than SP alignment faults and PC alignment faults.
- Synchronous external aborts, including synchronous parity or ECC errors.

They are not used for Debug exceptions.

The returned syndrome provides more information about the exception, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Data Abort* on page D7-1955 describes the format of this syndrome.

Floating-point exceptions

These are the exception syndromes with the following EC values:

- 0b101000, trapped floating-point exception from AArch32.
- 0b101100, trapped floating-point exception from AArch64.

These Exception classes are supported only when the SIMD and floating-point implementation supports the trapping of floating-point exceptions. Otherwise, the 0x28 and 0x2C EC values are reserved. That is, these EC values are used to report the floating-point exceptions defined by IEEE 754, and input denormal.

The returned syndrome identifies the trapped floating-point exception or exceptions. *ISS encoding for an exception from a trapped floating-point exception* on page D7-1959 describes the format of this syndrome.

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

SError interrupt

This is the exception syndrome with EC value 0b101111.

It is used to report the exception caused by an SError interrupt.

The returned syndrome is implementation specific. *ISS encoding for an SError interrupt on page D7-1961* describes the format of this syndrome. See also *Asynchronous exception types, routing, masking and priorities on page D1-1555*.

Breakpoint exception or Vector Catch exception

These are the exception syndromes with the following EC values:

- 0b110000, Breakpoint exception taken from a lower Exception level.
- 0b110001, Breakpoint exception taken without a change of Exception level.
- 0b111010, AArch32 Vector Catch exception.

The returned syndrome provides a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Breakpoint or Vector Catch debug exception on page D7-1961* describes the format of this syndrome.

For more information about generating these exceptions, see:

- *Breakpoint exceptions on page D2-1641*.
- *Vector Catch exceptions on page D2-1672*.

Watchpoint exception

These are the exception syndromes with the following EC values:

- 0b110100, Watchpoint exception taken from a lower Exception level.
- 0b110101, Watchpoint exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Watchpoint exception on page D7-1963* describes the format of this syndrome.

For more information about generating these exceptions, see *Watchpoint exceptions on page D2-1657*.

Software Step exception

These are the exception syndromes with the following EC values:

- 0b110010, Software Step exception taken from a lower Exception level.
- 0b110011, Software Step exception taken without a change of Exception level.

The returned syndrome provides more information about the watchpoint, including a fault code that indicates the cause of the exception. *ISS encoding for an exception from a Software Step exception on page D7-1962* describes the format of this syndrome.

For more information about generating these exceptions, see *Software Step exceptions on page D2-1673*.

Breakpoint Instruction exception

These are the exception syndromes with the following EC values:

- 0b111000, BKPT instruction executed in AArch32 state.
- 0b111100, BRK instruction executed in AArch64 state.

The returned syndrome provides the comment that was provided as an argument to the Breakpoint Instruction. *ISS encoding for an exception from execution of a Breakpoint instruction on page D7-1963* describes the format of this syndrome.

For more information about generating these exceptions, see *Breakpoint Instruction exceptions on page D2-1639*.

Reporting the EC encoding when an exception is routed to EL2

When an exception is taken to EL2 because the exception routing control `HCR_EL2.TGE` is enabled, the EC encoding that would have been used if the exception had been taken to EL1 is recorded in `ESR_EL2.EC` instead, unless the encoding is `0x07`.

Exceptions that use `0x07` when the `HCR_EL2.TGE` routing control is disabled use `0x00` when the `HCR_EL2.TGE` routing control is enabled.

D1.10.5 Summary of register updates on faults taken to an Exception level that is using AArch64

For all exceptions taken to an Exception level using AArch64 that are not listed in *Validity of FAR_ELx*, the `FAR_ELx` for the Exception level the exception is taken to is UNKNOWN.

For all exceptions taken to EL2 using AArch64 that are not listed in *Validity of HPFAR_EL2*, the `HPFAR_EL2` is UNKNOWN.

Validity of FAR_ELx

The faulting virtual address is saved in `FAR_ELx` for the Exception level the exception is taken to if an exception is one of:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

The architecture permits that the `FAR_ELx` is UNKNOWN for Synchronous External Aborts other than Synchronous External Aborts on Translation Table Walks. In this case, the `ISS.FnV` bit returned in `ESR_ELx` indicates whether `FAR_ELx` is valid.

If an exception is taken from an Exception level using AArch32 into an Exception level using AArch64, and that exception writes the `FAR_ELx` at the Exception level the exception is taken to, the most significant 32 bits of the `FAR_ELx` are all zero, unless both:

- The faulting address was generated by a load or store that sequentially incremented from address `0xFFFFFFFF`. Such a load or store instruction is `CONSTRAINED UNPREDICTABLE`, see *Out of range virtual address on page K1-5464*.
- The implementation treats such incrementing as setting bit[32] of the virtual address.

The `FAR_ELx` for an Exception level is made UNKNOWN as a result of an exception return from that Exception level.

Validity of HPFAR_EL2

The faulting IPA is saved in `HPFAR_EL2` if the exception is an Instruction Abort or Data Abort taken to EL2 and the fault is one of:

- A Translation or Access Flag fault on a stage 2 translation.
- A stage 2 Address Size fault.
- A fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.

`HPFAR_EL2` is made UNKNOWN as a result of an exception return from EL2.

D1.11 Exception return

In the ARMv8-A architecture, an exception return is always to the same Exception level or a lower Exception level. An exception return is used for:

- A return to a previously executing thread.
- Entry to a new execution thread. For example:
 - The initialization of a hypervisor by a Secure monitor.
 - The initialization of an operating system by a hypervisor.
 - Application entry from an operating system or hypervisor.

An exception return requires the simultaneous restoration of the PC and `PSTATE` to values that are consistent with the desired state of execution on returning from the exception.

In AArch64 state, an ERET instruction causes an exception return. On an ERET instruction:

- The PC is restored with the value held in the `ELR_ELx`.
- `PSTATE` is restored by using the contents of the `SPSR_ELx`.

The `ELR_ELx` and `SPSR_ELx` are the `ELR_ELx` and `SPSR_ELx` at the Exception level the exception is returning from. The exception return makes this `ELR_ELx` and `SPSR_ELx` UNKNOWN.

See *Address tagging in AArch64 state on page D4-1724* for details of how tagged addresses are handled in an Exception return from an Exception level using AArch64 to an Exception level using AArch64.

———— **Note** —————

When returning from an Exception level using AArch64 to an Exception level using AArch32, the top 32 bits of the `ELR_ELx` are ignored.

An ERET instruction also:

- Sets the Event Register for the PE executing the ERET instruction. See *Mechanisms for entering a low-power state on page D1-1599*.
- Resets the local exclusive monitor for the PE executing the ERET instruction. This removes the risk of errors that might be caused when a path to an exception return fails to include a CLREX instruction.

———— **Note** —————

This behavior prevents self-hosted debug from software stepping through an LDREX/STREX pair. However, when self-hosted debug is using software step, it is highly probable that the exclusive monitor state would be lost anyway, for other reasons. *Stepping code that uses exclusive monitors on page D2-1685* describes this.

It is IMPLEMENTATION DEFINED whether the resetting of the local exclusive monitor also resets the global exclusive monitor.

The ERET instruction is UNDEFINED in EL0.

When returning from an Exception level using AArch64 to an Exception level using AArch32, the AArch32 context is restored. The ARMv8-A architecture defines the relationship between AArch64 state and AArch32 state, for:

- General-purpose registers.
- Special-purpose registers.
- System registers.

In an implementation that includes EL3, the Security state can only change on returning from an exception if the return is from EL3 to a lower Exception level.

The following sections give more information:

- [Exception return and PC alignment.](#)
- [Illegal return events from AArch64 state.](#)
- [Legal returns that set PSTATE.IL to 1 on page D1-1539.](#)
- [The Illegal Execution state exception on page D1-1539.](#)
- [Pseudocode description of exception return on page D1-1539.](#)

D1.11.1 Exception return and PC alignment

When `SPSR_ELx.M[4] == 0`, indicating an Exception return to AArch64 state, the value of `ELR_ELx` is transferred to the PC. If this value is misaligned, subsequent execution results in a PC alignment fault exception.

When `SPSR_ELx.M[4] == 1`, indicating an Exception return to AArch32 state, the value of `ELR_ELx` is transferred to the PC except that, for a legal exception return:

- If `SPSR_ELx.T` is 0, `ELR_ELx[1:0]` are treated as being 0 for restoring the PC.
- If `SPSR_ELx.T` is 1, `ELR_ELx[0]` is treated as being 0 for restoring the PC.

This means that a PC alignment fault exception cannot occur following a legal exception return from AArch64 state to AArch32 state. However, where the Exception return with `SPSR_ELx.M[4] == 1` is an illegal exception return then it is IMPLEMENTATION DEFINED whether a misaligned value in `ELR_ELx` is aligned when it is restored to the PC.

———— **Note** ————

In an implementation that forces the alignment of the PC value restored from `SPSR_ELx` on an illegal exception return with `SPSR_ELx.M[4] == 1`, if `SPSR_ELx.T == 1` the restored PC value might give rise to a PC alignment fault exception, because the PE remains in AArch64 state and only `ELR_ELx[0]` is treated as being 0 for restoring the PC.

For more information about the illegal exception return cases see [Illegal return events from AArch64 state](#).

D1.11.2 Illegal return events from AArch64 state

In this section:

Return In AArch64 state, refers to any of:

- Execution of an ERET instruction.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

Saved process state value In AArch64 state, refers to any of:

- The value held in the `SPSR_ELx` for an ERET instruction.
- The value held in the `SPSR_ELx` for a DRPS instruction executed in Debug state.
- The value held in the `DSPSR_ELO` for a Debug state exit.

Link address In AArch64 state, refers to any of:

- The address held in `ELR_ELx` for an ERET instruction.
- The address held in `DLR_ELO` for a Debug state exit.

Configured from reset Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling returns to a mode or state that is illegal. In AArch64 state, this can occur as the result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the Exception level being returned to is not implemented. For example a return to EL2 when EL2 is not implemented.

- A return to EL2 when EL3 is implemented and the value of the [SCR_EL3.NS](#) bit is 0.
- A return to Non-secure EL1 when EL2 is implemented and the value of the [HCR_EL2.TGE](#) bit is 1.
- A return where the value of the saved process state M[4] bit is 0, indicating a return to AArch64 state, and one of the following is true:
 - The M[1] bit is 1.
 - The M[3:0] bits are 0b0001.
 - The Exception level being returned to is using AArch32 state, as programmed by the [SCR_EL3.RW](#) or [HCR_EL2.RW](#) bits, or as configured from reset.
- A return where the value of the saved process state M[4] bit is 1, indicating a return to AArch32 state, and one of the following is true:
 - The M field value is not a valid AArch32 state PE mode. [Table D1-4 on page D1-1511](#) shows the valid M[3:0] values for AArch32 state PE modes. This includes the case where M[3:0] is 0b0000, indicating User mode, and EL0 does not support AArch32 state.
 - The Exception level being returned to is using AArch64 state as determined by the [SCR_EL3.RW](#) or [HCR_EL2.RW](#) field or the configuration from reset. This includes the case where the Exception level being returned to does not support AArch32 state.

———— **Note** —————

This means that, in an implementation that supports only AArch64 state, any attempt to return to AArch32 state is an illegal exception return.

- A Debug state exit from EL0 using AArch64 state, to EL0 using AArch32 state.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal return.
- [PSTATE.{EL, nRW, SP}](#) are unchanged. This means the Exception level, Execution state, and stack pointer selection do not change as a result of the return.
- The following [PSTATE](#) bits are restored from the saved process state value:
 - The N, Z, C, V Condition flags.
 - The D, A, I, F exception mask bits.
- If the illegal return is an illegal exception return, the [PSTATE.SS](#) bit is handled as normal for a return. That is, the SS bit is handled in the same way as an exception return that is not an illegal exception return. See [Software Step exceptions on page D2-1673](#).

In all these cases the [PSTATE.SS](#) bit is handled as it would be for a normal return, as described in [Entering the active-not-pending state on page D2-1675](#) and [Exiting Debug state on page H2-4880](#). DRPS never sets the SS bit. This is indicated in [Entering the active-not-pending state on page D2-1675](#).

- If the illegal return is not a DRPS instruction executed in Debug state, the PC is restored from the link address. However, if the value of the M[4] bit of the saved process state is 1, indicating a return to AArch32 state, then:
 - It is IMPLEMENTATION DEFINED whether the PC value is aligned by setting the bottom 1 or 2 bits of its value to 0, as determined by the T bit of the saved process state. See [Exception return and PC alignment on page D1-1537](#).
 - It is CONSTRAINED UNPREDICTABLE whether bits[63:32] of the PC are all set to zero, or are set to the value of the corresponding bits of the link address.

The implementation determines the choice of these two options, and the choice might vary dynamically. Therefore, software must tolerate both of these options.

[Relaxation of the tagged address handling requirements on an Illegal exception return on page D4-1725](#) describes how tagged addresses are handled in an Illegal Exception return from an Exception level using AArch64 to an Exception level using AArch64.

When the value of the `PSTATE.IL` bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#).

All aspects of the illegal return, other than the effects described in this section, occur as they do for a legal return.

D1.11.3 Legal returns that set `PSTATE.IL` to 1

In this section, *return*, *saved process state value*, and *link address* have the same meaning as defined in [Illegal return events from AArch64 state on page D1-1537](#).

If the value of the `IL` bit in the saved process state is 1, then it is copied to `PSTATE` by a return, meaning that `PSTATE.IL` is set to 1. In this case, if the return is not an illegal return, and targets AArch32 state, then the `PSTATE.{IT, T}` bits are either:

- Set to 0.
- Copied from the saved process state value.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

The `PSTATE.{IT, T}` bits are only valid in AArch32 state, see [Process state, PSTATE on page G1-3805](#).

When the `PSTATE.IL` bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See [The Illegal Execution state exception](#).

D1.11.4 The Illegal Execution state exception

When the value of the `PSTATE.IL` bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. In AArch64 state, the `PSTATE.IL` bit can be set to 1 by any of:

- An illegal return, as described in [Illegal return events from AArch64 state on page D1-1537](#).
- A legal return that sets `PSTATE.IL` to 1, as described in [Legal returns that set PSTATE.IL to 1](#).

An Illegal Execution state exception sets `ESR_ELx.EC` for the target Exception level to the value of `0x0E`.

On taking any exception to an Exception level that is using AArch64 state:

1. The value of the `PSTATE.IL` bit is copied into the `SPSR_ELx.IL` bit for the Exception level to which the exception is taken.
2. The `PSTATE.IL` bit is cleared to 0.

———— **Note** —————

This means that it is not possible for software to observe the value of `PSTATE.IL`.

For the priority of this exception class, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#).

D1.11.5 Pseudocode description of exception return

The `AArch64.ExceptionReturn()` pseudocode function transfers the return address to the PC, and restores `PSTATE` to its saved value by calling `SetPSTATEFromPSR()`.

The `IllegalExceptionReturn()` function checks for an Illegal Execution state exception.

D1.12 The Exception level hierarchy

The System registers provide controls that control PE behavior through the Exception level hierarchy.

If EL3 and EL2 are implemented, System registers at EL3 and EL2 provide controls that control the Execution state of lower Exception levels.

Table D1-9 shows the principal System registers.

Table D1-9 Principal System registers

| EL3 | EL2 | EL1 | Notes |
|---------------------------|---------------------------|---------------------------|--|
| SCTLR_EL3 | SCTLR_EL2 | SCTLR_EL1 | Controls execution for its own Exception level. |
| SCR_EL3 | HCR_EL2 | - | Controls execution at lower Exception levels. |
| - | HSTR_EL2 | - | Used only if at least one of EL1 and EL0 is using AArch32. |

The prioritization of exceptions generated as a result of controls in these registers is described in *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548.

The following sections describe the Exception level hierarchy:

- *The hierarchy of configuration and routing control.*
- *Control of SIMD, floating-point and trace functionality* on page D1-1546.
- *Control of IMPLEMENTATION DEFINED features* on page D1-1546.
- *Routing exceptions to EL2* on page D1-1548.

D1.12.1 The hierarchy of configuration and routing control

The following subsections give a summary of the controls available at each Exception level for controlling execution at that Exception level and all lower Exception levels:

- *Controls provided at EL3.*
- *Controls provided at EL2* on page D1-1542.
- *Controls provided at EL1* on page D1-1544.

For information on how the controls summarized in these subsections affect PE behavior, see the definitions of the control bits in the register descriptions.

Controls provided at EL3

See:

- *Controls provided by the [SCR_EL3](#).*
- *Controls provided by the [SCTLR_EL3](#)* on page D1-1541.
- *Controls provided by the [MDCR_EL3](#)* on page D1-1541.

Controls provided by the [SCR_EL3](#)

[SCR_EL3.NS](#) Determines the Security state of execution at EL1 and EL0.

[SCR_EL3.RW](#) Determines the Execution state of the next-lower Exception level.

[SCR_EL3](#).{EA, FIQ, IRQ}

Route:

EA Physical SError interrupts and synchronous External Aborts to EL3.

FIQ Physical FIQ interrupts to EL3.

IRQ Physical IRQ interrupts to EL3.

[SCR_EL3.SMD](#) Disables the Secure Monitor Call exception.

| | |
|-----------------------------|--|
| SCR_EL3.HCE | Enables the Hypervisor Call exception. |
| SCR_EL3.ST | Enables Secure EL1 access to the Secure timer. |
| SCR_EL3.SIF | Secure Instruction Fetch. When in Secure state, disables instruction fetches from Non-secure memory. |
| SCR_EL3.TWI | Trap Wait-For-Interrupt. |
| SCR_EL3.TWE | Trap Wait-For-Event. |

Controls provided by the [SCTLR_EL3](#)

[SCTLR_EL3](#).{A, SA} Enable alignment checking:

| | |
|-----------|-----------------------------------|
| A | On data accesses from EL3. |
| SA | On the SP, when executing at EL3. |

[SCTLR_EL3](#).{M, C, I, WXN}

Memory system control bits:

| | |
|------------|--|
| M | Enables EL3 stage 1 address translation. |
| C | When set to 0, makes data accesses to Normal memory from EL3, and Normal memory accesses to the EL3 translation tables, Non-cacheable. |
| I | When set to 0, makes instruction accesses to Normal memory from EL3 Non-cacheable. |
| WXN | For accesses from EL3, enables treating all writable memory regions as XN, execute never. |

[SCTLR_EL3.EE](#) Defines the endianness of data accesses from EL3, including stage 1 translation table walks at EL3.

———— **Note** —————

Instruction fetches are always little-endian.

Controls provided by the [MDCR_EL3](#)

[MDCR_EL3](#).{EPMAD, EDAD}

Enable external debugger accesses to:

| | |
|--------------|--------------------------------------|
| EPMAD | Performance Monitors registers. |
| EDAD | Breakpoint and Watchpoint registers. |

[MDCR_EL3](#).{SPME, SDD, SPD32}

Secure debug controls:

| | |
|--------------|---|
| SPME | Secure Performance Monitors enable. Enables event counting in Secure state. |
| SDD | Disables all debug exceptions taken from Secure state, if the <i>debug target Exception level</i> , EL _D , is using AArch64. |
| SPD32 | Enables debug exceptions from Secure EL1 using AArch32. |

[MDCR_EL3](#).{TDOSA, TDA, TPM}

These are trap controls, that control traps to EL3 of EL2, EL1, and EL0 accesses to the following:

| | |
|--------------|---|
| TDOSA | The OS-related debug registers. |
| TDA | Those debug registers not included in the MDCR_EL3 .TDOSA trap. |
| TPM | The Performance Monitors registers. |

For EL1 and EL0, these traps apply to accesses from both Security states.

Controls provided at EL2

EL2 is implemented only in Non-secure state, and its controls apply only to execution in Non-secure EL2, Non-secure EL1, and Non-secure EL0. See:

- [Controls provided by SCTLR_EL2.](#)
- [Controls provided by HCR_EL2.](#)
- [Controls provided by the HSTR_EL2 on page D1-1544.](#)
- [Controls provided by the MDCR_EL2 on page D1-1544.](#)

Controls provided by SCTLR_EL2

SCTLR_EL2.{A, SA} Enable alignment checking:

| | |
|-----------|-----------------------------------|
| A | On data accesses from EL2. |
| SA | On the SP, when executing at EL2. |

SCTLR_EL2.{M, C, I, WXN}

Memory system control bits:

| | |
|------------|--|
| M | Enables EL2 stage 1 address translation. |
| C | When set to 0, makes data accesses to Normal memory from EL2, and Normal memory accesses to the EL2 translation tables, Non-cacheable. |
| I | When set to 0, makes instruction accesses to Normal memory from EL2 Non-cacheable. |
| WXN | For accesses from EL2, enables treating all writable memory regions as XN, execute never. |

SCTLR_EL2.EE Defines the endianness of data accesses from EL2, including stage 1 translation table walks at EL2.

Also defines the endianness of stage 2 translation table walks at Non-secure EL1 and EL0.

———— **Note** —————

Instruction fetches are always little-endian.

Controls provided by HCR_EL2

HCR_EL2.RW Determines the Execution state of the next-lower Exception level.

HCR_EL2.{AMO, IMO, FMO}

Route physical interrupts to EL2, and if the value of **HCR_EL2.TGE** is 0, enable virtual interrupts:

| | |
|------------|--|
| AMO | Route physical SError interrupts to EL2 and enable virtual SError interrupts |
| IMO | Route physical IRQ interrupts to EL2 and enable virtual IRQ interrupts. |
| FMO | Route physical FIQ interrupts to EL2 and enable virtual FIQ interrupts. |

———— **Note** —————

- If a physical interrupt is routed to both EL3 and EL2, routing to EL3 takes precedence over routing to EL2.
- When the value of **HCR_EL2.TGE** is 0, the virtual interrupt enables apply regardless of whether the corresponding physical interrupt is routed to EL2 or to EL3.
- When the value of **HCR_EL2.TGE** is 1 the virtual interrupts are disabled.

HCR_EL2.{VSE, VI, VF}

Cause a virtual interrupt to be pending:

- VSE** Virtual SError interrupt.
- VI** Virtual IRQ interrupt.
- VF** Virtual FIQ interrupt.

HCR_EL2.VM Enable bit for Non-secure EL1&0 stage 2 address translations.

HCR_EL2.{SWIO, PTW, FB, BSU, DC, CD, ID}

Controls for memory system behavior for accesses made from Non-secure EL1 and EL0:

- SWIO** Set/Way Invalidate Override.
- PTW** Protect Table Walk.
- FB** Force broadcast of TLB and instruction cache maintenance instructions.
- BSU** Barrier Shareability Upgrade.
- DC** Default Cacheability control for the EL1&0 translation regime.
- CD** For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translation table walks to Normal memory, and stage 2 translations for data accesses to Normal memory, to be Non-cacheable.
- ID** For the Non-secure EL1&0 translation regime, when set to 1, forces stage 2 translations for instruction accesses to Normal memory be Non-cacheable.

HCR_EL2.HCD Hypervisor Call Disable.

———— **Note** ————

If an implementation includes EL3, this bit is RES0.

HCR_EL2.{TRVM, TDZ, TVM, TTLB, TPU, TPC, TSW, TACR, TIDCP, TSC, TID0, TID1, TID2, TID3, TWE, TWI}

Trap operations performed at Non-secure EL1 or EL0 to EL2, as follows:

- TRVM** Trap Read of Virtual Memory controls.
- TDZ** Trap Data Cache Zero.
- TVM** Trap Virtual Memory controls.
- TTLB** Trap TLB maintenance instructions.
- TPU** Trap cache maintenance to the Point of Unification instructions.
- TPC** Trap data cache maintenance to the Point of Coherency instructions.
- TSW** Trap data cache maintenance by Set/Way instructions.
- TACR** Trap Auxiliary Control Register accesses.
- TIDCP** Trap Implementation-Dependent functionality.
- TSC** Trap Secure Monitor Call.
- TID0** Trap ID Group 0 register accesses.
- TID1** Trap ID Group 1 register accesses.
- TID2** Trap ID Group 2 register accesses.
- TID3** Trap ID Group 3 register accesses.
- TWI** Trap Wait-For-Interrupt.
- TWE** Trap Wait-For-Event.

———— **Note** ————

There are no AArch64 System registers in ID Group 0, therefore the TID0 trap is only relevant when Non-secure EL1 is using AArch32.

HCR_EL2.TGE Trap General Exceptions.

Controls provided by the **HSTR_EL2**

When EL2 is using AArch64 and at least one of Non-secure EL1 or EL0 is using AArch32, **HSTR_EL2** provides the following trap of Non-secure AArch32 operation to EL2:

HSTR_EL2.Tn, for values of *n* in the set {0-3, 5-13, 15}

Trap accesses to System registers in the AArch32 (coproc==0b1111) encoding space, by the value of *n*, where *n* is:

- The numeric value of the CRn argument used when accessing the register using an MCR or MRC instruction.
- The numeric value of the CRm argument used when accessing the register using an MCRR or MRRC instruction.

Controls provided by the **MDCR_EL2**

MDCR_EL2.{TDRA, TDOSA, TDA}

Trap controls, that control traps to EL2 of Non-secure EL1 and EL0 System register accesses to the following:

- TDRA** The Debug ROM registers.
TDOSA The OS-related debug registers.
TDA Those debug registers not included in either of the **MDCR_EL2.TDRA** or **MDCR_EL2.TDOSA** traps.

MDCR_EL2.TDE Routes all debug exceptions taken from Non-secure EL1 and EL0 to EL2.

MDCR_EL2.{TPM, TPMCR}

These are trap controls, that control traps to EL2 of Non-secure EL1 and EL0 accesses to the following registers:

- TPM** All Performance Monitors registers.
TPMCR The Performance Monitors Control Registers.

MDCR_EL2.HPMN Defines the number of Performance Monitors counters that are accessible from Non-secure EL1 and EL0.

Controls provided at EL1

See:

- [Controls provided by the SCTLR_EL1.](#)
- [Controls provided by the MDSCR_EL1 on page D1-1545.](#)

Controls provided by the **SCTLR_EL1**

SCTLR_EL1.{A, SA} Enable alignment checking:

- A** On data accesses from EL1 and EL0.
SA On the SP, when executing at EL1.

SCTLR_EL1.SA0 Enable alignment checking on the SP when executing at EL0.

SCTLR_EL1.{M, C, I, WXN}

Memory system control bits:

- M** Enables EL1&0 stage 1 address translation.
C When set to 0, makes data accesses to Normal memory from EL0 and EL1, and Normal memory accesses to the EL1&0 stage 1 translation tables, Non-cacheable.
I When set to 0, makes instruction accesses to Normal memory from EL1 and EL0 Non-cacheable.

WXN For accesses from EL1 and EL0, enables treating all writable memory regions as XN, execute never.

SCTLR_EL1.EE Defines the endianness of data accesses from EL1, including stage 1 translation table walks at EL1 and EL0.

———— **Note** —————

Instruction fetches are always little-endian.

SCTLR_EL1.E0E EL0 Endianness. Defines the endianness used for explicit data accesses made from EL0.

SCTLR_EL1.{UCI, UCT, DZE, nTWI, nTWE}

Trap enables:

UCI Unprivileged Cache maintenance Instruction enable.

UCT Unprivileged Cache Type access enable.

DZE Data cache Zero Enable.

nTWI Not Trap Wait-For-Interrupt.

nTWE Not Trap Wait-For-Event.

SCTLR_EL1.UMA Unprivileged Mask Access.

SCTLR_EL1.{SED, ITD, CP15BEN}

These bits control the use, at EL0, of AArch32 functionality that is deprecated, or OPTIONAL and deprecated:

SED Disables use of the SETEND instruction.

ITD If supported, disables some uses of the IT instruction. The register field description identifies the uses that are disabled.

CP15BEN If supported, enables use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) memory barrier instructions.

The deprecated uses of the IT instruction, and use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) instructions, are deprecated for performance reasons. Implementation of the ITD and CP15BEN controls is optional, and if a control is not implemented then the associated AArch32 functionality cannot be disabled.

Controls provided by the MDSCR_EL1

MDSCR_EL1.{MDE, SS}

Enable controls for the debug exceptions:

MDE Enables Breakpoint exceptions, Watchpoint exceptions, and Vector Catch exceptions.

SS Enables Software Step exceptions.

There is no enable control for Breakpoint Instruction exceptions. Breakpoint Instruction exceptions are always enabled.

MDSCR_EL1.KDE Enables debug exceptions from EL_D when EL_D is using AArch64.

MDSCR_EL1.TDCC Enables a trap to EL1 of EL0 accesses to the Debug Communications Channel registers.

D1.12.2 Control of SIMD, floating-point and trace functionality

In addition to the controls described in *The hierarchy of configuration and routing control* on page D1-1540, the following registers provide a hierarchy of control of access to SIMD and floating-point functionality, and to trace functionality that is accessible using the System registers:

CPTR_EL3 Traps operation at lower Exception levels to EL3, if the operation is not trapped to EL2 by **CPTR_EL2** and is not trapped to EL1 by **CPACR_EL1**.

CPTR_EL2 Traps operation in Non-secure EL1 or EL0 to EL2, if the operation is not trapped to EL1 by **CPACR_EL1**. **CPTR_EL2**.{TTA, TFP} also trap operation in EL2.

The trap bits in the **CPTR_EL3** and **CPTR_EL2** are as follows:

TCPAC Traps accesses to the registers that control access to SIMD, floating-point, and trace functionality.

TTA Traps any System register access to trace functionality, unless that access is otherwise trapped to a lower Exception level.

TFP Traps any execution of an instruction that uses the SIMD and floating-point register bank, unless that access is otherwise trapped to a lower Exception level.

CPACR_EL1 Traps operation from EL1 or EL0 to EL1. Traps set in the **CPACR_EL1** take precedence over any traps set in the **CPTR_EL2** or **CPTR_EL3**. The trap fields are as follows:

TTA Traps to EL1 any System register access from EL0 or EL1 to trace functionality.

FPEN Traps to EL1 execution of instructions that uses the SIMD and floating-point register bank.

D1.12.3 Control of IMPLEMENTATION DEFINED features

The hierarchy of configuration and routing control on page D1-1540 and *Control of SIMD, floating-point and trace functionality* describe the controls of the trapping of architecturally-defined functionality. However, the architecture also defines registers that can be used to provide IMPLEMENTATION DEFINED traps of IMPLEMENTATION DEFINED functionality to the different Exception levels. [Table D1-10](#) shows these control registers, for AArch64 state controls.

Table D1-10 Control of traps of IMPLEMENTATION DEFINED functionality

| Traps to EL3 | Traps to EL2 | Traps to EL1 | Notes |
|---------------------------|---------------------------|---------------------------|---|
| ACTLR_EL3 | ACTLR_EL2 | ACTLR_EL1 | Registers also provide IMPLEMENTATION DEFINED configuration controls for the appropriate Exception level. |
| - | HACR_EL2 | - | Provides traps of IMPLEMENTATION DEFINED Non-secure EL1 and EL0 functionality to EL2. |

D1.13 Synchronous exception types, routing and priorities

Synchronous exceptions are:

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
 - Attempts to execute instructions at an inappropriate Exception level.
 - Attempts to execute instructions when they are disabled.
 - Attempts to execute instruction bit patterns that have not been allocated.
- Illegal Execution state exceptions. These are caused by attempts to execute an instruction when the value of `PSTATE.IL` is 1, see [Illegal return events from AArch64 state on page D1-1537](#).
- Exceptions caused by the use of a misaligned SP.
- Exceptions caused by attempting to execute an instruction with a misaligned PC.
- Exceptions caused by the exception-generating instructions SVC, HVC, or SMC.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. See [Configurable instruction enables and disables, and trap controls on page D1-1562](#).
- Instruction Aborts generated by the memory address translation system that are associated with attempts to execute instructions from areas of memory that generate faults.
- Data Aborts generated by the memory address translation system that are associated with attempts to read or write memory that generate faults.
- Data Aborts caused by a misaligned address.
- All of the debug exceptions:
 - Breakpoint Instruction exceptions.
 - Breakpoint exceptions.
 - Watchpoint exceptions.
 - Vector Catch exceptions.
 - Software Step exceptions.
- In an implementation that supports the trapping of floating-point exceptions, exceptions caused by trapped IEEE floating-point exceptions, see [Floating-point exception traps on page D1-1552](#).
- In some implementations, External aborts. External aborts are failed memory accesses, and include accesses to those parts of the memory system that occur during the address translation. The ARMv8 architecture permits, but does not require, implementations to treat such exceptions synchronously. See [External aborts on page D3-1714](#).

This remainder of this section contains the following:

- [Routing exceptions to EL2 on page D1-1548](#).
- [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#).
- [Effect of Data Aborts on page D1-1551](#).
- [Floating-point exception traps on page D1-1552](#).

D1.13.1 Routing exceptions from Non-secure EL0 to EL2

When [HCR_EL2.TGE](#) is 1, any exception taken from Non-secure EL0 that would be taken to Non-secure EL1 is, instead, routed to EL2. This means that an application can execute at Non-secure EL0 without using any functionality at Non-secure EL1.

———— **Note** —————

Implementations typically use the following Exception level and software hierarchy in Non-secure state:

| | |
|------------|-------------------|
| EL2 | Hypervisor. |
| EL1 | Operating system. |
| EL0 | Application. |

In such an implementation, setting [HCR_EL2.TGE](#) to 1 means that an application can run at Non-secure EL0 under the direct control of a hypervisor executing at EL2, with no operating system involvement.

D1.13.2 Synchronous exception prioritization for exceptions taken to AArch64

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. For exceptions taken to an Exception level that is using AArch64, these are prioritized as follows, where 1 is the highest priority.

———— **Note** —————

The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch64. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#).

1. Software Step exceptions. See [Software Step exceptions on page D2-1673](#).
2. PC alignment fault exceptions. See [PC alignment checking on page D1-1515](#).
3. Instruction Abort exceptions. See [Exception from an Instruction abort on page D1-1533](#) and [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-1807](#).
4. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
 - [Breakpoint exceptions on page D2-1641](#).
 - [Vector Catch exceptions on page D2-1672](#).

Vector Catch exceptions are only taken from AArch32 state.

———— **Note** —————

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#). This means that it is outside the scope of the description of this section.

5. Illegal Execution state exceptions. See [Illegal return events from AArch64 state on page D1-1537](#).
6. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
 - [HSTR_EL2.Tn](#).
 - [HCR_EL2.TIDCP](#).

———— **Note** —————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [HSTR.Tn](#) and [HCR.TIDCP](#).

7. Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons:
- Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
 - Attempting to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
 - Debug state execution of an instruction encoding that is unallocated in Debug state.
 - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
 - Execution of an HVC instruction, when HVC instructions are disabled by [SCR_EL3.HCE](#) or [HCR_EL2.HCD](#).
 - Execution of an MSR or MRS instruction to [SP_EL0](#) when the value of [SPSel](#) is 0.
 - Execution of an HLT instruction when HLT instructions are disabled by [EDSCR.HDE](#).
 - In Debug state:
 - Execution of a DCPS1 instruction in Non-secure EL0 when [HCR_EL2.TGE](#) is 1.
 - Execution of a DCPS2 instruction in EL1 or EL0 when [SCR_EL3.NS](#) is 0 or when EL2 is not implemented.
 - Execution of a DCPS3 instruction when [EDSCR.SDD](#) is 1 or when EL3 is not implemented.
 - When the value of [EDSCR.SDD](#) is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
 - When executing in AArch32 state, execution of an instruction that is UNDEFINED as a result of any of:
 - Being in an IT block when [SCTLR_EL1.ITD](#) is 1.
 - Executing a SETEND instruction executed [SCTLR_EL1.SED](#).
 - Executing a [CP15DMB](#), [CP15DSB](#), or [CP15ISB](#) barrier instruction when [SCTLR_EL1.CP15BEN](#) is 0.

———— **Note** —————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [SCTLR](#).{ITD, SED, CP15BEN}, with additional controls [HSCTLR](#).{ITD, SED, CP15BEN}.

See [Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1567](#)

- When executing in AArch32 state, execution of an instruction that is UNDEFINED because at least one of [FPCR](#).{Stride, Len} is nonzero, when programming these bits to nonzero values is supported. See [Floating-point exception traps on page G1-3883](#).

———— **Note** —————

- This case applies only when EL0 is using AArch32 and EL1 is using AArch64. The exception generated by the attempted execution at EL0 of the UNDEFINED instruction is taken to EL1 using AArch64.
- When EL1 is using AArch32, the corresponding controls are [FPSCR](#).{Stride, Len}, and any exception generated by the attempted execution at EL0 or EL1 of an instruction that is UNDEFINED because of a nonzero {Stride, Len} value is taken to EL1 using AArch32.

8. Exceptions taken to EL1, or taken to EL2 because the value of [HCR_EL2.TGE](#) is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-7.

———— **Note** —————

When EL2 is using AArch32, the equivalent control for routing exceptions to EL2 is [HCR.TGE](#).

9. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
- [HSTR_EL2.Tn](#).
 - [HCR_EL2.TIDCP](#).

———— **Note** —————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state the equivalent controls are [HSTR.Tn](#) and [HCR.TIDCP](#).

10. Exceptions taken to EL2 because of configuration settings in the [CPTR_EL2](#).

———— **Note** —————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are in the [HCPTR](#).

11. Exceptions taken to EL2 because of one of the following configuration settings:

- Any setting in [HCR_EL2](#), other than the TIDCP bit.
- Any setting in [CNTHCTL_EL2](#).
- Any setting in [MDCR_EL2](#).

———— **Note** —————

These are the controls for exceptions taken to AArch64 state. For exceptions taken to AArch32 state, the equivalent controls are:

- Any setting in [HCR](#), other than the TIDCP bit.
- Any setting in [CNTHCTL](#) or [HDCR](#).

12. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities 1 - 11.
13. Exceptions caused by the SMC instruction being UNDEFINED because the value of [SCR_EL3.SMD](#) is 1.
14. Exceptions caused by the execution of an Exception generating instruction:
- For exceptions taken from AArch64 state, [Branches, Exception generating, and System instructions on page C3-142](#) defines these instructions.
 - When executing in AArch32 state, the exception-generating instructions are SVC, HVC, SMC, and BKPT.
15. Exceptions taken to EL3 because of configuration settings in the [CPTR_EL3](#).
16. Exceptions taken to EL3 from Secure EL1 using AArch32, because of execution of the instructions listed in [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590](#).
17. Exceptions taken to EL3 from EL0, EL1, or EL2 because of configuration settings in the [MDCR_EL3](#).
18. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities 1 - 17.
19. Trapped floating-point exceptions, if supported. See [Floating-point exception traps on page D1-1552](#).
20. SP alignment faults. See [SP alignment checking on page D1-1515](#).
21. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item 23. See [Exception from a Data abort on page D1-1533](#) and [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-1807](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 23.
22. Watchpoint exceptions. See [Watchpoint exceptions on page D2-1657](#).

23. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see [External aborts on page D3-1714](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item 21.

For items 21-23, if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

———— **Note** —————

Exceptions generated by a translation table walk are reported and prioritized as either an Instruction Abort exception, priority 3 in this list, or a Data Abort exception, priority 21 in this list. See also [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-1807](#).

D1.13.3 Effect of Data Aborts

If an instruction that stores to memory generates a Data Abort, the value of each memory location that instruction stores to is either:

- Unchanged, if one of the following applies:
 - An MMU fault is generated.
 - A Watchpoint exception is generated.
 - An external abort is generated, if that external abort is taken synchronously.

———— **Note** —————

If an external abort is taken asynchronously, using the SError interrupt, it is outside the scope of the architecture to define the effect of the store on the memory location, because it depends on the system-specific nature of the external abort. However, in general, ARM recommends that such memory locations are not updated.

- UNKNOWN for any location for which no exception and no debug event is generated.

For external aborts and Watchpoint exceptions, the size of a memory location is defined as being the size for which a memory access is single-copy atomic.

———— **Note** —————

For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page B2-82](#).

For Data Aborts from load or store instructions executed in AArch64 state, if the:

Data Abort is taken synchronously

- If the load or store instruction specifies writeback of a new base address, the base address is restored to the original value on taking the exception.
- If the instruction was a load to either the base address register or the offset register, that register is restored to the original value. Any other destination registers become UNKNOWN.
- If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.

Data Abort is taken asynchronously, using the SError interrupt

If the instruction was a load, the destination registers of the load take an UNKNOWN value if the SError interrupt is taken at a point in the instruction stream after the load.

D1.13.4 Floating-point exception traps

Execution of a floating-point instruction, or an Advanced SIMD instruction that performs floating-point operations, can generate an exceptional condition, called a *floating-point exception*.

Note

In AArch64 state, a floating-point instruction performs only a single floating-point operation. However, an Advanced SIMD instruction that operates on floating-point values can perform multiple floating-point operations. Therefore, this section describes the handling of a floating-point exception on an *operation*, rather than on an *instruction*.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} are the control bits that enable synchronous exception generation for each of the different floating-point exceptions.
- For an implementation that does not provide this capability, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits are RAZ/WI.

Note

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, unless they are taken from Non-secure state when the value of **HCR_EL2.TGE** is 1, when they are taken to EL2 instead.
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

The exception is reported in the **ESR_ELx** for the Exception level to which it is taken.

In an implementation that includes synchronous exception generation for floating-point exceptions in AArch64 state:

- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception bits in the event of such an exception. For more information see [Combinations of floating-point exceptions on page D1-1553](#).
- When the execution of separate operations in separate SIMD elements causes multiple floating-point exceptions, the **ESR_ELx** reports one exception associated with one element that the instruction uses. The architecture does not specify which element is reported, however **ESR_ELx** identifies the reported element.

The `AArch64.FPTrappedException()` and `FPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch64 state.

Combinations of floating-point exceptions

Many pseudocode functions perform *floating-point operations*, including `FixedToFP()`, `FPAAdd()`, `FPCompare()`, `FPCompareEQ()`, `FPCompareGE()`, `FPCompareGT()`, `FPDiv()`, `FPMMax()`, `FPMMin()`, `FPMul()`, `FPMulAdd()`, `FPRecipEstimate()`, `FPRecipStepFused()`, `FPRSqrtEstimate()`, `FPRSqrtStepFused()`, `FPSqrt()`, `FPSub()`, and `FPToFixed()`. All of these operations can generate floating-point exceptions.

———— Note —————

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
- The floating-point operation behavior described in the following sections does not apply to them:
 - [Flush-to-zero on page A1-49](#).
 - [NaN handling and the Default NaN on page A1-50](#).

More than one floating-point exception can occur on the same operation. The only combinations of exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other exceptions.

The priority order of these floating-point exceptions is that the Inexact exception is treated as lowest priority, and the Input Denormal exception is treated as highest priority.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, an exception on one operation is treated as higher priority than an exception on another operation if the occurrence of the second exception depends on the result of the first operation. Otherwise, it is `CONSTRAINED UNPREDICTABLE` which exception is treated as higher priority, where the exception prioritized might differ between different instances of the same two floating-point exceptions being generated on the same operation during execution of the instruction.

When none of the floating-point exceptions caused by an operation is trapped, any floating-point exception that occurs causes the associated cumulative bit in the `FPSR` to be set to 1.

When a floating-point exception is trapped:

- It is `IMPLEMENTATION DEFINED` whether the `FPSR` is restored when the trapped exception is taken. If the `FPSR` is not restored then, then it is `CONSTRAINED UNPREDICTABLE` which untrapped floating-point exception, if any, are indicated by the corresponding `FPSR` cumulative exception bits having the value 1.
- In the `ESR_ELx` for the Exception level to which the trapped exception is taken, the value of the floating-point exception trapped bit for the highest priority trapped floating-point exception must be 1.

In this `ESR_ELx`:

- The value of the floating-point exception trapped bit for any other untrapped floating-point exception generated by the same operation must be 0. This applies to both higher priority and lower priority untrapped floating point exceptions.
- The value of the floating-point exception trapped bit for any lower priority trapped floating-point exception generated by the same operation might be 1, but the architecture does not require this.

For trapped floating-point exceptions from Advanced SIMD instructions, the architecture does not define the exception prioritization between different elements of the instruction. The architectural requirements for floating-point exception prioritization apply only to multiple floating-point exceptions generated on the same element of an Advanced SIMD operation.

———— **Note** —————

An implementation might provide information about a lower priority or untrapped floating-point exceptions in an IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

D1.14 Asynchronous exception types, routing, masking and priorities

In the ARMv8-A architecture, asynchronous exceptions that are taken to AArch64 state are also known as *interrupts*.

There are two types of interrupts:

Physical interrupts Are signals sent to the PE from outside the PE. They are:

- SError. System Error.
- IRQ.
- FIQ.

Virtual interrupts Are interrupts that software executing at EL2 can enable and make pending. A virtual interrupt is taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1.

Virtual interrupts have names that correspond to the physical interrupts:

- vSError.
- vIRQ.
- vFIQ.

Note

- For information about how virtual interrupts might be used see [Virtual interrupt usage model on page D1-1505](#).
- The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception, and means that it is categorized as a unique exception class, with EC encoding 0x2F.

An external abort generated by the memory system might be taken asynchronously using the SError interrupt. The effect of a failed memory access is described in [Effect of Data Aborts on page D1-1551](#).

Each physical interrupt type can be assigned a target Exception level of EL1, EL2 or EL3, as shown in [Asynchronous exception routing on page D1-1556](#).

When an interrupt occurs:

- On taking an SError or a vSError interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is updated with the encoding for an SError interrupt. See [Exception classes and the ESR_ELx syndrome registers on page D1-1523](#).
- On taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, the Exception Syndrome register for that Exception level is not updated.

The remainder of this section contains the following:

- [Asynchronous exception routing on page D1-1556](#).
- [Asynchronous exception masking on page D1-1557](#).
- [Virtual interrupts on page D1-1558](#).
- [Prioritization and recognition of interrupts on page D1-1560](#).
- [Taking an interrupt or other exception during a multiple-register load or store on page D1-1560](#).

D1.14.1 Asynchronous exception routing

The following tables show the routing of physical interrupts when the highest implemented Exception level is using AArch64.

In the tables, C indicates that the interrupt is not taken, regardless of the Process state interrupt mask.

Table D1-11 Routing when both EL3 and EL2 are implemented

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | SCR_EL3.RW | AMO ^a IMO ^a FMO ^a | Target Exception level when executing in: | | | | | |
|--|------------|--|---|-----|-----|--------|-----|-----|
| | | | Non-secure | | | Secure | | |
| | | | EL0 | EL1 | EL2 | EL0 | EL1 | EL3 |
| 0 | 0 | 0 | EL1 | EL1 | EL2 | EL1 | EL1 | C |
| | X | 1 | EL2 | EL2 | EL2 | EL1 | EL1 | C |
| | 1 | 0 | EL1 | EL1 | C | EL1 | EL1 | C |
| 1 | X | X | EL3 | EL3 | EL3 | EL3 | EL3 | EL3 |

- a. If EL2 is using AArch64, these are the [HCR_EL2](#).{AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the [HCR](#){AMO, IMO, FMO} control bits. If [HCR_EL2.TGE](#) or [HCR.TGE](#) is 1, these bits are treated as being 1 other than for a direct read.

Table D1-12 Routing when EL3 is implemented and EL2 is not implemented

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | Target Exception level when executing in: | | | | |
|--|---|-----|--------|-----|-----|
| | Non-secure | | Secure | | |
| | EL0 | EL1 | EL0 | EL1 | EL3 |
| 0 | EL1 | EL1 | EL1 | EL1 | C |
| 1 | EL3 | EL3 | EL3 | EL3 | EL3 |

Table D1-13 Routing when EL3 is not implemented and EL2 is implemented

| HCR_EL2.AMO ^a HCR_EL2.IMO ^a HCR_EL2.FMO ^a | Target Exception level when executing in: | | |
|--|---|-----|-----|
| | Non-secure | | |
| | EL0 | EL1 | EL2 |
| 1 | EL2 | EL2 | EL2 |
| 0 | EL1 | EL1 | C |

- a. If [HCR_EL2.TGE](#) is 1, these bits are treated as being 1 other than for a direct read.

D1.14.2 Asynchronous exception masking

When an interrupt is masked, it means that it cannot be taken. Instead, it remains pending.

When executing in AArch64 state, interrupts are masked implicitly when the target Exception level of the interrupt is lower than the current Exception level.

In addition, interrupts can be masked when the target Exception level is the current Exception level. The controls for this are:

SError [PSTATE.A](#)
IRQ [PSTATE.I](#)
FIQ [PSTATE.F](#)

When the target Exception level is higher than the current Exception level:

- If the target Exception level is EL2 or EL3, the interrupt cannot be masked by the [PSTATE](#).{A, I, F} bits.
- If the target Exception level is EL1, the interrupt can be masked by the [PSTATE](#).{A, I, F} bits.

———— **Note** —————

- The ability to execute in EL0 with interrupts to EL1 masked is required by some user level driver code.
- The [PSTATE](#).{A, I, F} bits can mask both physical interrupts and virtual interrupts.
- The ARMv8-A architecture does not support *Non-maskable FIQ* (NMFI) operations. This means that it does not provide a configuration option to override the masking of FIQs by [PSTATE.F](#).

On taking any exception to an Exception level using AArch64, all of [PSTATE](#).{A, I, F} are set to 1, masking all interrupts that target that Exception level.

The following tables show the masking of physical interrupts when the highest implemented Exception level is using AArch64:

- For implementations that include both EL2 and EL3, see [Table D1-14](#).
- For implementations that include EL3 but not EL2, see [Table D1-15 on page D1-1558](#).
- For implementations that include EL2 but not EL3, see [Table D1-16 on page D1-1558](#).

For the masking of virtual interrupts, see [Virtual interrupts on page D1-1558](#).

In the tables:

- A** When the interrupt is asserted it is taken regardless of the value of the Process state interrupt mask.
- B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
- C** When the interrupt is asserted it is not taken, regardless of the value of the Process state interrupt mask.

Table D1-14 Physical interrupt masking when both EL3 and EL2 are implemented

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | SCR_EL3.RW | AMO^a IMO^a FMO^a | Target Exception level | Effect of the interrupt mask when executing in: | | | | | |
|--|----------------------------|--|---------------------------------------|--|------------|------------|---------------|------------|------------|
| | | | | Non-secure | | | Secure | | |
| | | | | EL0 | EL1 | EL2 | EL0 | EL1 | EL3 |
| 0 | 0 | 0 | EL1 | B | B | B | B | B | C |
| | | 1 | EL2 | A | A | B | B | B | C |
| | 1 | 0 | EL1 | B | B | C | B | B | C |
| | | 1 | EL2 | A | A | B | B | B | C |

Table D1-14 Physical interrupt masking when both EL3 and EL2 are implemented (continued)

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | SCR_EL3.RW | AMO ^a IMO ^a FMO ^a | Target Exception level | Effect of the interrupt mask when executing in: | | | | | |
|--|------------|--|------------------------------|---|-----|-----|--------|-----|-----|
| | | | | Non-secure | | | Secure | | |
| | | | | EL0 | EL1 | EL2 | EL0 | EL1 | EL3 |
| 1 | X | X | EL3 | A | A | A | A | A | B |

a. If EL2 is using AArch64, these are the [HCR_EL2](#).{AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the [HCR](#){AMO, IMO, FMO} control bits. If [HCR_EL2](#).TGE or [HCR](#).TGE is 1, these bits are treated as being 1 other than a direct read.

Table D1-15 Physical interrupt masking when EL3 is implemented and EL2 is not implemented

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | Target Exception level | Effect of the interrupt mask when executing in: | | | | |
|--|------------------------------|---|-----|--------|-----|-----|
| | | Non-secure | | Secure | | |
| | | EL0 | EL1 | EL0 | EL1 | EL3 |
| 0 | EL1 | B | B | B | B | C |
| 1 | EL3 | A | A | A | A | B |

Table D1-16 Physical interrupt masking when EL3 is not implemented and EL2 is implemented

| HCR_EL2.AMO ^a HCR_EL2.IMO ^a HCR_EL2.FMO ^a | Target Exception level | Effect of the interrupt mask when executing in: | | |
|--|------------------------------|---|-----|-----|
| | | Non-secure | | |
| | | EL0 | EL1 | EL2 |
| 0 | EL1 | B | B | C |
| 1 | EL2 | A | A | B |

a. If [HCR_EL2](#).TGE is 1, these bits are treated as being 1 other than for a direct read.

D1.14.3 Virtual interrupts

When the value of [HCR_EL2](#).TGE is 0, setting an [HCR_EL2](#).{FMO, IMO, AMO} routing control bit to 1 enables the corresponding virtual interrupt. When the value of [HCR_EL2](#).TGE is 1 all virtual interrupts are disabled.

Virtual interrupts can only be taken from Non-secure EL0 or Non-secure EL1 to Non-secure EL1. When a virtual interrupt type is enabled, that type of interrupt can be generated by:

- Software setting the corresponding virtual interrupt pending bit, [HCR_EL2](#).{VSE, VI, VF}, to 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the *ARM Generic Interrupt Controller Architecture Specification*.

———— **Note** ————

For a usage model for virtual interrupts, see [Virtual interrupt usage model on page D1-1505](#).

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the [ISR_EL1](#).

Each virtual interrupt type can be masked when execution is in Non-secure EL1 or EL0, by using the same Process State mask bits that mask the physical interrupts, [PSTATE](#).{A, I, F}.

When execution is in Secure state, or at EL2, all types of virtual interrupt are always masked.

[Table D1-17](#) summarizes the bits that enable virtual interrupts and the bits that cause virtual interrupts to be pending.

Table D1-17 HCR_EL2 interrupt control bits

| Virtual interrupt type | Enable control ^a | Cause a virtual interrupt to be pending |
|------------------------|-----------------------------|---|
| vSError | HCR_EL2.AMO | HCR_EL2.VSE |
| vIRQ | HCR_EL2.IMO | HCR_EL2.VI |
| vFIQ | HCR_EL2.FMO | HCR_EL2.VF |

a. Applies only when the value of [HCR_EL2.TGE](#) is 0, otherwise the virtual interrupts are disabled.

On taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in the [HCR_EL2](#) retains its state.

On taking a vSError interrupt, [HCR_EL2.VSE](#) is cleared to 0.

———— **Note** ————

This means that if the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

As with physical interrupts:

- Taking a vSError interrupt to an Exception level using AArch64 updates [ESR_EL1](#) with the dedicated encoding for an SError interrupt. For the encoding, see [Exception classes and the ESR_ELx syndrome registers on page D1-1523](#).
- Taking a vIRQ or a vFIQ interrupt to an Exception level using AArch64 does not update the [ESR_EL1](#).

The following table shows the masking of virtual interrupts when the highest implemented Exception level is using AArch64. In the table:

- B** When the interrupt is asserted it is subject to the corresponding Process state mask. If the value of the mask is 1 then the interrupt is not taken. If the value of the mask is 0 the interrupt is taken.
- C** When the interrupt is asserted it is not taken, regardless of the value of the Process state mask.

Table D1-18 Virtual interrupt masking

| SCR_EL3.EA SCR_EL3.IRQ SCR_EL3.FIQ | FMO ^a IMO ^a AMO ^a | TGE ^a | Effect of the interrupt mask when executing in: | | | | | |
|--|--|------------------|---|-----|-----|--------|-----|-----|
| | | | Non-secure | | | Secure | | |
| | | | EL0 | EL1 | EL2 | EL0 | EL1 | EL3 |
| X | 0 | x | C | C | C | C | C | C |
| X | 1 | 0 | B | B | C | C | C | C |
| X | 1 | 1 | C | C | C | C | C | C |

- a. If EL2 is using AArch64, these are the `HCR_EL2`{TGE, AMO, IMO, FMO} control bits. If EL2 is using AArch32, these are the `HCR`{TGE, AMO, IMO, FMO} control bits.

D1.14.4 Prioritization and recognition of interrupts

The ARMv8-A architecture does not define when interrupts are taken. The prioritization of interrupts, including virtual interrupts, is IMPLEMENTATION DEFINED.

———— **Note** ————

As indicated at the start of *Asynchronous exception types, routing, masking and priorities on page D1-1555*, in AArch64 state all possible asynchronous exceptions are defined as *interrupts*.

Any interrupt that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event, provided that the pending interrupt is not masked:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Exit from Debug state.

———— **Note** ————

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define whether the PE takes the interrupt or the synchronous exception first.
- The `ISR_EL1` identifies any pending interrupts.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an interrupt, the architecture only requires that unmasked pending interrupts are taken in finite time.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first *Context synchronization event* after the interrupt was changed to not pending.

D1.14.5 Taking an interrupt or other exception during a multiple-register load or store

In AArch64 state, interrupts can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

If an interrupt, or another exception, is taken from AArch64 during the execution of an instruction that performs a sequence of memory accesses, rather than a single single-copy atomic access, then:

- For a load, any register being loaded by the instruction other than ones used in the generation of the address by the instruction, can contain an UNKNOWN value. Registers used in the generation of the address are restored to their initial value.
- For a store, any data location being stored to by the instruction can contain an UNKNOWN value.
- For either a load or a store, if the instruction specifies writeback of the base address, then that register is restored to its initial value.

———— **Note** ————

- This interrupt behavior is in contrast to behavior in AArch32 state, when interrupts cannot be taken during a sequence of memory access caused by a single load or store instruction.
- In both Execution states, synchronous data abort exceptions can be taken during the execution of an instruction that performs a sequence of memory accesses.

- Software must avoid using multiple-register load and store instructions for accesses to Device memory, particularly to Device memory with the non-Gathering attribute, because an exception taken during the load or store can result in repeated accesses.
-

D1.15 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch64 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an *instruction enable*, an *instruction disable*, or a *trap control*:

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Exception level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

Trap controls A trap control determines whether one or more particular instructions, whenever executed at a particular Exception level, are *trapped*.

A trapped instruction generates a *Trap exception*.

For trap controls provided by:

- EL1** Trap exceptions are taken to EL1, unless routed from Non-secure EL0 to EL2 because [HCR_EL2.TGE](#) is 1 as described in [Routing exceptions to EL2 on page D1-1548](#). For descriptions of these controls see [EL1 configurable controls on page D1-1563](#).
- EL2** Trap exceptions are taken to EL2. For descriptions of these controls see [EL2 configurable controls on page D1-1571](#).
- EL3** Trap exceptions are taken to EL3. For descriptions of these controls see [EL3 configurable controls on page D1-1589](#).

Note

The definitions of *traps* and *enables and disables* overlap, and the classification of some controls is historical. In AArch64 state, the most significant characteristic of an exception report is the [ESR_ELx.EC](#) value with which it is reported. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported.

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if both of the following apply:

- The instruction generating the exception does not also generate a higher priority exception. [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) defines the prioritization of different exceptions on the same instruction.
- The instruction is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state it is executed in. UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of these controls, but the architecture does not require them to do so.

Exceptions generated as a result of these controls are synchronous exceptions.

Exceptions are reported in the [ESR_ELx](#), with an EC value that indicates the Exception class, and:

- Many cases, including all traps, are reported with a non-zero EC value and an associated syndrome.
- Some cases where an instruction is UNDEFINED are reported with an EC value `0x00`, the value for an exception for an unknown or uncategorized reason, and in these cases no syndrome is provided. [ISS encoding for exceptions with an unknown reason on page D7-1938](#) identifies the cases that are reported with EC value `0x00`.

Table D1-8 on page D1-1524 lists the EC values that are used for exceptions that result from traps, enables, and disables.

Note

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, `SCTLR_EL1.DZE` is a trap control even though DZE means DC ZVA Enable.
- In addition to the controls described in this section, a *routing control*, `HCR_EL2.TGE`, can be used to route exceptions from EL0 to EL2. See *Routing exceptions to EL2* on page D1-1548.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

This section is organized as follows:

- *Register access instructions.*
- *EL1 configurable controls.*
- *EL2 configurable controls* on page D1-1571.
- *EL3 configurable controls* on page D1-1589.

D1.15.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

D1.15.2 EL1 configurable controls

These controls are in `_EL1` System registers. The resulting exceptions might be taken from either Execution state. `SPSR_EL1.M[4]` indicates which Execution state the exception was taken from.

Table D1-19 shows the `_EL1` System registers that contain these controls.

Table D1-19 `_EL1` registers that contain instruction enables and disables, and trap controls

| Register name | Register description |
|----------------------------|---|
| <code>SCTLR_EL1</code> | System Control Register, EL1 |
| <code>CPACR_EL1</code> | Architectural Feature Access Control Register |
| <code>MDSCR_EL1</code> | Monitor System Debug Control Register |
| <code>PMUSERENR_EL0</code> | Performance Monitors User Enable Register |

Table D1-20 summarizes the controls.

Table D1-20 Instruction enables and disables, and trap controls, provided by EL1

| Control | Control type ^a | Description |
|-------------------------------------|---------------------------|--|
| <code>SCTLR_EL1.UCI</code> | T | <i>Traps to EL1 of EL0 execution of cache maintenance instructions on page D1-1564</i> |
| <code>SCTLR_EL1.UCT</code> | T | <i>Traps to EL1 of EL0 accesses to the <code>CTR_EL0</code> on page D1-1565</i> |
| <code>SCTLR_EL1.{nTWE, nTWI}</code> | T | <i>Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1565</i> |

Table D1-20 Instruction enables and disables, and trap controls, provided by EL1 (continued)

| Control | Control type ^a | Description |
|--|---------------------------|--|
| SCTLR_EL1.DZE | T | Traps to EL1 of EL0 execution of DC ZVA instructions on page D1-1566 |
| SCTLR_EL1.UMA | T | Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks on page D1-1566 |
| SCTLR_EL1.{SED, ITD} | D | Disabling or enabling EL0 use of AArch32 deprecated functionality on page D1-1567 |
| SCTLR_EL1.CP15BEN | E | |

| CNTKCTL_EL1.{ELOPTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} | T | Traps to EL1 of EL0 accesses to the Generic Timer registers on page D1-1569 |
| PMUSERENR_EL0.{ER, CR, SW, EN} | T | Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1570 |

a. See Table D1-21.

Table D1-21 Control types, for exceptions taken to EL1

| Abbreviation | Type | See |
|--------------|---------|--|
| D | Disable | Instruction enables and instruction disables on page D1-1562 |
| E | Enable | Instruction enables and instruction disables on page D1-1562 |
| T | Trap | Trap controls on page D1-1562 |

Traps to EL1 of EL0 execution of cache maintenance instructions

SCTLR_EL1.UCI traps EL0 execution of cache maintenance instructions to EL1:

- 1** EL0 execution of cache maintenance instructions is not trapped to EL1.
- 0** Any attempt to execute a cache maintenance instruction at EL0 is trapped to EL1.

Table D1-22 shows the instructions that are trapped to EL1, and how the exceptions are reported in ESR_EL1.

Table D1-22 Instructions trapped to EL1 when SCTLR_EL1.UCI is 0

| Traps from | Trapped instructions | Syndrome reporting in ESR_EL1 |
|---------------|-------------------------------------|---|
| AArch64 state | DC CVAU, DC CIVAC, DC CVAC, IC IVAU | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| AArch32 state | n/a | n/a |

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the CTR_ELO

SCTLR_EL1.UCT traps EL0 accesses to the CTR_ELO to EL1:

- 1** EL0 accesses to the CTR_ELO are not trapped to EL1.
- 0** EL0 accesses to the CTR_ELO are trapped to EL1.

Table D1-23 shows how the exceptions are reported in ESR_EL1.

Table D1-23 Register accesses trapped to EL1 when SCTLR_EL1.UCT is 0

| Traps from | Register | Syndrome reporting in ESR_EL1 |
|------------|----------|---|
| AArch64 | CTR_ELO | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| AArch32 | n/a | n/a |

- a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 execution of WFE and WFI instructions

SCTLR_EL1.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to EL1:

SCTLR_EL1.nTWE

- 1** EL0 execution of WFE instructions is not trapped to EL1.
- 0** Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTLR_EL1.nTWI

- 1** EL0 execution of WFI instructions is not trapped to EL1.
- 0** Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.

Table D1-24 shows how the exceptions are reported in ESR_EL1.

Table D1-24 Instructions trapped to EL1 when SCTLR_EL1.{nTWE, nTWI} are 0

| Trap control | Traps from | Trapped instructions | Syndrome reporting in ESR_EL1 |
|----------------|-----------------------|----------------------|--|
| SCTLR_EL1.nTWE | Both Execution states | WFE | Trapped WFI or WFE instruction, using EC value 0x01 ^a |
| SCTLR_EL1.nTWI | | WFI | |

- a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

————— Note —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event on page D1-1599.](#)
- [Wait For Interrupt on page D1-1602.](#)

Traps to EL1 of EL0 execution of DC ZVA instructions

[SCTLR_EL1.DZE](#) traps EL0 execution of DC ZVA instructions to EL1:

- 1** EL0 execution of DC ZVA instructions is not trapped to EL1.
- 0** Any attempt to execute a DC ZVA instruction at EL0 is trapped to EL1. Reading the [DCZID_EL0](#) returns a value that indicates that DC ZVA instructions are not implemented.

[Table D1-25](#) shows how the exceptions are reported in [ESR_EL1](#).

Table D1-25 Instruction trapped to EL1 when [SCTLR_EL1.DZE](#) is 0

| Traps from | Trapped instruction | Syndrome reporting in ESR_EL1 |
|---------------|------------------------|---|
| AArch64 state | DC ZVA | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| AArch32 state | n/a | n/a |

- a. If [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR_EL2](#) using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks

[SCTLR_EL1.UMA](#) traps EL0 execution of MSR and MRS instructions that access the [PSTATE.{D, A, I, F}](#) masks to EL1:

- 1** EL0 execution of MSR or MRS instructions that access the [DAIF](#) is not trapped to EL1.
- 0** Any attempt at EL0 to execute an MSR or an MRS instruction that accesses the [DAIF](#) is trapped to EL1.

[Table D1-26](#) shows how the exceptions are reported in [ESR_EL1](#).

Table D1-26 Instructions trapped to EL1 when [SCTLR_EL1.UMA](#) is 0

| Taken from | Disabled instructions | Syndrome reporting in ESR_EL1 |
|---------------|---|---|
| AArch64 state | MRS , MSR (register) , MSR (immediate) , that access the DAIF | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| AArch32 state | n/a | n/a |

- a. If [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR_EL2](#) using the same EC values as shown in the table.

Disabling or enabling EL0 use of AArch32 deprecated functionality

Table D1-27 shows the deprecated AArch32 functionality that might have disable controls in the [SCTLR_EL1](#):

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These [SCTLR_EL1](#) controls apply only to execution at EL0 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL0 using AArch32. The table shows how the exceptions are reported in [ESR_EL1](#).

Table D1-27 EL1 controls for disabling and enabling EL0 use of AArch32 deprecated functionality

| Deprecated AArch32 functionality | Instruction enable or disable in the SCTLR_EL1 | Disabled instructions | Syndrome reporting in ESR_EL1 ^a |
|--|--|--|--|
| SETEND instructions | SED ^b | SETEND instructions | Exception for an unknown reason, using EC value 0x00 |
| Some uses of IT instructions | ITD ^c | See the SCTLR_EL1.IT description | |
| Accesses to the CP15DMB , CP15DSB , and CP15ISB barrier instructions | CP15BEN ^d | MCR accesses to the CP15DMB , CP15DSB , and CP15ISB instructions | |

- If [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure state, the exception is routed to EL2 and reported in [ESR_EL2](#) using the EC value shown in the table.
- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

———— Note ————

- The uses of the IT instruction, and use of the [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) barrier instructions, are deprecated for performance reasons.
- The [SCTLR](#) provides similar controls that apply when EL1 is using AArch32, and the [HSCTLR](#) provides similar controls that apply when EL2 is using AArch32.

Traps to EL1 of EL0 and EL1 System register accesses to the trace registers

[CPACR_EL1.TTA](#) traps EL0 and EL1 System register accesses to the trace registers to EL1.

- | | |
|----------|---|
| 1 | EL0 and EL1 System register accesses to the trace registers are trapped to EL1. |
| 0 | EL0 and EL1 System register accesses to the trace registers are not trapped to EL1. |

———— Note ————

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and the resulting exception is higher priority than a [CPACR_EL1.TTA](#) Trap exception.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page D1-1563](#).

Table D1-28 shows the registers for which accesses are trapped to EL1 when `CPACR_EL1.TTA` is 1, and how the exceptions are reported in `ESR_EL1`.

Table D1-28 Register accesses trapped to EL1 when `CPACR_EL1.TTA` is 1

| Traps from | Registers | Syndrome reporting in <code>ESR_EL1</code> |
|---------------|---------------------------------|--|
| AArch64 state | All implemented trace registers | Trapped AArch64 MSR, MRS, or system instruction, using EC value <code>0x18</code> . ^a |
| AArch32 state | All implemented trace registers | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (<code>coproc==0b1110</code>), using EC value <code>0x05</code>.^a MCRR or MRRC instructions, trapped MCRR or MRRC access (<code>coproc==0b1110</code>), using EC value <code>0x0C</code>.^a |

a. If `HCR_EL2.TGE` is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in `ESR_EL2` using the same EC values as shown in the table.

Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality

`CPACR_EL1.FPEN` traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1:

| | |
|-----------|---|
| 00 | Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped. |
| 01 | Causes any instructions in EL0 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped, but does not cause any instruction in EL1 to be trapped. |
| 10 | Causes any instructions in EL0 or EL1 that use the registers that are associated with Advanced SIMD and floating-point execution to be trapped. |
| 11 | Does not cause any instruction to be trapped. |

Table D1-29 shows the registers for which accesses are trapped, and how the exceptions are reported in `ESR_EL1`.

Table D1-29 Register accesses trapped to EL1 by `CPACR_EL1.FPEN`

| Traps from | Registers | Syndrome reporting in <code>ESR_EL1</code> |
|---|---|--|
| EL0 and EL1 using AArch64, or EL0 using AArch64 only ^a . | <code>FPCR</code> , <code>FPSR</code> , and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1508. | Trapped access to a SIMD or floating-point register, resulting from <code>CPACR_EL1.FPEN</code> or <code>CPTR_ELx.TFP</code> , using EC value <code>0x07</code> ^b |
| EL0 using AArch32 | <code>FPSCR</code> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-3882. | Trapped access to a SIMD or floating-point register, resulting from <code>CPACR_EL1.FPEN</code> or <code>CPTR_ELx.TFP</code> , using EC value <code>0x07</code> ^b |

a. Depending on the value of `CPACR_EL1.FPEN`. See the register description for details.

b. If `HCR_EL2.TGE` is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in `ESR_EL2` using EC value `0x00`.

Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers

`MDSCR_EL1.TDCC` traps EL0 accesses to the DCC registers to EL1:

| | |
|----------|---|
| 1 | EL0 accesses to the DCC registers are trapped to EL1. |
| 0 | EL0 accesses to the DCC registers are not trapped to EL1. |

Traps of AArch32 accesses to `DBGDTRRXint` and `DBGDTRTXint` are ignored in Debug state.

Traps of AArch64 accesses to [DBGDTR_EL0](#), [DBGDTRRX_EL0](#), and [DBGDTRTX_EL0](#) are ignored in Debug state.

[Table D1-30](#) shows the accesses that are trapped, and how the exceptions are reported in [ESR_EL1](#).

Table D1-30 Accesses trapped to EL1 when [MDCR_EL1.TDCC](#) is 1

| Traps from | Trapped accesses | Syndrome reporting in ESR_EL1 |
|---------------|---|---|
| AArch64 state | Accesses to the MDCCSR_EL0 , DBGDTR_EL0 , DBGDTRTX_EL0 and DBGDTRRX_EL0 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| AArch32 state | <ul style="list-style-type: none"> MRC of DBGDSCRint, DBGDTRRXint, and, if implemented, DBGDIDR, DBGDSAR and DBGDRAR. MCR to DBGDTRTXint. | Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 ^a |
| | <ul style="list-style-type: none"> LDC access to DBGDTRTXint. STC access to DBGDTRRXint. | Trapped LDC or STC access, using EC value 0x06 ^a |
| | If implemented, MRRC of DBGDSAR and DBGDRAR . | Trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C ^a |

a. If [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR_EL2](#) using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to the Generic Timer registers

[CNTKCTL_EL1](#).{[ELOPTEN](#), [ELOVTEN](#), [ELOPCTEN](#), [ELOVCTEN](#)} trap EL0 accesses to the Generic Timer registers to EL1, as follows:

- [CNTKCTL_EL1.ELOPTEN](#) traps EL0 accesses to the physical timer registers.
- [CNTKCTL_EL1.ELOVTEN](#) traps EL0 accesses to the virtual timer registers.
- [CNTKCTL_EL1.ELOPCTEN](#) traps EL0 accesses to the frequency register and physical counter register.
- [CNTKCTL_EL1.ELOVCTEN](#) traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

- 1** EL0 accesses are not trapped to EL1.
- 0** EL0 accesses are trapped to EL1.

Accesses to the frequency register, [CNTFRQ_EL0](#) or [CNTFRQ](#), are only trapped if [CNTKCTL_EL1.ELOPCTEN](#) and [CNTKCTL_EL1.ELOVCTEN](#) are both 0.

[Table D1-31](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL1](#).

Table D1-31 Register accesses trapped from EL0 to EL1 by [CNTKCTL_EL1](#) trap controls

| Traps from | Trap control | Registers | Syndrome reporting in ESR_EL1 |
|---------------|--------------------------|---|---|
| AArch64 state | ELOPTEN | CNTP_CTL_EL0 , CNTP_CVAL_EL0 , CNTP_TVAL_EL0 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| | ELOVTEN | CNTV_CTL_EL0 , CNTV_CVAL_EL0 , CNTV_TVAL_EL0 | |
| | ELOPCTEN | CNTFRQ_EL0 , CNTPCT_EL0 | |
| | ELOVCTEN | CNTFRQ_EL0 , CNTVCT_EL0 | |

Table D1-31 Register accesses trapped from EL0 to EL1 by CNTKCTL_EL1 trap controls (continued)

| Traps from | Trap control | Registers | Syndrome reporting in ESR_EL1 |
|---------------|--------------|-----------------------------------|--|
| AArch32 state | ELOPTEN | CNTP_CTL, CNTP_CVAL, CNTP_TVAL | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03^a MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04^a |
| | ELOVTEN | CNTV_CTL, CNTV_CVAL, CNTV_TVAL | |
| | ELOPCTEN | CNTPFRQ, CNTPCT | |
| | ELOVCTEN | CNTPFRQ, CNTVCT | |

a. If HCR_EL2.TGE is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in ESR_EL2 using the same EC values as shown in the table.

Traps to EL1 of EL0 accesses to Performance Monitors registers

PMUSERENR_EL0.{ER, CR, SW, EN} trap EL0 accesses to the Performance Monitors registers to EL1. For each of these controls:

- 1** EL0 accesses are not trapped to EL1.
- 0** EL0 accesses are trapped to EL1.

For those Performance Monitors registers that more than one PMUSERENR_EL0.{ER, CR, SW, EN} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Table D1-32 shows:

- The registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.
- How the exceptions are reported in ESR_EL1.

Table D1-32 Register accesses trapped to EL1 when disabled from EL0

| Traps from | Trap control | Registers | Access type | Syndrome reporting in ESR_EL1 |
|---------------|--------------|---|-------------|---|
| AArch64 state | ER | PMXEVNTR_EL0, PMEVCNTR<n>_EL0 | R | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 ^a |
| | | PMSELR_EL0 | RW | |
| | CR | PMCCNTR_EL0 | R | |
| | SW | PMSWINC_EL0 | W | |
| | EN | PMCNTENSET_EL0, PMCNTENCLR_EL0, PMCR_EL0, PMOVSCLR_EL0, PMSWINC_EL0, PMSELR_EL0, PMCEID0_EL0, PMCEID1_EL0, PMCCNTR_EL0, PMXEVTYPER_EL0, PMEVCNTR_EL0, PMOVSSET_EL0, PMEVCNTR<n>_EL0, PMEVTYPER<n>_EL0, PMCCFILTR_EL0. | RW | |

Table D1-32 Register accesses trapped to EL1 when disabled from EL0 (continued)

| Traps from | Trap control | Registers | Access type | Syndrome reporting in ESR_EL1 |
|---------------|--------------|--|-------------|--|
| AArch32 state | ER | PMXVCNTR , PMEVCNTR<n> | R | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 ^a |
| | | PMSELR | RW | |
| | CR | PMCCNTR , accessed using an MRC | R | Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 ^a |
| | CR | PMCCNTR , accessed using an MRRC | R | |
| | SW | PMSWINC | W | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 ^a |
| | EN | PMCNTENSET , PMCNTENCLR , PMCR , PMOVS , PMSWINC , PMSELR , PMCEID0 , PMCEID1 , PMCCNTR , PMXEVTPER , PMXVCNTR , PMOVSSET , PMEVCNTR<n> , PMEVTPER<n> , PMCCFILTR , accessed using an MCR or MRC | RW | |
| | EN | PMCCNTR , accessed using an MCRR or MRRC | RW | |

a. If [HCR_EL2.TGE](#) is 1 and the PE is in Non-secure state, these Trap exceptions are routed to EL2 and are reported in [ESR_EL2](#) using the same EC values as shown in the table.

D1.15.3 EL2 configurable controls

These controls are in [_EL2](#) System registers. The resulting exceptions might be taken from either Execution state. [SPSR_EL2.M\[4\]](#) indicates which Execution state the exception was taken from.

These controls are ignored in Secure state.

[Table D1-33](#) shows the [_EL2](#) System registers that contain these controls.

Table D1-33 [_EL2](#) registers that contain instruction disables and trap controls

| Register name | Register description |
|--------------------------|---|
| HCR_EL2 | Hypervisor Configuration Register |
| HSTR_EL2 | Hypervisor System Trap Register |
| CPTR_EL2 | Architectural Feature Trap Register, EL2 |
| MDCR_EL2 | Monitor Debug Configuration Register, EL2 |

[Table D1-34](#) on page D1-1572 summarizes the controls.

Note

- There are no instruction enables at EL2.
- For completeness, [Table D1-34](#) on page D1-1572 includes the routing control described in [Routing exceptions to EL2](#) on page D1-1548.

Table D1-34 Instruction disables and trap controls provided by EL2

| Control | Control type^a | Description |
|----------------------------------|---------------------------------|---|
| HCR_EL2.{TRVM, TVM} | T | Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers on page D1-1573 |
| HCR_EL2.HCD | D | Disabling Non-secure state execution of HVC instructions on page D1-1574 |
| HCR_EL2.TDZ | T | Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions on page D1-1574 |
| HCR_EL2.TGE | R | Routing exceptions to EL2 on page D1-1548 |
| HCR_EL2.TTLB | T | Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions on page D1-1574 |
| HCR_EL2.{TSW, TPC, TPU} | T | Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions on page D1-1575 |
| HCR_EL2.TACR | T | Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register on page D1-1576 |
| HCR_EL2.TIDCP | T | Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1577 |
| HCR_EL2.TSC | T | Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578 |
| HCR_EL2.{TID0, TID1, TID2, TID3} | T | Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578 |
| HCR_EL2.{TWI, TWE} | T | Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1581 |
| CPTR_EL2.TCPAC | T | Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR on page D1-1582 |
| CPTR_EL2.TFP | T | General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1583 |
| CPTR_EL2.TTA | T | Traps to EL2 of Non-secure System register accesses to the trace registers on page D1-1583 |
| HSTR_EL2.{T0-T3, T5-T13, T15} | T | General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only on page D1-1584 |
| MDCR_EL2.{TDRA, TDOSA, TDA} | T | Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers on page D1-1585 |
| CNTHCTL_EL2.{EL1PCEN, EL1PCTEN} | T | Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers on page D1-1587 |
| MDCR_EL2.{TPM, TPMCR} | T | Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1588 |

a. See Table D1-35 on page D1-1573.

Table D1-35 Control types, for exceptions taken to EL1

| Abbreviation | Type | See |
|--------------|-----------------|---|
| D | Disable | <i>Instruction enables and instruction disables on page D1-1562</i> |
| R | Routing control | <i>Routing exceptions to EL2 on page D1-1548</i> |
| T | Trap | <i>Trap controls on page D1-1562</i> |

Also see the following for more general information about traps to EL2:

- *Register access instructions on page D1-1563.*
- For traps from an Exception level using AArch32:
 - *Instructions that fail their condition code check on page G1-3896.*
 - *Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-3896.*

Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers

HCR_EL2.{TRVM, TVM} trap Non-secure EL1 accesses to the virtual memory control registers to EL2:

HCR_EL2.TRVM, for read accesses:

- 1** Non-secure EL1 reads of the virtual memory control registers are trapped to EL2.
- 0** Non-secure EL1 reads of the virtual memory control registers are not trapped to EL2.

HCR_EL2.TVM, for write access:

- 1** Non-secure EL1 writes to the virtual memory control registers are trapped to EL2.
- 0** Non-secure writes to the virtual memory control registers are not trapped to EL2.

Table D1-36 shows the registers for which:

- Reads are trapped to EL2 when **HCR_EL2**.TRVM is 1.
- Writes are trapped to EL2 when **HCR_EL2**.TVM is 1.

Table D1-36 also shows how the exceptions are reported in **ESR_EL2**.

Table D1-36 Register read and write accesses trapped when **HCR_EL2.{TRVM, TVM} are 1**

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|--|
| AArch64 state | SCTLR_EL1 , TTBR0_EL1 , TTBR1_EL1 , TCR_EL1 , ESR_EL1 , FAR_EL1 , AFSR0_EL1 , AFSR1_EL1 , MAIR_EL1 , AMAIR_EL1 , CONTEXTIDR_EL1 . | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. |
| AArch32 state | SCTLR , TTBR0 , TTBR1 , TTBCR , DACR , DFSR , IFSR , DFAR , IFAR , ADFSR , AIFSR , PRRR , NMRR , MAIR0 , MAIR1 , AMAIR0 , AMAIR1 , CONTEXTIDR . | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03. Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04. |

———— **Note** —————

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the Non-secure memory system. A hypervisor might use this trap as part of its virtualization of memory management.

Disabling Non-secure state execution of HVC instructions

[HCR_EL2.HCD](#) disables Non-secure state execution of HVC instructions:

- 1** HVC instructions are UNDEFINED at EL2 and Non-secure EL1, and any resulting exception is taken from the current Exception level to the current Exception level.
- 0** HVC instruction execution is enabled at EL2 and Non-secure EL1.

———— **Note** ————

HVC instructions are always UNDEFINED at EL0.

[HCR_EL2.HCD](#) is only implemented if EL3 is not implemented. Otherwise, it is RES0.

[Table D1-37](#) shows how the exceptions are reported in [ESR_ELx](#).

Table D1-37 Instruction disabled when [HCR_EL2.HCD](#) is 1

| Taken from | Disabled instruction | Syndrome reporting in ESR_ELx |
|---------------|----------------------|--|
| AArch64 state | HVC | Exception for an unknown reason, using EC value 0x00 |
| AArch32 state | HVC | |

Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions

[HCR_EL2.TDZ](#) traps Non-secure EL0 and EL1 execution of DC ZVA instructions to EL2:

- 1** Any attempt to execute a DC ZVA instruction at Non-secure EL0 or EL1 is trapped to EL2. Reading the [DCZID_EL0](#) returns a value that indicates that DC ZVA instructions are not implemented.
- 0** Non-secure EL0 and EL1 execution of DC ZVA instructions is not trapped to EL2.

[Table D1-38](#) shows how the exceptions are reported in [ESR_EL2](#).

Table D1-38 Instruction trapped to EL1 when [HCR_EL2.TDZ](#) is 0

| Traps from | Trapped instruction | Syndrome reporting in ESR_EL2 |
|---------------|------------------------|--|
| AArch64 state | DC ZVA | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | n/a | n/a |

Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

[HCR_EL2.TTLB](#) traps Non-secure EL1 execution of TLB maintenance instructions to EL2:

- 1** Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to EL2.
- 0** Non-secure EL1 execution of TLBI instructions is not trapped to EL2.

Table D1-39 shows the instructions that are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-39 Instructions trapped to EL2 when [HCR_EL2.TTLB](#) is 1

| Traps from | Trapped instructions | Syndrome reporting in ESR_EL2 |
|---------------|--|--|
| AArch64 state | TLBI VMALLE1IS , TLBI VAE1IS , TLBI ASIDE1IS , TLBI VAAE1IS , TLBI VALE1IS , TLBI VAALE1IS , TLBI VMALLE1 , TLBI VAE1 , TLBI ASIDE1 , TLBI VAAE1 , TLBI VALE1 , TLBI VAALE1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | TLBIALLIS , TLBIMVAIS , TLBIASIDIS , TLBIMVA AIS , TLBIMVALIS , TLBIMVAALIS , ITLBIALL , ITLBIMVA , ITLBIASID , DTLBIALL , DTLBIMVA , DTLBIASID , TLBIALL , TLBIMVA , TLBIASID , TLBIMVAA , TLBIMVAL , TLBIMVAAL . | Trapped MCR or MRC access (coproc == 0b1111), using EC value 0x03 |

———— **Note** —————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see:

- [TLB maintenance instructions](#) on page D4-1817, for the AArch64 state instructions.
- [The scope of TLB maintenance instructions](#) on page G4-4101, for the AArch32 state instructions.

Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions

[HCR_EL2](#).{TSW, TPC, TPU} trap cache maintenance instructions to EL2 as follows:

- 0** The control has no effect on the execution of cache maintenance instructions.
- 1** Any attempt to execute a corresponding cache maintenance instruction at Non-secure EL1, or at Non-secure EL0 if permitted by [SCTLR_EL1.UCI](#), is trapped to EL2.

Table D1-40 Controls for trapping cache maintenance instructions to EL2

| Trap control | Trapped instructions |
|-----------------------------|---|
| HCR_EL2.TSW | Data or unified cache maintenance by set/way |
| HCR_EL2.TPC | Data or unified cache maintenance to point of coherency |
| HCR_EL2.TPU | Cache maintenance to point of unification |

For:

- [HCR_EL2.TSW == 1](#), [Table D1-41](#) on page D1-1576 shows the instructions that are trapped, and how the exceptions are reported in [ESR_EL2](#).
- [HCR_EL2.TPC == 1](#), [Table D1-42](#) on page D1-1576 shows the instructions that are trapped, and how the exceptions are reported in [ESR_EL2](#).
- [HCR_EL2.TPU == 1](#), [Table D1-43](#) on page D1-1576 shows the instructions that are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-41 Instructions trapped to EL2 when `HCR_EL2.TSW` is 1

| Traps from | Trapped instructions | Syndrome reporting in <code>ESR_EL2</code> |
|---------------|--|--|
| AArch64 state | <code>DC ISW</code> , <code>DC CSW</code> , <code>DC CISW</code> | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | <code>DCISW</code> , <code>DCCSW</code> , <code>DCCISW</code> | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

Note
These instructions are always UNDEFINED at EL0.

Table D1-42 Instructions trapped to EL2 when `HCR_EL2.TPC` is 1

| Traps from | Trapped instructions | Syndrome reporting in <code>ESR_EL2</code> |
|---------------|---|--|
| AArch64 state | <code>DC IVAC</code> , <code>DC CVAC</code> , <code>DC CIVAC</code> | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | <code>DCIMVAC</code> , <code>DCCIMVAC</code> , <code>DCCMVAC</code> | Trapped MCR or MRC access, (coproc==0b1111) using EC value 0x03 |

Note
`DC IVAC` is always UNDEFINED at EL0 using AArch64.
`DCIMVAC`, `DCCIMVAC`, and `DCCMVAC` are always UNDEFINED at EL0 using AArch32.

Table D1-43 Instructions trapped to EL2 when `HCR_EL2.TPU` is 1

| Traps from | Trapped instructions | Syndrome reporting in <code>ESR_EL2</code> |
|---------------|---|--|
| AArch64 state | <code>IC IVAU</code> , <code>IC IALLU</code> , <code>IC IALLUIS</code> , <code>DC CVAU</code> | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | <code>ICIMVAU</code> , <code>ICIALLU</code> , <code>ICIALLUIS</code> , <code>DCCMVAU</code> | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

Note
`IC IALLUIS` and `IC IALLU` are always UNDEFINED at EL0 using AArch64.
`ICIMVAU`, `ICIALLU`, `ICIALLUIS`, and `DCCMVAU` are always UNDEFINED at EL0 using AArch32.

For more information about these instructions, see:

- [Cache maintenance instructions, and data cache zero on page C5-276](#) for the AArch64 instructions.
- [Cache maintenance instructions, functional group on page G4-4201](#) for the AArch32 instructions.

Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register

`HCR_EL2.TACR` traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2:

- 1** Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to EL2.
- 0** Non-secure EL1 accesses to the Auxiliary Control Registers are not trapped to EL2.

Table D1-44 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-44 Register accesses trapped to EL2 when [HCR_EL2.TACR](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|--|
| AArch64 state | ACTLR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | ACTLR and, if implemented, ACTLR2 . | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

———— **Note** —————

- The [ACTLR_EL1](#), [ACTLR](#), and [ACTLR2](#) are not accessible at EL0.
- The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

[HCR_EL2.TIDCP](#) traps the execution of System register access instructions that access these registers, as follows:

- At Non-secure EL1, any attempt to execute a System register access instruction with a reserved register encoding is trapped to EL2.
At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute System register access instructions with reserved register encodings are:
 - Trapped to EL2.
 - UNDEFINED, and any resulting exception is taken to EL1.
- Non-secure EL0 and EL1 System register access instructions with reserved register encodings are not trapped to EL2.

[Table D1-45](#) shows the register encodings for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-45 Encodings trapped to EL2 when [HCR_EL2.TIDCP](#) is 1

| Traps from | Register encodings | Syndrome reporting in ESR_EL2 |
|---------------|--|--|
| AArch64 state | Any access to any of the encodings described in <i>Reserved encodings for IMPLEMENTATION DEFINED registers</i> on page C5-291. | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | An access to any of the following encodings: <ul style="list-style-type: none"> • CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}. • CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}. • CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}. | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

———— **Note** —————

- ARM expects the trapping of Non-secure EL0 accesses to these functions to EL2 to be unusual, and used only when the hypervisor is virtualizing EL0 operation. ARM strongly recommends that unless the hypervisor must virtualize EL0 operation, a Non-secure EL0 access to any of these functions is UNDEFINED, as it would be if the implementation did not include EL2. The PE then takes any resulting exception to Non-secure EL1.

- The trapping of accesses to these registers from Non-secure EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

Traps to EL2 of Non-secure EL1 execution of SMC instructions

[HCR_EL2.TSC](#) traps Non-secure EL1 execution of SMC instructions to EL2:

- 1** Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of [SCR_EL3.SMD](#).
- 0** Non-secure EL1 execution of SMC instructions is not trapped to EL2.

If EL3 is not implemented, [HCR_EL2.TSC](#) is RES0.

[Table D1-46](#) shows how the exceptions are reported in [ESR_EL2](#):

Table D1-46 SMC Instruction trapped to EL2 when [HCR_EL2.TSC](#) is 1

| Traps from | Trapped instruction | Syndrome reporting in ESR_EL2 |
|---------------|-------------------------------------|---|
| AArch64 state | SMC | Trapped SMC instruction execution in AArch64 state, using EC value 0x17 |
| AArch32 state | SMC on page F5-2983 | Trapped SMC instruction execution in AArch32 state, using EC value 0x13 |

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

For more information about SMC instructions, see [SMC on page C6-675](#).

———— **Note** ————

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are UNDEFINED at EL0.
- [HCR_EL2.TSC](#) traps execution of the SMC instruction. It is not a routing control for the SMC exception. Trap exceptions and SMC exceptions have different preferred return addresses.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers

Other than the [MIDR_EL1](#), [MPIDR_EL1](#), and [PMCR_EL0.N](#), the ID registers are divided into groups, with a trap control in the [HCR_EL2](#) for each group.

Table D1-47 ID register groups

| Trap control | Register group |
|------------------------------|--|
| HCR_EL2.TID0 | <i>ID group 0, Primary device identification registers on page D1-1579</i> |
| HCR_EL2.TID1 | <i>ID group 1, Implementation identification registers on page D1-1580</i> |
| HCR_EL2.TID2 | <i>ID group 2, Cache identification registers on page D1-1580</i> |
| HCR_EL2.TID3 | <i>ID group 3, Detailed feature identification registers on page D1-1580</i> |

These controls trap register accesses to EL2, as follows:

[HCR_EL2.TID0](#)

- 0** This control has no effect on Non-secure EL1 reads of the ID group 0 registers.

1 Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to EL2.

HCR_EL2.TID1

0 This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
1 Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to EL2

HCR_EL2.TID2

0 This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.
1 Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the [CSSELR](#) or [CSSELR_EL1](#), is trapped to EL2.

HCR_EL2.TID3

0 This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
1 Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to EL2.

For the [MIDR_EL1](#) and [MPIDR_EL1](#), and for [PMCR_EL0.N](#), the architecture provides read/write aliases. The original register becomes accessible only from EL2 or Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

Table D1-48 ID register substitution

| Register | Original | Alias, EL2 using AArch64 |
|---------------------------------------|----------------------------|-------------------------------|
| Main ID | MIDR_EL1 | VPIDR_EL2 |
| Multiprocessor Affinity | MPIDR_EL1 | VMPIDR_EL2 |
| Performance Monitors Control Register | PMCR_EL0.N | MDCR_EL2.HPMN |

Reads of the [MIDR_EL1](#), [MPIDR_EL1](#) or [PMCR_EL0.N](#) from EL2 or Secure state are unchanged by the implementation of EL2, and access the physical registers.

Note

- If the optional Performance Monitors Extension is not implemented, [MDCR_EL2.HPMN](#) is RES0 and [PMCR_EL0](#) is reserved.
- [MDCR_EL2.HPMN](#) also affects whether a Performance Monitors counter can be accessed from Non-secure EL0 or EL1. See the register description of [MDCR_EL2](#) for more information.
- [PMCR_EL0](#) contains other fields that identify the implementation. For more information about trapping accesses to the [PMCR_EL0](#), see *Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page D1-1588.

ID group 0, Primary device identification registers

In:

- AArch64 state, there are no ID group 0 registers.
- AArch32 state, these registers identify some top-level implementation choices.

Table D1-49 shows the registers that are in ID group 0 for traps to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-49 ID group 0 registers

| Traps from | Group 0 registers | Syndrome reporting in ESR_EL2 |
|---------------|-------------------|--|
| AArch64 state | n/a | n/a |
| AArch32 state | FPSID | Trapped VMRS System register access, using EC value 0x08 |
| | JIDR | Trapped MRC System register access (coproc==0b1110), using EC value 0x05 |

Note

The FPSID is not accessible from EL0 using AArch32.

When the FPSID is accessible, a T32 or A32 VMRS FPSID, <Rt> instruction is permitted but is ignored. The execution of this VMRS instruction execution is not trapped by the ID group 0 trap.

ID group 1, Implementation identification registers

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

Table D1-50 shows the registers that are in ID group 1 for traps to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-50 ID group 1 registers

| Traps from | Group 1 registers | Syndrome reporting in ESR_EL2 |
|---------------|----------------------------|---|
| AArch64 state | REVIDR_EL1, AIDR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | TCMTR, TLBTR, REVIDR, AIDR | Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03 |

ID group 2, Cache identification registers

These registers describe and control the cache implementation.

Table D1-51 shows the registers that are in ID group 2 for traps to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-51 ID group 2 registers

| Traps from | Group 2 registers | Syndrome reporting in ESR_EL2 |
|---------------|--|---|
| AArch64 state | CTR_EL0, CCSIDR_EL1, CLIDR_EL1, CSSELR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | CTR, CCSIDR, CLIDR, CSSELR | Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03 |

ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

Note

In AArch32 state, these registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme on page G4-4195*.

Table D1-52 shows the registers that are in ID group 3 for traps to EL2, and how the exceptions are reported in ESR_EL2.

Table D1-52 ID group 3 registers

| Traps from | Group 3 registers | Syndrome reporting in ESR_EL2 |
|---------------|--|--|
| AArch64 state | <p>ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, and ID_MMFR4_EL1, except that if ID_MMFR4_EL1 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.</p> <p>ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1.</p> <p>MVFR0_EL1, MVFR1_EL1, MVFR2_EL1.</p> <p>ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64AFR0_EL1, ID_AA64AFR1_EL1.</p> <p>It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRS accesses to registers in the following range that are not already mentioned in this table:</p> <ul style="list-style-type: none"> Op0 == 3, CRn == c0, op1 == 0, CRm == {c2-c7}, op2 == {0-7}. | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | <p>MVFR0, MVFR1, MVFR2.</p> <hr/> <p>ID_PFR0, ID_PFR1, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3 and, ID_MMFR4, except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped.</p> <p>ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5.</p> <p>Any MRC access to any of the following encodings in the (coproc==0b1111) encoding space:</p> <ul style="list-style-type: none"> CRn == c0, opc1 == 0, CRm == {c3-c7}, opc2 == {0, 1}. CRn == c0, opc1 == 0, CRm == c3, opc2 == 2. CRn == c0, opc1 == 0, CRm == c5, opc2 == {4, 5}. <p>It is IMPLEMENTATION DEFINED whether HCR_EL2.TID3 traps MRC accesses to in the (coproc==0b1111) encoding space in the following range that are not already mentioned in this table:</p> <ul style="list-style-type: none"> CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}. | <p>Trapped VMRS System register access, using EC value 0x08</p> <hr/> <p>Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03</p> |

Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions

HCR_EL2.{TWE, TWI} trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to EL2:

HCR_EL2.TWE

- | | |
|----------|--|
| 1 | Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state. |
| 0 | Non-secure EL0 or EL1 execution of WFE instructions is not trapped to EL2. |

HCR_EL2.TWI

- 1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** Non-secure EL0 or EL1 execution of WFI instructions is not trapped to EL2.

Table D1-53 shows how the exceptions are reported in [ESR_EL2](#).

Table D1-53 Instructions trapped to EL2 when HCR_EL2.{TWE, TWI} are 1

| Trap control | Traps from | Trapped instructions | Syndrome reporting in ESR_EL2 |
|-----------------------------|-----------------------|----------------------|---|
| HCR_EL2.TWE | Both Execution states | WFE | Trapped WFI or WFE instruction, using EC value 0x01 |
| HCR_EL2.TWI | | WFI | |

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event on page D1-1599](#).
- [Wait For Interrupt on page D1-1602](#).

Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR

[CPTR_EL2.TCPAC](#) traps Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#) to EL2:

- 1** Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#) are trapped to EL2.
- 0** Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#) are not trapped to EL2.

Table D1-54 shows how the exceptions are reported in [ESR_EL2](#).

Table D1-54 Register accesses trapped to EL2 when CPTTR_EL2.TCPAC is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---------------------------|---|
| AArch64 state | CPACR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | CPACR | Trapped MCR or MRC System register access (coproc==0b1111), using EC value 0x03 |

———— **Note** —————

- The [CPACR_EL1](#) or [CPACR](#) is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one function of the [CPACR](#) is as an ID register that identifies what coprocessor or conceptual coprocessor functionality is implemented. Legacy software might use this identification mechanism, and a hypervisor can use this trap to emulate this mechanism. For more information about this coprocessor model see [Background to the System register interface on page G1-3879](#).

General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers

[CPTR_EL2](#).TFP traps Non-secure accesses to SIMD and floating-point registers to EL2:

- 1 . Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL2.
- 0 . Non-secure execution of instructions that access the SIMD or floating-point registers is not trapped to EL2.

[Table D1-55](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-55 Register accesses trapped to EL2 when [CPTR_EL2](#).TFP is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|--|
| AArch64 state | FPCR , FPSR , FPEXC32_EL2 , and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1508. | Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1 .FPEN or CPTR_ELx .TFP, using EC value 0x07 |
| AArch32 state | FPSID , MVFR0 , MVFR1 , MVFR2 , FPSCR , FPEXC , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-3882. | Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1 .FPEN or CPTR_ELx .TFP, using EC value 0x07 ^a |

- a. Permitted VMSR accesses to the [FPSID](#) are ignored, but for the purposes of this trap the architecture defines a VMSR access to the [FPSID](#) from EL1 or higher as an access to a SIMD and floating-point register.

Traps to EL2 of Non-secure System register accesses to the trace registers

[CPTR_EL2](#).TTA traps System register accesses to the trace registers to EL2. These traps are from Non-secure state, so are from all of:

- EL2.
- Non-secure EL0 and EL1.

When [CPTR_EL2](#).TTA is:

- 1 Non-secure System register accesses to the trace registers are trapped to EL2.
- 0 Non-secure System register accesses to the trace registers are not trapped to EL2.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a [CPTR_EL2](#).TTA Trap exception.
- EL2 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page D1-1563.

Table D1-56 shows the registers for which accesses are trapped to EL2 when CPTR_EL2.TTA is 1, and how the exceptions are reported in ESR_EL2.

Table D1-56 Register accesses trapped to EL2 when CPTR_EL2.TTA is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---------------------------------|--|
| AArch64 state | All implemented trace registers | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. |
| AArch32 state | All implemented trace registers | <ul style="list-style-type: none"> Trapped MCR or MRC System register access (coproc==0b1110), using EC value 0x05. Trapped MCRR or MRRC System register access (coproc==0b1110), using EC value 0x0C. |

General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only

HSTR_EL2.{T0-T3, T5-T13, T15} trap accesses to the AArch32 System registers in the coproc==0b1111 encoding space, by the register number, {c0-c3, c5-c13, c15} used for:

- The CRn argument used when accessing the register using an MCR or MRC instruction.
- The CRm argument used when accessing the register using an MCRR or MRRC instruction.

These traps are from AArch32 state only. They are from both:

- Non-secure EL1 using AArch32.
- Non-secure EL0 using AArch32.

When an HSTR_EL2.Tx trap control is:

- 1** Any AArch32 state Non-secure EL1 or EL0 access to the corresponding register is trapped to EL2.
- 0** AArch32 state Non-secure EL1 or EL0 accesses to the corresponding register are not trapped to EL2.

Table D1-57 shows the accesses that are trapped, and how the exceptions are reported in ESR_EL2.

Table D1-57 Accesses trapped to EL2 when an HSTR_EL2.Tx trap is enabled

| Traps from | Trapped accesses | Syndrome reporting in ESR_EL2 |
|---------------|--|---|
| AArch64 state | n/a | n/a |
| AArch32 state | MCR and MRC instructions, where CRn in the instruction identifies the trapped encodings in the (coproc==0b1111) encoding space | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |
| | MCRR and MRRC instructions, where CRm in the instruction identifies the trapped encodings in the (coproc==0b1111) encoding space | Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |

Note

HSTR_EL2[4, 14] is reserved, RES0. Although the Generic Timer AArch32 System registers are implemented in the coproc==0b1111 encoding space and accessed using a CRn or CRm value of c14, EL2 does not provide a trap on accesses to the Generic Timer System registers.

System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from EL0

For an AArch32 System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a HSTR_EL2.Tn control, if an access to the register from EL0 is UNDEFINED when the value of the corresponding HSTR_EL2.Tn trap control is 0, then when that HSTR_EL2.Tn trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure EL0 using AArch32:

- Generates a Trap exception that is taken to EL2.
- Is UNDEFINED and generates an exception that is taken to Non-secure EL1.

If the instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1, and Non-secure EL1 is using AArch64, the exception is reported in ESR_EL1 as an exception for an unknown reason, using EC value 0x00.

———— **Note** —————

ARM expects that trapping to EL2 of Non-secure EL0 accesses to AArch32 System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize EL0 operation. ARM recommends that, whenever possible, Non-secure EL0 accesses to the System registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the Non-secure EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to Non-secure EL1.

Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers

MDCR_EL2.{TDRA, TDOSA, TDA} trap Non-secure System register accesses to the debug registers to EL2, as follows:

- MDCR_EL2.(TDRA, TDA) trap Non-secure EL0 and EL1 accesses.
- MDCR_EL2.TDOSA traps Non-secure EL1 accesses.

———— **Note** —————

EL2 does not provide traps on debug register accesses through the optional memory-mapped external debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL2, no side-effects occur before the exception is taken to EL2. See *Register access instructions on page D1-1563*.

Table D1-58 shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in ESR_EL2.

Table D1-58 Traps of Non-secure EL0 and EL1 accesses to debug registers

| Trap control | Subsection |
|----------------|--|
| MDCR_EL2.TDRA | <i>Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers</i> |
| MDCR_EL2.TDOSA | <i>Trapping System register accesses to powerdown debug registers to EL2 on page D1-1586</i> |
| MDCR_EL2.TDA | <i>Trapping general System register accesses to debug registers to EL2 on page D1-1586</i> |

Trapping System register accesses to Debug ROM registers to EL2

MDCR_EL2.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to EL2:

- | | |
|----------|--|
| 1 | Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2. |
| 0 | Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2. |

This trap applies to Non-secure EL0 only if it is using AArch32.

Table D1-59 shows the register accesses that are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-59 Register accesses trapped to EL2 when [MDCR_EL2.TDRA](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|--|
| AArch64 state | MDRAR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. |
| AArch32 state | DBGDRAR , DBGDSAR | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

If [MDCR_EL2.TDE](#) or [HCR_EL2.TGE](#) is 1, behavior is as if [MDCR_EL2.TDRA](#) is 1 other than for the purpose of a direct read.

Trapping System register accesses to powerdown debug registers to EL2

[MDCR_EL2.TDOSA](#) traps Non-secure EL1 System register accesses to the powerdown debug registers to EL2:

- 1. Non-secure EL1 System register accesses to the powerdown debug registers are trapped to EL2.
- 0. Non-secure EL1 System register accesses to the powerdown debug registers are not trapped to EL2.

Table D1-60 shows the register accesses that are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-60 Register accesses trapped to EL2 when [MDCR_EL2.TDOSA](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|---|
| AArch64 state | OSLAR_EL1 , OSLSR_EL1 , OSDLR_EL1 , DBGPRCR_EL1 . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL2.TDOSA | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. |
| AArch32 state | DBGOSLSR , DBGOSLAR , DBGOSDLR , DBGPRCR . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA | Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. |

Note

These registers are not accessible at EL0.

If [MDCR_EL2.TDE](#) or [HCR_EL2.TGE](#) is 1, behavior is as if [MDCR_EL2.TDOSA](#) is 1 other than for the purpose of a direct read.

Trapping general System register accesses to debug registers to EL2

[MDCR_EL2.TDA](#) traps Non-secure EL0 and EL1 System register accesses to those debug System registers that are not mentioned in either of the following:

- [Traps to EL2 of Non-secure EL0 and EL1 System register accesses to debug registers on page D1-1585.](#)
- [Trapping System register accesses to powerdown debug registers to EL2.](#)

This means that [MDCR_EL2.TDA](#) traps Non-secure EL0 and EL1 System register accesses to all debug System registers to EL2, except the following:

- Any access from:
 - AArch64 state to the [MDRAR_EL1](#).
 - AArch32 state to the [DBGDRAR](#) or [DBGDSAR](#).

MDCR_EL2.TDRA traps these accesses.

- Any access from:
 - AArch64 state to the OSLAR_EL1, OLSR_EL1, OSDLR_EL1 or DBGPRCR_EL1.
 - AArch32 state to the DBGOSLSR, DBGOSLAR, OSDLR_EL1 or DBGPRCR.

MDCR_EL2.TDOSA traps these accesses.

When the PE is in Debug state, MDCR_EL2.TDA does not trap any access from:

- AArch32 state to DBGDTRRXint and DBGDTRTXint.
- AArch64 state to DBGDTR_EL0, DBGDTRRX_EL0, and DBGDTRTX_EL0.

When MDCR_EL2.TDA is:

- | | |
|----------|---|
| 1 | Non-secure EL0 or EL1 System register accesses to any of the registers shown in Table D1-61 are trapped to EL2. |
| 0 | Non-secure EL0 or EL1 System register accesses to the registers shown in Table D1-61 are not trapped to EL2. |

Table D1-61 shows how the exceptions are reported in ESR_EL2.

Table D1-61 Accesses trapped to EL2 when MDCR_EL2.TDA is 1

| Traps from | Trapped accesses | Syndrome reporting in ESR_EL2 |
|---------------|--|---|
| AArch64 state | Accesses to the MDCCSR_EL0, MDCCINT_EL1, DBGDTR_EL0, DBGDTRRX_EL0, DBGDTRTX_EL0, OSDTRRX_EL1, MDSCR_EL1, OSDTRTX_EL1, OSECCR_EL1, DBGBVR<n>_EL1, DBGBCR<n>_EL1, DBGWVR<n>_EL1, DBGWCR<n>_EL1, DBGCLAIMSET_EL1, DBGCLAIMCLR_EL1, and DBGAUTHSTATUS_EL1. | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | Accesses to the DBGDIDR, DBGDSCRint, DBGDCCINT, DBGDTRRXint, DBGDTRTXint, DBGWFAR, DBGVCR, DBGDSCRExt, DBGDTRTXext, DBGDTRRXext, DBGBVR<n>, DBGBCR<n>, DBGXVR<n>, DBGWCR<n>, DBGWVR<n>, DBGCLAIMSET, DBGCLAIMCLR, DBGAUTHSTATUS, DBGDEVID, DBGDEVID1, DBGDEVID2, and DBGSECCR. | For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 |
| | STC accesses to DBGDTRRXint. LDC accesses to DBGDTRTXint. | Trapped LDC or STC access, using EC value 0x06 |

If MDCR_EL2.TDE or HCR_EL2.TGE is 1, behavior is as if MDCR_EL2.TDA is 1 other than for the purpose of a direct read.

Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers

CNTHCTL_EL2.{EL1PCEN, EL1PCTEN} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to EL2, as follows:

- CNTHCTL_EL2.EL1PCEN traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- CNTHCTL_EL2.EL1PCTEN traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- | | |
|----------|---|
| 1 | Non-secure EL0 and EL1 accesses are not trapped to EL2. |
| 0 | Non-secure EL0 and EL1 accesses are trapped to EL2. |

Table D1-62 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-62 Register accesses trapped to EL2 by [CNTHCTL_EL2](#) trap controls

| Traps from | Trap control | Registers | Syndrome reporting in ESR_EL2 |
|---------------|--------------|---|--|
| AArch64 state | EL1PCEN | CNTP_CTL_EL0 , CNTP_CVAL_EL0 , CNTP_TVAL_EL0 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| | EL1PCTEN | CNTPCT_EL0 | |
| AArch32 state | EL1PCEN | CNTP_CTL , CNTP_CVAL , CNTP_TVAL | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 MCR or MRRC instructions, trapped MCR or MRRC access (coproc==0b1111), using EC value 0x04 |
| | EL1PCTEN | CNTPCT | |

Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers

[MDCR_EL2](#).{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to EL2:

[MDCR_EL2.TPM](#)

- 1** Non-secure EL0 and EL1 accesses to the Performance Monitors registers are trapped to EL2.
- 0** Non-secure EL0 and EL1 accesses to the Performance Monitors registers are not trapped to EL2.

[MDCR_EL2.TPMCR](#)

- 1** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are trapped to EL2.
- 0** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers are not trapped to EL2.

———— **Note** —————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

For:

- [MDCR_EL2.TPM == 1](#), [Table D1-63 on page D1-1589](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

- [MDCR_EL2.TPMCR == 1](#), [Table D1-64](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL2](#).

Table D1-63 Register accesses trapped to EL2 when [MDCR_EL2.TPM](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|---|--|
| AArch64 state | PMCR_EL0 , PMCNTENSET_EL0 , PMCNTENCLR_EL0 , PMOVSCLR_EL0 , PMSWINC_EL0 , PMSELR_EL0 , PMCEID0_EL0 , PMCEID1_EL0 , PMCCNTR_EL0 , PMXEVTYPER_EL0 , PMXEVCNTR_EL0 , PMUSERENR_EL0 , PMINTENSET_EL1 , PMINTENCLR_EL1 , PMOVSSET_EL0 , PMEVCNTR<n>_EL0 , PMEVTYPER<n>_EL0 , PMCCFILTR_EL0 . | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | PMCR , PMCNTENSET , PMCNTENCLR , PMOVS , PMSWINC , PMSELR , PMCEID0 , PMCEID1 , PMCCNTR , PMXEVTYPER , PMXEVCNTR , PMUSERENR , PMINTENSET , PMINTENCLR , PMOVSSET , PMEVCNTR<n> , PMEVTYPER<n> , PMCCFILTR . | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 • MCRR or MRRC instructions, trapped MCRR or MRRC access, (coproc==0b1111) using EC value 0x04 |

Table D1-64 Register accesses trapped to EL2 when [MDCR_EL2.TPMCR](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL2 |
|---------------|--------------------------|--|
| AArch64 state | PMCR_EL0 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | PMCR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

———— **Note** —————

[MDCR_EL2.HPMN](#) affects whether a counter can be accessed from Non-secure EL0 or EL1. See the register description of [MDCR_EL2](#) for more information.

D1.15.4 EL3 configurable controls

These controls are in [_EL3](#) System registers. The resulting exceptions might be taken from either Execution state. [SPSR_EL3.M\[4\]](#) indicates which Execution state the exception was taken from.

[Table D1-65](#) shows the [_EL3](#) System registers that contain these controls.

Table D1-65 [_EL3](#) registers that contain instruction enables and disables, and trap controls

| Register description | Register name |
|---|--------------------------|
| Secure Configuration Register | SCR_EL3 |
| Architectural Feature Trap Register, EL3 | CPTR_EL3 |
| Monitor Debug Configuration Register, EL3 | MDCR_EL3 |

Table D1-66 summarizes the controls.

Table D1-66 Instruction enables and disables, and trap controls, provided by EL3

| Control | Control type ^a | Description |
|-----------------------|---------------------------|--|
| SCR_EL3.{TWE, TWI} | T | Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1591 |
| SCR_EL3.ST | T | Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-1592 |
| SCR_EL3.HCE | E | Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1592 |
| SCR_EL3.SMD | D | Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1593 |
| CPTR_EL3.TCPAC | T | Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1593 |
| CPTR_EL3.TTA | T | Traps to EL3 of all System register accesses to the trace registers on page D1-1594 |
| CPTR_EL3.TFP | T | Traps to EL3 of all accesses to the SIMD and floating-point registers on page D1-1594 |
| MDCR_EL3.{TDOSA, TDA} | T | Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers on page D1-1595 |
| MDCR_EL3.TPM | T | Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1597 |

a. See Table D1-67.

Table D1-67 Control types, for exceptions taken to EL1

| Abbreviation | Type | See |
|--------------|---------|--|
| D | Disable | Instruction enables and instruction disables on page D1-1562 |
| E | Enable | Instruction enables and instruction disables on page D1-1562 |
| T | Trap | Trap controls on page D1-1562 |

Also see the following for more general information about traps to EL3:

- Register access instructions on page D1-1563.
- Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32.

Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32

If EL1 is using AArch32, all of the following are trapped to EL3:

- Secure EL1 reads and writes to any of the SCR, NSACR, MVBAR or SDCR.
- Any attempt at Secure EL1 to execute any of the following:
 - AT512NS0xx instructions.
 - SRS instructions that use the R13_mon banked register.
 - MRS or MSR instructions that access any of the SPSR_mon, R13_mon or R14_mon banked registers.

In addition, if EL1 is using AArch32:

- Secure EL1 write accesses to the CNTFRQ register are UNDEFINED. They are not trapped to EL3.

- Any attempt at Secure EL1 to change the mode to Monitor mode, by using a CPS or an MSR instruction, or by performing an exception return, is treated as an illegal change of the **CPSR.M** field. See *Illegal changes to PSTATE.M* on page G1-3809.

Table D1-68 shows the accesses that are trapped to EL3, and how the exceptions are reported in **ESR_EL3**.

Table D1-68 Accesses trapped to EL3 from Secure EL1 using AArch32

| Taken from | Trapped instructions, or trapped accesses | Syndrome reporting in ESR_EL3 |
|--------------------------|---|---|
| Secure EL1 using AArch32 | Reads and writes to any of the SCR , NSACR , MVBAR or SDCR ATS12NS0xx instructions | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |
| | SRS instructions that use the R13_mon banked register | Exception for an unknown reason, using EC value 0x00 |
| | MRS or MSR instructions that accesses any of the SPSR_mon, R13_mon or R14_mon banked registers | |

Note

- Reads of the **NSACR** from either Non-secure EL1 using AArch32 or Non-secure EL2 using AArch32 return the value 0x00000C00. See *Restricted access System registers* on page G4-4156.
- These operations are not available at EL0.

Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions

SCR_EL3.{TWE, TWI} trap EL2, EL1, and EL0 execution of WFE and WFI instructions to EL3:

SCR_EL3.TWE

- 1** Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3.

SCR_EL3.TWI

- 1** Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** EL2, EL1, and EL0 execution of WFI instructions is not trapped.

For EL0 and EL1, these traps apply to WFE and WFI execution in both Security states.

Table D1-69 shows how the exceptions are reported in **ESR_EL3**.

Table D1-69 Instructions trapped to EL3 when **SCR_EL3.{TWE, TWI} are 1**

| Trap control | Traps from | Trapped instructions | Syndrome reporting in ESR_EL3 |
|--------------------|-----------------------|----------------------|---|
| SCR_EL3.TWE | Both Execution states | WFE | Trapped WFI or WFE instruction, using EC value 0x01 |
| SCR_EL3.TWI | | WFI | |

In AArch32 state, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait for Event mechanism and Send event on page D1-1599.](#)
- [Wait For Interrupt on page D1-1602.](#)

Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers

[SCR_EL3.ST](#) traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3:

- 1** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are not trapped to EL3.
- 0** Secure EL1 accesses to the Counter-timer Physical Secure timer registers are trapped to EL3.

Note

Accesses to the Counter-timer Physical Secure timer registers are always enabled at EL3.

[Table D1-70](#) shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in [ESR_EL3](#).

Table D1-70 Register accesses trapped to EL3 when [SCR_EL3.ST](#) is 0

| Traps from | Registers | Syndrome reporting in ESR_EL3 |
|---------------|---|--|
| AArch64 state | CNTPS_TVAL_EL1 CNTPS_CTL_EL1 CNTPS_CVAL_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | n/a | n/a |

Note

These registers are not accessible at EL0.

Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions

[SCR_EL3.HCE](#) enables HVC instruction execution at EL1 and above:

- 1** HVC instruction execution is enabled at EL1 and above.
- 0** HVC instructions are UNDEFINED at EL1, EL2, and EL3, and any resulting exception is taken from the current Exception level to the current Exception level.

For EL1, this enable control applies to HVC instructions in Non-secure state only.

If EL2 is not implemented, this bit is RES0.

Note

HVC instructions are always UNDEFINED at EL0.

Table D1-71 shows how the exceptions are reported in **ESR_ELx**.

Table D1-71 Instruction disabled when SCR_EL3.HCE is 0

| Taken from | Disabled instruction | Syndrome reporting in ESR_ELx |
|---------------|----------------------|--|
| AArch64 state | HVC | Exception for an unknown reason, using EC value 0x00 |
| AArch32 state | | |

Disabling EL3, EL2, and EL1 execution of SMC instructions

SCR_EL3.SMD disables SMC instruction execution at EL1 and above:

- 1** SMC instructions are UNDEFINED at EL1 and above, and any resulting exception is taken from the current Exception level to the current Exception level.
- 0** SMC instruction execution is enabled at EL1 and above.

For EL1, this disable control applies to SMC instructions in both Security states.

———— **Note** ————

SMC instructions are always UNDEFINED at EL0.

Table D1-72 shows how the exceptions are reported in **ESR_ELx**.

Table D1-72 Exceptions generated when SCR_EL3.SMD is 1

| Taken from | Disabled Instruction | Syndrome reporting in ESR_ELx |
|---------------|----------------------|--|
| AArch64 state | SMC | Exception for an unknown reason, using EC value 0x00 |
| AArch32 state | | |

———— **Note** ————

If HCR_EL2.TSC or HCR.TSC traps attempted EL1 execution of SMC instructions to EL2, that trap has priority over this disable.

Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR

CPTR_EL3.TCPAC traps all of the following to EL3:

- EL2 accesses to the CPTR_EL2 or HCPTR.
- EL2 and EL1 accesses to the CPACR_EL1 or CPACR.

When CPTR_EL3.TCPAC is:

- 1** EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3.
- 0** EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-73 shows how the exceptions are reported in [ESR_EL3](#).

Table D1-73 Register accesses trapped to EL3 when [CPTR_EL3.TCPAC](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL3 |
|---------------|---|--|
| AArch64 state | CPTR_EL2 CPACR_EL1 | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | HCPTR CPACR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

Traps to EL3 of all System register accesses to the trace registers

[CPTR_EL3.TTA](#) traps System register accesses to the trace registers, from all Exception levels, to EL3:

- 1** All System register accesses to the trace registers are trapped to EL3.
- 0** System register accesses to the trace registers are not trapped to EL3.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than a [CPTR_EL3.TTA](#) Trap exception.
- EL3 does not provide traps on trace register accesses through the Memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page D1-1563](#).

For EL0 and EL1, this trap control applies to accesses from both Security states.

[Table D1-74](#) shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in [ESR_EL3](#).

Table D1-74 Register accesses trapped to EL3 when [CPTR_EL3.TTA](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL3 |
|---------------|---------------------------------|--|
| AArch64 state | All implemented trace registers | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18 |
| AArch32 state | All implemented trace registers | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. • MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

Traps to EL3 of all accesses to the SIMD and floating-point registers

[CPTR_EL3.TFP](#) traps all accesses to SIMD and floating-point registers, from all Exception levels, to EL3:

- 1** Any attempt at any Exception level to execute an instruction that accesses the SIMD or floating-point registers is trapped to EL3
- 0** Execution of instructions that access the SIMD or floating-point registers is not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-75 shows the registers for which accesses are trapped to EL3, and how the exceptions are reported in ESR_EL3.

Table D1-75 Register accesses trapped to EL3 when CPTR_EL3.TFP is 1

| Traps from | Registers | Syndrome reporting in ESR_EL3 |
|---------------|---|--|
| AArch64 state | FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers. See <i>The SIMD and floating-point registers, V0-V31</i> on page D1-1508. | Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07 |
| AArch32 state | FPSID, MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See <i>Advanced SIMD and floating-point System registers</i> on page G1-3882. | Trapped access to a SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP, using EC value 0x07 ^a |

- a. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.

———— **Note** —————

- FPEXC32_EL2 is not accessible from EL0 using AArch64.
- FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

Traps to EL3 of EL2, EL1, and EL0 System register accesses to debug registers

MDCR_EL3.{TDOSA, TDA} trap EL2, EL1, and EL0 System register accesses to the debug registers to EL3, from both Security states.

———— **Note** —————

EL3 does not provide traps on debug register accesses through the Memory-mapped or External debug interfaces.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to EL3, no side-effects occur before the exception is taken to EL3. See *Register access instructions on page D1-1563*.

Table D1-76 shows the subsections that list the accesses trapped.

Table D1-76 Traps of EL2, EL1, and EL0 accesses to debug registers

| Trap control | Subsection |
|----------------|--|
| MDCR_EL3.TDOSA | <i>Trapping System register accesses to powerdown debug registers to EL3</i> |
| MDCR_EL3.TDA | <i>Trapping general System register accesses to debug registers to EL3 on page D1-1596</i> |

Trapping System register accesses to powerdown debug registers to EL3

MDCR_EL3.TDOSA traps EL2 and EL1 accesses to the powerdown debug registers to EL3:

- 1** EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3.
0 EL2 and EL1 System register accesses to the powerdown debug registers are not trapped to EL3.

For EL1, this trap control applies to accesses from both Security states.

Table D1-77 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL3](#).

Table D1-77 Register accesses trapped to EL3 when [MDCR_EL3.TDOSA](#) is 1

| Traps from | Registers | Syndrome reporting in ESR_EL3 |
|---------------|--|--|
| AArch64 state | OSLAR_EL1 , OSLSR_EL1 , OSDLR_EL1 , DBGPRCR_EL1 . Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by MDCR_EL3.TDOSA . | Trapped AArch64 MSR, MRS, or system instruction, using EC value 0x18. |
| AArch32 state | DBGOSLSR , DBGOSLAR , DBGOSDLR , DBGPRCR . | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

———— **Note** —————

These registers are not accessible at EL0.

Trapping general System register accesses to debug registers to EL3

[MDCR_EL3.TDA](#) traps EL2, EL1, and EL0 System register accesses to the debug System registers that are not mentioned in [Trapping System register accesses to powerdown debug registers to EL3](#) on page D1-1599.

This means that [MDCR_EL3.TDA](#) traps EL2, EL1, and EL0 System register accesses to all debug System registers, except the following:

- Accesses from AArch64 state to the [OSLAR_EL1](#), [OSLSR_EL1](#), [OSDLR_EL1](#) or [DBGPRCR_EL1](#).
- Accesses from AArch32 state to the [DBGOSLSR](#), [DBGOSLAR](#), [OSDLR_EL1](#) or [DBGPRCR](#).

When [MDCR_EL3.TDA](#) is:

- 1** EL2, EL1, and EL0 System register accesses to any of the registers shown in [Table D1-78](#) on page D1-1601 are trapped to EL3.
- 0** EL2, EL1, and EL0 System register accesses to the registers shown in [Table D1-78](#) on page D1-1601 are not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

When the PE is in Debug state, [MDCR_EL3.TDA](#) does not trap any access from:

- AArch32 state to [DBGDTRRXint](#) and [DBGDTRTXint](#).
- AArch64 state to [DBGDTR_EL0](#), [DBGDTRRX_EL0](#), and [DBGDTRTX_EL0](#).

Table D1-78 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL3](#).

Table D1-78 Accesses trapped to EL3 when [MDCR_EL3.TDA](#) is 1

| Traps from | Trapped accesses | Syndrome reporting in ESR_EL3 |
|---------------|---|--|

Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers

[MDCR_EL3.TPM](#) traps EL2, EL1, and EL0 accesses to the Performance Monitors registers to EL3:

- 1** EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3.
- 0** EL2, EL1, and EL0 System register accesses to Performance Monitors registers are not trapped to EL3.

For EL0 and EL1, this trap control applies to accesses from both Security states.

Table D1-79 shows the registers for which accesses are trapped, and how the exceptions are reported in [ESR_EL3](#).

Table D1-79 Register accesses trapped to EL3 when [MDCR_EL3.TPM](#) is 1

D1.16 System calls

A system call is generated by the execution of an SVC, HVC, or SMC instruction:

- By default, the execution of an SVC instruction generates a Supervisor Call, a synchronous exception that targets EL1. This provides a mechanism for software executing at EL0 to make a call to an operating system or other software executing at EL1.
- In an implementation that includes EL2, the execution of an HVC instruction generates a Hypervisor Call, a synchronous exception that targets EL2 by default.

The HVC instruction is UNDEFINED:

- At EL0.
- At EL1 in Secure state.

———— **Note** —————

Software executing at EL0 cannot directly generate a Hypervisor Call.

- In an implementation that includes EL3, by default the execution of an SMC instruction generates a Secure Monitor Call, a synchronous exception that targets EL3.

The SMC instruction is UNDEFINED at EL0, meaning software executing at EL0 cannot directly generate a Secure Monitor Call.

The default behavior applies when the instruction is not UNDEFINED and both of the following are true:

- The instruction is executed at an Exception level that is the same as or lower than the target Exception level.
- The instruction is not trapped to a different Exception level.

If an SVC or HVC instruction is executed at an Exception level that is higher than the target Exception then it generates a synchronous exception that is taken to the current Exception level.

EL2 and EL3 can disable Hypervisor Call exceptions, see:

- [Disabling Non-secure state execution of HVC instructions on page D1-1574.](#)
- [Enabling EL3, EL2, and Non-secure EL1 execution of HVC instructions on page D1-1592.](#)

EL2 can trap use of the SMC instruction, see [Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578.](#)

EL3 can disable Secure Monitor Call exceptions, see [Disabling EL3, EL2, and EL1 execution of SMC instructions on page D1-1593.](#)

D1.16.1 Pseudocode description of system calls

The `AArch64.CallSupervisor()` pseudocode function performs an SVC call in AArch64 state.

The `AArch64.CallHypervisor()` pseudocode function performs an HVC call in AArch64 state.

The `AArch64.CallSecureMonitor()` pseudocode function performs an SMC call in AArch64 state.

The `AArch64.CallSupervisor()`, `AArch64.CallHypervisor()`, and `AArch64.CallSecureMonitor()` functions are described in [Chapter J1 ARMv8 Pseudocode.](#)

D1.17 Mechanisms for entering a low-power state

The ARM architecture provides mechanisms that software can use to indicate that the PE can enter a low-power state, if it supports that state. The following sections describe those mechanisms:

- [Wait for Event mechanism and Send event.](#)
- [Wait For Interrupt](#) on page D1-1602.

D1.17.1 Wait for Event mechanism and Send event

A PE can use the *Wait for Event* (WFE) mechanism to enter a low-power state, depending on the value of an Event Register for that PE. To enter the low-power state, the PE executes a Wait For Event instruction, WFE, and if the Event Register is clear, the PE can enter the low-power state.

If the PE does enter the low-power state, it remains in that low-power state until it receives a *WFE wake-up event*.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFE instruction must not cause a loss of memory coherency.

WFE mechanism behavior depends on the interaction of all of the following, that are described in the subsections that follow:

- The Event Register for the PE. See subsection [The Event Register](#) on page D1-1600.
- The Wait For Event instruction, WFE. See subsection [The Wait For Event instruction](#) on page D1-1600.
- *WFE wake-up events*. See subsection [WFE wake-up events in AArch64 state](#) on page D1-1601
- The Send Event instructions, SEV and SEVL that can cause WFE wake-up events. See subsection [The Send Event instructions](#) on page D1-1601.

———— Note —————

Because the Wait for Event mechanism is associated with suspending execution on a PE for the purpose of power saving, ARM recommends that the Event Register is set only infrequently. However, software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

[Example D1-2](#) describes how a spinlock implementation might use the WFE mechanism to save energy.

Example D1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device, it might need to add data received from the device to a queue. If another PE is removing data from the same queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the second PE has released the lock. The first PE cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores](#) on page B2-108.
- If the PE obtains the lock it performs its memory operation and then releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. When the lock becomes available, the PE again attempts to obtain it.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multiprocessor system the execution of spin-locks by multiple waiting PEs can degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock:

- A PE that fails to obtain a lock executes a WFE instruction to request entry to a low-power state, at the time when the exclusive monitor is set holding the address of the location holding the lock.
- When a PE releases a lock, the write to the lock location causes the exclusive monitor of any PE monitoring the lock location to be cleared. This clearing of the exclusive monitors generates a WFE wake-up event for each of those PEs. Then, these PEs can attempt to obtain the lock again.

For large systems, more advanced locking systems, such as ticket locks, can avoid unfairness caused by having multiple PEs simultaneously reading the lock. In such systems, the WFE mechanism can be used in a similar way to monitor the next ticket value.

The Event Register

The Event Register is a single bit register for each PE. When set, an Event Register indicates that an event has occurred since the register was last cleared, that might require some action by the PE. Therefore, when the Event Register is set, the PE must not suspend operation on executing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see [Event streams on page D6-1882](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

The Event Register is cleared only by a Wait For Event instruction.

Note

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction, WFE, depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately.
- If the Event Register is clear the PE can suspend execution and enter a low-power state. It remains in that state until the PE detects a WFE wake-up event, or earlier if the implementation chooses, or a until a reset. When the PE detects a WFE wake-up event, or earlier if chosen, the WFE instruction completes. If the wake-up event sets the Event Register, it is IMPLEMENTATION DEFINED whether on restarting execution, the Event Register is cleared.

The WFE instruction is available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1565](#).
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1581](#).
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1591](#).

Note

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake-ups.

WFE wake-up events in AArch64 state

The following are *WFE wake-up events*:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by [EDSCR.INTdis](#) and:
 - Is marked as **A** in the tables in *Asynchronous exception masking* on page D1-1557, regardless of the value of the corresponding [PSTATE.{A, I, F}](#) mask bit.
 - Is marked as **B** in the tables in *Asynchronous exception masking* on page D1-1557, if the value of the corresponding [PSTATE.{A, I, F}](#) mask bit is 0.
- In Non-secure EL1 or ELO, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is not disabled by [EDSCR.INTdis](#) and is marked as **B** in [Table D1-18](#) on page D1-1559 in *Virtual interrupts* on page D1-1558, if the value of the corresponding [PSTATE.{A, I, F}](#) mask bit is 0.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see *Halting allowed and halting prohibited* on page H2-4845.
See also *External Debug Request debug event* on page H3-4900.
- An event sent by the timer event stream for the PE. See *Event streams* on page D6-1882.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Not all of these wake-up events set the Event Register.

Note

The disabling of interrupts, and WFE wake-up events, by [EDSCR.INTdis](#) is possible only when external debug is enabled.

The Send Event instructions

The Send Event instructions are:

SEV, Send Event This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local

This must set the local Event Register.

Note

It might signal an event to other PEs by some IMPLEMENTATION DEFINED mechanism, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

Note

A DSB instruction ensures that no instructions, including any SEV instructions, that appear in program order after the DSB instruction, can execute until the DSB instruction has completed. See [Data Synchronization Barrier \(DSB\) on page B2-89](#).

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

The receipt of a signaled SEV or SEVL event by a PE sets the Event Register on that PE.

The SEV and SEVL instructions are available at all Exception levels.

Pseudocode description of the Wait For Event mechanism

This section identifies pseudocode functions that describe the behavior of the Wait For Event mechanism.

The [ClearEventRegister\(\)](#) pseudocode function clears the Event Register of the current PE.

The [EventRegistered\(\)](#) pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The [WaitForEvent\(\)](#) pseudocode function optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes [ClearEventRegister\(\)](#) to be called.

The [SendEvent\(\)](#) pseudocode function sets the Event Register of every PE in the multiprocessor system.

The [EventRegisterSet\(\)](#) pseudocode function sets the event register for the local PE.

D1.17.2 Wait For Interrupt

Software can use the *Wait for Interrupt (WFI)* instruction to cause the PE to enter a low-power state. The PE then remains in that low-power state until it receives a *WFI wake-up event*, or until some other IMPLEMENTATION DEFINED reason causes it to leave the low-power state. The architecture permits a PE to leave the low-power state for any reason, but requires that it must leave the low-power state on receipt of any architected WFI wake-up event.

Note

Because the architecture permits a PE to leave the low-power state for any reason, it is permissible for a PE to treat WFI as a NOP, but this is not recommended for lowest power operation.

When the PE leaves a low-power state that was entered as a result of a WFI instruction, that WFI instruction completes.

The architecture does not define the exact nature of the low-power state, except that the execution of a WFI instruction must not cause a loss of memory coherency.

Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 might be trapped to a higher Exception level. See:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1565](#).
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1581](#).
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1591](#).

WFI wake-up events

The following are *WFI wake-up events*:

- Any physical SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as **A** as **B** in the tables in [Asynchronous exception masking on page D1-1557](#), regardless of the value of the corresponding `PSTATE.{A, I, F}` mask bit.

- In Non-secure EL1 or EL0, any virtual SError interrupt, IRQ interrupt, or FIQ interrupt received by the PE, that is marked as B in Table D1-18 on page D1-1559 in *Virtual interrupts on page D1-1558*, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see *Halting allowed and halting prohibited on page H2-4845*.
See also *External Debug Request debug event on page H3-4900*.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

Note

- WFI wake-up events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.{A, I, F} mask bits. If wake-up is invoked by an interrupt that is disabled or masked the interrupt is not taken.
- Because debug events are WFI wake-up events, ARM recommends that Wait For Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.
- Some implementations of the WFI mechanism drain down any pending memory activity before suspending execution. This increases power saving, by increasing the area over which clocks can be stopped. The architecture does not require this operation, therefore software must not rely on the WFI mechanism operating in this way.

Using WFI to indicate an idle state on bus interfaces

Software can use the WFI mechanism to force quiescence on a PE, and, combined with preventing any possible WFI wakeup events, this can be used to complete an entry into a powerdown state.

Because mechanisms for entering powerdown states are inherently IMPLEMENTATION DEFINED, whether an implementation uses the WFI mechanism is IMPLEMENTATION DEFINED. If it does, the WFI instruction forces the suspension of execution, and of all associated bus activity.

The control logic that does this also tracks the activity on the bus interfaces of the PE, so that when the PE has completed all current operations and any associated bus activity has completed, it can signal to an external power controller that there is no ongoing bus activity.

However, the PE must continue to process memory-mapped and external debug interface accesses to debug registers when in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the OS Double Lock control, `OSDLR_EL1.DLK`, is 1, the PE must not signal this idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see *Debug behavior when the OS Double Lock is locked on page H6-4953*.

Note

In a PE that implements separate core and debug power domains, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see *Power domains and debug on page H6-4945*.

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode description of Wait For Interrupt

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

D1.18 Self-hosted debug

The ARMv8-A architecture supports both of the following:

Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate *debug exceptions*. Debug exceptions are accommodated in the ARMv8-A Exception model.

External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate *Debug events*, that cause the PE to enter *Debug state*. In Debug state, the PE is halted.

This section describes self-hosted debug. It includes:

- [Debug exceptions](#).
- [The PSTATE debug mask bit, D](#).

For external debug, see part E.

D1.18.1 Debug exceptions

Debug exceptions occur during normal program flow, if a debugger has programmed the PE to generate them.

For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

The possible debug exceptions are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

[Chapter D2 AArch64 Self-hosted Debug](#) describes these in detail for AArch64.

For the PE to generate a debug exception requires that:

- The debug exception is enabled. [The debug exception enable controls on page D2-1630](#) gives the controls for the different debug exceptions.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1633](#).

Debug exceptions are synchronous exceptions, and are accommodated in the ARMv8 Exception model.

———— **Note** —————

Breakpoints and Watchpoints can cause entry to Debug state instead of causing debug exceptions. See [Chapter H1 About External Debug](#).

D1.18.2 The PSTATE debug mask bit, D

As with all other exceptions, when a debug exception is taken, software must take care to avoid generating another instance of an exception within the exception handler, to avoid recursive entry into the exception handler and loss of return state.

To help avoid this, the ARMv8 architecture provides a debug exception mask bit, [PSTATE.D](#), that can mask Watchpoint, Breakpoint, and Software Step exceptions when the target Exception level is the current Exception level.

PSTATE.D is set to 1 on taking an exception. This means that while handling an exception in AArch64 state, Watchpoint, Breakpoint, and Software Step exceptions are masked. This prevents recursive entry at the Exception level that debug exceptions are targeted to.

When execution is in AArch64 state, debug exceptions are also masked implicitly when the target Exception level is lower than the current Exception level.

When the target Exception level is higher than the current Exception level, debug exceptions cannot be masked by **PSTATE.D**.

Because debug exceptions are synchronous, the architecture requires that debug exceptions are not generated when **PSTATE.D** is 1. By preventing debug exception generation, debug exceptions cannot be taken at a subsequent time when the Process state D mask bit is cleared to 0.

———— **Note** —————

This differs from the behavior for interrupts, where the **PSTATE.{A, I, F}** mask has the effect of preventing the interrupt from being taken, but instead the interrupt remains pending.

D1.19 The Performance Monitors Extension

The System registers provide access to a Performance Monitors Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE. The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of 32-bit event counters. Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
 - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
 - Implementation-specific events. The PMU specification reserves event numbers for implementation-specific events. See [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#).

For more information, see [Chapter D5 The Performance Monitors Extension](#).

D1.20 Interprocessing

Interprocessing is the term used to describe moving between the AArch64 and AArch32 Execution states.

The Execution state can change only on a change of Exception level. This means that the Execution state can change only on taking an exception to a higher Exception level, or returning from an exception to a lower Exception level.

On taking an exception to a higher Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch32 state to AArch64 state.

On returning from an exception to a lower Exception level, the Execution state either:

- Remains unchanged.
- Changes from AArch64 state to AArch32 state.

Note

If, on taking or returning from an exception, the Exception level remains the same, the Execution state cannot change.

For the description of:

- Exception entry to an Exception level using AArch64, see [Exception entry on page D1-1521](#).
- Exception return from an Exception level using AArch64 state, see [Exception return on page D1-1536](#).
- Exception return to AArch32 state, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

Note

The description in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#) is outside the scope of interprocessing, because such exceptions must have been taken from an Exception level that is using AArch32, and therefore there is no change of Execution state.

The following sections describe the behavior associated with interprocessing.

- [Register mappings between AArch32 state and AArch64 state](#).
- [State of the general-purpose registers on taking an exception to AArch64 state on page D1-1616](#).
- [SPSR, ELR, and AArch64 SP relationships on changing Execution state on page D1-1617](#).

D1.20.1 Register mappings between AArch32 state and AArch64 state

This section defines the architectural mappings between AArch32 state registers and AArch64 state registers.

The mappings describe:

- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

The general model is:

- The AArch32 register contents are situated in the bottom 32 bits of the AArch64 registers.
- In AArch32 state, the upper 32 bits of AArch64 registers are inaccessible and are ignored.

Note

System software that executes in AArch64 state, such as an OS or Hypervisor, can use these mappings for context save and restore, or to interpret and modify the AArch32 registers of an application or virtual machine.

For more information see the following subsections:

- [Mapping of the general-purpose registers between the Execution states.](#)
- [Mapping of the SIMD and floating-point registers between the Execution states on page D1-1609.](#)
- [Mapping of the System registers between the Execution states on page D1-1610.](#)

Mapping of the general-purpose registers between the Execution states

Table D1-80 shows how each of the AArch32 general-purpose registers, R0-R12, SP, and LR, including the banked copies of these registers, maps to an AArch64 general-purpose register. A register in the *AArch64 register* column of the table provides the AArch64 view of the corresponding register in the *AArch32 register* column.

———— **Note** —————

For some exceptions, the exception syndrome given in the `ESR_ELx` identifies one or more register numbers from the issued instruction that generated the exception. Where the exception is taken from an Exception level using AArch32 these register numbers give the AArch64 view of the register. For example, if an exception is taken from AArch32 Abort mode, and the faulting instruction specified R14, the `ESR_ELx.ISS` field would report this using the EC value `0b10100`, because register X20 provides the AArch64 view of LR_abt. which is the copy of R14 used in Abort mode.

Table D1-80 General-purpose register mapping between AArch32 state and AArch64 state

| AArch32 register | AArch64 register |
|------------------|------------------|
| R0 | X0 |
| R1 | X1 |
| R2 | X2 |
| R3 | X3 |
| R4 | X4 |
| R5 | X5 |
| R6 | X6 |
| R7 | X7 |
| R8_usr | X8 |
| R9_usr | X9 |
| R10_usr | X10 |
| R11_usr | X11 |
| R12_usr | X12 |
| SP_usr | X13 |
| LR_usr | X14 |
| SP_hyp | X15 |
| LR_irq | X16 |
| SP_irq | X17 |
| LR_svc | X18 |

Table D1-80 General-purpose register mapping between AArch32 state and AArch64 state

| AArch32 register | AArch64 register |
|-------------------------|-------------------------|
| SP_svc | X19 |
| LR_abt | X20 |
| SP_abt | X21 |
| LR_und | X22 |
| SP_und | X23 |
| R8_fiq | X24 |
| R9_fiq | X25 |
| R10_fiq | X26 |
| R11_fiq | X27 |
| R12_fiq | X28 |
| SP_fiq | X29 |
| LR_fiq | X30 |

Note

For a description of the banking of AArch32 general-purpose registers R8-R12, SP, and LR, see [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#) on page G1-3801.

Mapping of the SIMD and floating-point registers between the Execution states

Table D1-81 shows the mapping between the AArch64 V registers and the AArch32 Q registers.

Table D1-81 SIMD and floating-point register mapping between AArch64 state and AArch32 state

| AArch64 register | AArch32 register |
|-------------------------|-------------------------|
| V0 | Q0 |
| V1 | Q1 |
| V2 | Q2 |
| . | . |
| . | . |
| . | . |
| V15 | Q15 |

The AArch64 registers V16-V31 are not accessible from AArch32 state.

The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state:

- In AArch64 state, there are:
 - 32 128-bit V registers, V0-V31.
 - 32 64-bit D registers, D0-D31.
 - 32 32-bit S registers, S0-S31.

A smaller register occupies the least-significant bytes of the corresponding larger register. For example, S5 is the least-significant word of D5 and V5. [Figure D1-3](#) shows this mapping.

Figure D1-3 AArch64 state SIMD and floating-point register mappings

- In AArch32 state, there are:
 - 16 128-bit Q registers, Q0-Q15.
 - 32 64-bit D registers, D0-D31.
 - 32 32-bit S registers, S0-S31.

Smaller registers are packed into larger registers. [Figure D1-4](#) shows this mapping.

Figure D1-4 AArch32 state SIMD and floating-point register mappings

In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15. For example, D16 and D17 pack into Q8.

Note

A consequence of this mapping is that if software executing in AArch64 state interprets D or S registers from AArch32 state, it must unpack the D or S registers from the V registers before it uses them.

Mapping of the System registers between the Execution states

ARMv8 architecturally defines the relationship between the AArch64 System registers and the AArch32 System registers, to allow supervisory code such as a hypervisor, that is executing in AArch64 state, to save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

Any modifications made to AArch32 System registers affects only those parts of those AArch64 registers that are mapped to the AArch32 System registers. Bits[63:32] of AArch64 registers, where they are not mapped to AArch32 registers, are unchanged by AArch32 state execution.

Note

This model is different to the model for the general-purpose registers described in [Mapping of the general-purpose registers between the Execution states on page D1-1608](#). In this model, there are several cases where two AArch32 System registers are packed into a single AArch64 System register.

When EL3 is implemented and is using AArch32, some System registers are banked between the two Security states. When a register is banked in this way, there is an instance of the register in Secure state, and another instance of the register in Non-secure state. In [Table D1-82 on page D1-1611](#) these banked registers are identified by footnote^a. This banking is not supported when EL3 is using AArch64 or if EL3 is not implemented. This means that when EL3 is implemented and is using AArch64, exactly the same registers are accessed in the following states:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

This means that, architecturally, it is not possible to determine whether an AArch64 register is mapped onto the Secure instance of the corresponding AArch32 register, or onto the Non-secure instance of that register. When EL3 is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt as is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.

———— **Note** ————

Although the architecture does not require this, because it is not architecturally visible, ARM expects that implementations will map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and will map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this is not possible for the following registers:

- IFAR** This is because when EL3 is using AArch32, **HIFAR** is an alias of the Secure **IFAR**.
DFAR This is because when EL3 is using AArch32, **HDFAR** is an alias of the Secure **DFAR**.

Table D1-82 shows the mappings between the writable AArch64 System registers and the AArch32 System registers.

Table D1-82 Mapping of writable AArch64 System registers to the AArch32 System registers

| AArch64 register | AArch32 register |
|----------------------------------|---|

a. AArch32 registers that are banked if EL3 is using AArch32.

b. These registers have overlapping register content. One or more bits of one register appear in the other register.

There are a small number of AArch32 System registers that are not mapped to any AArch64 System registers. The AArch64 registers listed in Table D1-83 can be used to access these from a higher Exception level that is using AArch64. The registers shown in the table are UNDEFINED if EL1 cannot use AArch32.

Table D1-83 AArch64 registers for accessing registers that are only used in AArch32 state

| AArch32 register | AArch64 register for accessing the AArch32 register | Short description |
|------------------|---|---|
| DACR | DACR32_EL2 | Domain Access Control Register |
| DBGVCR | DBGVCR32_EL2 | Debug Vector Catch Register |
| FPEXC | FPEXC32_EL2 | Floating-Point Exception Control Register |
| IFSR | IFSR32_EL2 | Instruction Fault Status Register |
| SDER | SDER32_EL3 | AArch32 Secure Debug Enable Register |

Table D1-84 shows the AArch64 System registers that allow access from AArch64 state to the AArch32 ID registers. These AArch64 registers are UNKNOWN if no Exception level can use AArch32.

Table D1-84 AArch64 registers that access the AArch32 ID registers

| AArch32 register | AArch64 register for accessing the AArch32 register | Short description |
|------------------|---|---|
| ID_AFR0 | ID_AFR0_EL1 | AArch32 Auxiliary Feature Register 0 |
| ID_DFR0 | ID_DFR0_EL1 | AArch32 Debug Feature Register 0 |
| ID_ISAR0 | ID_ISAR0_EL1 | EL1, AArch32 Instruction Set Attribute Register 0 |
| ID_ISAR1 | ID_ISAR1_EL1 | EL1, AArch32 Instruction Set Attribute Register 1 |

| ID_PFR1 | ID_PFR1_EL1 | AArch32 PE Feature Register 1 |

D1.20.2 State of the general-purpose registers on taking an exception to AArch64 state

When an exception is taken from AArch32 state to AArch64 state, the state of a general-purpose register depends on whether, immediately before the exception, the register was accessible from AArch32 state, as follows:

If the general-purpose register was accessible from AArch32 state

The upper 32 bits either become zero, or hold the value that the same architectural register held before any AArch32 execution. The choice between these two options is IMPLEMENTATION DEFINED, and might vary dynamically within an implementation. Correspondingly, software must regard the value as being a CONSTRAINED UNPREDICTABLE choice between these two values.

This behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32. That is, this behavior applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

Which general-purpose registers have their upper 32 bits affected in this way depends on both:

- The AArch64 state target Exception level.
- The values of both:
 - [SCR_EL3.RW](#).
 - [HCR_EL2.RW](#) or [HCR.RW](#), where [HCR.RW](#) is a notional bit that is RES0.

[Table D1-85](#) shows which general-purpose registers can have their upper 32 bits set to zero.

Table D1-85 General-purpose registers that can have their upper 32 bits set to zero on taking an exception to AArch64 state from AArch32 state

| SCR_EL3.RW | HCR_EL2.RW or HCR.RW ^a | Registers when the target Exception level is: | | |
|----------------------------|---|---|-----------------|--------|
| | | EL3 | EL2 | EL1 |
| 0 | 0 | X0-X30 | _b | _b |
| 0 | 1 | _c | _c | _c |
| 1 | 0 | X0-X14, X16-X30 | X0-X14, X16-X30 | _b |
| 1 | 1 | X0-X14 | X0-X14 | X0-X14 |

- a. [HCR.RW](#) is a notional bit that is RES0.
- b. The RW bit values are not valid for the targeted Exception level.
- c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the [SCR_EL3.NS](#) or [SCR.NS](#) bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels on page D1-1621*, the behavior is consistent with [HCR_EL2.RW](#) taking the value of [SCR_EL3.RW](#).

If the general-purpose register was not accessible from AArch32 state

The general rule is that the register retains the state it had before any AArch32 execution.

There is one exception to this rule, that is when taking an exception to EL3 using AArch64 when either EL2 is not implemented or EL1 is in Secure state. In these cases, the X15 register must be treated as if it is accessible when the value of [SCR_EL3.RW](#) is 0, and therefore the upper bits of X15 might either be set to zero or retain their previous value.

Which general-purpose registers retain their state depends on both:

- The AArch64 state target Exception level.
- The values of both:
 - [SCR_EL3.RW](#).

— [HCR_EL2.RW](#) or [HCR.RW](#), where [HCR.RW](#) is a notional bit that is RES0.

[Table D1-86](#) shows which general-purpose registers can retain their state.

Table D1-86 General-purpose registers that can retain their state on taking an exception to AArch64 from AArch32

| SCR_EL3.RW | HCR_EL2.RW or HCR.RW ^a | Registers when the target Exception level is: | | |
|----------------------------|---|---|---------|---------|
| | | EL3 | EL2 | EL1 |
| 0 | 0 | None | _b | _b |
| 0 | 1 | _c | _c | _c |
| 1 | 0 | X15 | X15 | _b |
| 1 | 1 | X15-X30 | X15-X30 | X15-X30 |

- a. [HCR.RW](#) is a notional bit that is RES0.
- b. The RW bit values are not valid for the targeted Exception level.
- c. Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.

Note

If EL2 is not implemented, or the [SCR_EL3.NS](#) bit prevents its use, then as described in *The effects of supporting fewer than four Exception levels on page D1-1621*, the behavior is consistent with [HCR_EL2.RW](#) taking the value of [SCR_EL3.RW](#).

D1.20.3 SPSR, ELR, and AArch64 SP relationships on changing Execution state

[Table D1-87](#) shows the SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state.

Table D1-87 SPSR and ELR mappings between AArch32 state and AArch64 state

| AArch32 register | AArch64 register |
|--------------------------|--------------------------|
| SPSR_svc | SPSR_EL1 |
| SPSR_hyp | SPSR_EL2 |
| ELR_hyp | ELR_EL2 |

On exception entry to EL3 using AArch64 state from an Exception level using AArch32 state, when EL2 has been using AArch32 state, the upper 32-bits of [ELR_EL2](#) are either set to zero or they retain the value before the AArch32 state execution. The implementation determines the choice between these two options, and the choice might vary dynamically within an implementation. Therefore, software must regard the upper 32-bits as being UNKNOWN.

On exception entry to an Exception level using AArch64 state from an Exception level using AArch32 state, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during execution in AArch32 state at that Exception level, retain the state that they had before the execution in AArch32 state.

The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state when there is execution at EL1 with EL1 using AArch64 state:

- [SPSR_abt](#).
- [SPSR_und](#).
- [SPSR_irq](#).

- [SPSR_fiq](#).

———— **Note** —————

- These registers are accessible during execution in AArch64 state at Exception levels higher than EL1, for context switching.
- If EL1 does not support execution in AArch32 state then these registers are RES0.

On exception entry to an Exception level using AArch64 from an Exception level using AArch32, the AArch64 Stack Pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at that Exception level retain the state that they had before AArch32 execution. This applies to the following registers:

- [SP_ELO](#).
- [SP_EL1](#).
- [SP_EL2](#).
- [ELR_EL1](#).

D1.21 The effect of implementation choices on the programmers' model

Three of the implementation choices in ARMv8 are:

- The number of Exception levels implemented.
- Which Exception levels support AArch32 and which Exception levels support AArch64.
- Whether SIMD and floating-point support is implemented.

The following subsections give more information about how these choices affect the programmers' model:

- [Implication of Exception levels implemented.](#)
- [Support for Exception levels and Execution states on page D1-1620.](#)
- [Implementations not including Advanced SIMD and floating-point instructions on page D1-1621.](#)
- [The effects of supporting fewer than four Exception levels on page D1-1621.](#)

D1.21.1 Implication of Exception levels implemented

All implementations must include EL0 and EL1.

EL2 and EL3 are optional. The architecture permits all combinations of EL2 and EL3.

See also [Implementations not including Advanced SIMD and floating-point instructions on page D1-1621](#) and [The effects of supporting fewer than four Exception levels on page D1-1621](#).

For an implementation that includes all of the Exception levels [Figure D1-5](#) shows the implemented Exception levels and the possible Execution states at lower Exception levels when EL3 is using AArch64. [Figure D1-5](#) applies regardless of whether EL3 also supports use of AArch32.

† AArch64 permitted only if EL1 is using AArch64

‡ AArch64 permitted only if EL2 is using AArch64

Figure D1-5 ARMv8-A security model when EL3 is using AArch64

The possible combinations of Exception levels are as follows:

- EL0, EL1, and EL2. The implementation supports only Non-secure state.

- EL0, EL1, and EL3. The implementation does not support Virtualization. The Exception levels and Execution states depend on whether EL3 is using AArch64 state or AArch32 state, as follows:
 - If EL3 is using AArch64, the Exception levels and Execution states are as shown in [Figure D1-5 on page D1-1619](#) with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
 - If EL3 is using AArch32, the Exception levels and Execution states are as shown in [Figure G1-1 on page G1-3790](#) with EL2 removed and no Non-secure state virtualization of EL1 and EL0.
- EL0 and EL1 only. The implementation supports only a single Security state. This might be either Secure state or Non-secure state, see [Behavior when only EL1 and EL0 are implemented on page D1-1622](#).
- EL0, EL1, EL2, and EL3, as described in this section.

For more information, see [The effects of supporting fewer than four Exception levels on page D1-1621](#).

D1.21.2 Support for Exception levels and Execution states

Subject to the interprocessing rules defined in [Interprocessing on page D1-1607](#), an implementation of the ARM architecture could support:

- AArch64 state only.
- AArch64 and AArch32 states.
- AArch32 state only.

This means the ARMv8-A architecture can, potentially, support implementations with very large number of combinations of Execution state and Exception level. ARM intends to license only a subset of the possible combinations. [Table D1-88](#) shows the combinations of Exception levels and Execution states that are currently licensed.

Table D1-88 Supported combinations of Exception levels and Execution state

| Number of Exception levels | Supported Security states | Exception levels, AArch64 state | | | | Exception levels, AArch32 state | | | |
|----------------------------|---------------------------|---------------------------------|-----|-----|-----|---------------------------------|-----|-----|-----|
| | | EL3 | EL2 | EL1 | EL0 | EL3 | EL2 | EL1 | EL0 |
| Four | Both | Yes | Yes | Yes | Yes | Yes | Yes | Yes | Yes |
| | | Yes | Yes | Yes | Yes | No | No | Yes | Yes |
| | | Yes | Yes | Yes | Yes | No | No | No | Yes |
| | | Yes | Yes | Yes | Yes | No | No | No | No |
| | | No | No | No | No | Yes | Yes | Yes | Yes |
| Three | Both | Yes | No | Yes | Yes | No | No | Yes | Yes |
| | | Yes | No | Yes | Yes | No | No | No | Yes |
| | | Yes | No | Yes | Yes | No | No | No | No |
| | | No | No | No | No | Yes | No | Yes | Yes |
| | Non-secure only | No | Yes | Yes | Yes | No | No | Yes | Yes |
| | | No | Yes | Yes | Yes | No | No | No | No |
| Two | Either | No | No | Yes | Yes | No | No | No | Yes |
| | | No | No | Yes | Yes | No | No | No | No |
| | | No | No | No | No | No | No | Yes | Yes |

D1.21.3 Implementations not including Advanced SIMD and floating-point instructions

In general, ARMv8-A requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementations targeting specialized markets that do not require support for floating-point or use of Advanced SIMD, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation:

In AArch64 state

- The `CPACR_EL1.FPEN` field is RES0.
- The `CPTR_EL2.TFP` bit is RES1.
- The `CPTR_EL3.TFP` bit is RES1.
- Each of the `ID_AA64PFR0_EL1`.{AdvSIMD, FP} fields is 0b1111.
- The `FPEXC32_EL2`, `FPCR`, and `FPSR` registers are not implemented, and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
 - All Advanced SIMD and floating-point instructions are UNDEFINED.
 - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.
- If at least one Exception level supports execution in AArch32 state, the `MVFR0_EL1`, `MVFR1_EL1` and `MVFR2_EL1` registers are RAZ. When no Exception level supports execution in AArch32 state these registers are UNKNOWN.

In AArch32 state

See [AArch32 implications of not including support for Advanced SIMD and floating-point on page G1-3880](#).

D1.21.4 The effects of supporting fewer than four Exception levels

[The effect of implementation choices on the programmers' model on page D1-1619](#) defines the permitted combinations of Exception levels in an ARMv8-A implementation.

In every implementation that supports the highest Exception level using either AArch64 state or AArch32 state, an IMPLEMENTATION DEFINED mechanism determines whether the highest implemented Exception level uses AArch64 state or AArch32 state from a Cold reset. Typically, this mechanism is a configuration input. When the highest level is configured to be AArch64 state, then after a Cold reset execution starts at the reset vector in that Exception level.

The unimplemented Exception levels have no effect on execution:

- No interrupts are routed to these Exception levels.
- No traps that target these Exception levels are active
- All systems calls to unimplemented Exception levels from lower Exception levels are treated as UNDEFINED.
- There is no support for address translation from these Exception levels.
- Any exception return that targets an unimplemented Exception level is treated as an illegal exception return as described in [Illegal return events from AArch64 state on page D1-1537](#).
- Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

————— Note —————

If, for example, EL3 is not implemented and EL2 is the highest implemented Exception level, then because none of the EL3 registers are accessible from EL2, the content of those registers is not architecturally visible.

The following subsections give more information about each of the permitted combinations of Exception levels that do not include all Exception levels.

Behavior when EL2 is not implemented

If EL2 is not implemented and EL3 is implemented:

- If EL1 can use AArch32 then the following registers are not RES0:
 - [DACR32_EL2](#).
 - [IFSR32_EL2](#).
 - [FPEXC32_EL2](#).
 - [DBGVCR32_EL2](#).
 - The [VMPIDR_EL2](#) and [VPIDR_EL2](#) behave as follows:
 - Reads of [VMPIDR_EL2](#) return the value of [MPIDR_EL1](#), writes to [VMPIDR_EL2](#) are ignored.
 - Reads of [VPIDR_EL2](#) return the value of [MIDR_EL1](#), writes to [VPIDR_EL2](#) are ignored.
 - Behavior is consistent with the [HCR_EL2.RW](#) bit taking the value of the [SCR_EL3.RW](#) bit for all purposes other than reading the [HCR_EL2](#).
 - Virtual interrupts are disabled.
 - The following address translation and TLB invalidation instructions are UNDEFINED:
 - [AT S1E2R](#) and [AT S1E2W](#).
 - [TLBI VAE2](#), [TLBI VALE2](#), [TLBI VAE2IS](#), [TLBI VALE2IS](#), [TLBI ALLE2](#), [TLBI ALLE2IS](#).
- Note**
- No other TLB or address translation instructions become UNDEFINED with this combination of Exception levels.
- The [SCR_EL3.HCE](#) bit is RES0.

If EL2 is not implemented, regardless of whether EL3 is implemented:

- The [CNTHCTL_EL2](#)[1:0] bits are treated as if they have the value 0b11 for all purposes other than reading the [CNTHCTL_EL2](#) register.
- The [MDCR_EL2.HPMN](#) bit taking the value of the [PMCR_EL0.N](#) bit for all purposes other than reading the value of [MDCR_EL2.HPMN](#)

Behavior when EL3 is not implemented and EL2 is implemented

If EL3 is not implemented and EL2 is implemented, then:

- All memory transactions can only access a single physical memory address space.
- The PE behaves as if the value of the [SCR_EL3.NS](#) bit is 1, even though the [SCR_EL3](#) is not accessible.

This means that if the PE is part of a system that supports two Security states, it behaves as if it is in Non-secure state, and can only access Non-secure memory.

Behavior when only EL1 and EL0 are implemented

If EL3 and EL2 are not implemented, it is IMPLEMENTATION DEFINED whether the PE behaves as if the value of the [SCR_EL3.NS](#) bit is 1 or the PE behaves as if the value of the [SCR_EL3.NS](#) bit is 0.

This means that if the PE is part of a system that supports two Security states:

- If it behaves as if the value of the [SCR_EL3.NS](#) bit is 1, it can only access Non-secure memory.
- If it behaves as if the value of the [SCR_EL3.NS](#) bit is 0, it can access both Secure memory and Non-secure memory.

If the PE behaves as if the value of the [SCR_EL3.NS](#) bit is 0, then:

- The [MDCR_EL3](#).{EPMAD, EDAD, SPME} bits behave as if they have the value 1.

- The [MDCR_EL3.SPD32](#) field behaves as if it has the value 0b11.

———— **Note** —————

- The behavior described in this subsection still applies if EL1 is configured to use AArch32.
- The implementation can provide a configuration input that determines, from reset, whether the it behaves as if the value of the [SCR_EL3.NS](#) bit is 1, or as if the value of the [SCR_EL3.NS](#) bit is 0.

—————

Chapter D2

AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug exception model. It is organized as follows:

Introductory information

- [About self-hosted debug](#) on page D2-1626.
- [The debug exception enable controls](#) on page D2-1630.

The debug Exception model

- [Routing debug exceptions](#) on page D2-1631.
- [Enabling debug exceptions from the current Exception level and Security state](#) on page D2-1633.
- [The effect of powerdown on debug exceptions](#) on page D2-1635.
- [Summary of the routing and enabling of debug exceptions](#) on page D2-1636.
- [Pseudocode description of debug exceptions](#) on page D2-1638.

The debug exceptions

- [Breakpoint Instruction exceptions](#) on page D2-1639.
- [Breakpoint exceptions](#) on page D2-1641.
- [Watchpoint exceptions](#) on page D2-1657.
- [Vector Catch exceptions](#) on page D2-1672.
- [Software Step exceptions](#) on page D2-1673.

Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a [Context synchronization event](#) guarantees the effects of the changes:

- [Synchronization and debug exceptions](#) on page D2-1687.

D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, that are taken using the exception model described in [Chapter D1 The AArch64 System Level Programmers' Model](#). This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- [Definition of a debugger in the context of self-hosted debug](#).
- [Context ID and Process ID](#).
- [About debug exceptions](#).

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A `CONTEXTIDR_ELx` identifies the current *Context ID*, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the `CONTEXTIDR_ELx` has a single field, `PROCID`, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in an AArch64 stage 1 translation regime are:

- [Breakpoint Instruction exceptions on page D2-1627](#).
- [Breakpoint exceptions on page D2-1627](#), generated by hardware breakpoints.
- [Watchpoint exceptions on page D2-1627](#), generated by hardware watchpoints.
- [Software Step exceptions on page D2-1628](#).

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See [Routing debug exceptions on page D2-1631](#). [Chapter G2](#) describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that are never generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. [Vector Catch exceptions on page D2-1672](#) describes the behavior for this case.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.
See [Enabling debug exceptions from the current Exception level and Security state on page D2-1633](#). Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
2. A debugger has enabled that particular debug exception.
All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the `MDSCR_EL1`. See [The debug exception enable controls on page D2-1630](#).

Note

If *halting is allowed* and `EDSCR.HDE` is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see [Halting allowed and halting prohibited on page H2-4845](#).

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

PE behavior

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see [Breakpoint Instruction exceptions on page D2-1639](#).

Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- Address.
 - Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
 - Context ID Match. Matches with the Context ID held in the `CONTEXTIDR_EL1`.
 - VMID Match. Matches with the VMID value held in the `VTTBR_EL2`.
 - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see [Breakpoint exceptions on page D2-1641](#).

Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range 0x1000 - 0x101F.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see [Watchpoint exceptions on page D2-1657](#).

Vector Catch exceptions

These are not generated in an AArch64 translation regime. They can only be generated in an AArch32 translation regime. See [Vector Catch exceptions on page D2-1672](#).

Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

PE behavior

Software step can only be used by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see [Software Step exceptions on page D2-1673](#).

[Table D2-1](#) summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table D2-1 PE behavior and pseudocode for each of the debug exceptions

| Debug exception | PE behavior if debug exceptions are: | | Pseudocode |
|-----------------------------------|--------------------------------------|-----------------------------|------------------------------|
| | Enabled | Disabled | |
| Breakpoint Instruction exceptions | Takes the exception | Takes the exception | page D2-1640 |
| Breakpoint exceptions | Takes the exception ^a | Ignored | page D2-1655 |
| Watchpoint exceptions | Takes the exception ^a | Ignored | page D2-1670 |
| Vector Catch exceptions | Takes the exception | Ignored | page G2-3981 |
| Software Step exceptions | Takes the exception | Not applicable ^b | page D2-1686 |

a. If halting is allowed and `EDSCR.HDE` is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See [Chapter H2 Debug State](#).

- b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.

D2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

[MDSR_EL1.MDE](#), plus an enable control for each breakpoint, [DBGBCR<n>_EL1.E](#).

Watchpoint exceptions

[MDSR_EL1.MDE](#), plus an enable control for each watchpoint, [DBGWCR<n>_EL1.E](#).

Vector Catch exceptions

[MDSR_EL1.MDE](#).

Software Step exceptions

[MDSR_EL1.SS](#).

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1633](#).

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

D2.3 Routing debug exceptions

Debug exceptions are usually routed to EL1. However:

- If EL2 is implemented, the routing of debug exceptions taken from Non-secure state depends on [MDCR_EL2.TDE](#):
 - 1** Debug exceptions taken from Non-secure state are routed to EL2.
 - 0** Debug exceptions behave as follows:
 - Debug exceptions taken from Non-secure EL1 and EL0 are routed to Non-secure EL1.
 - Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
 - All other debug exceptions are disabled from EL2 using AArch64.

———— **Note** —————

If [HCR_EL2.TGE](#) is 1, [MDCR_EL2.TDE](#) is treated as being 1 except for a direct read of [MDCR_EL2](#).

[Table D2-2](#) shows this.

Table D2-2 The effect of the TGE and TDE controls on debug exception routing

| HCR_EL2.TGE | MDCR_EL2.TDE | Debug exceptions taken from Non-secure state are routed to: |
|-----------------------------|------------------------------|---|
| 0 | 0 | Non-secure EL1 ^a |
| 0 | 1 | EL2 |
| 1 | X | EL2 |

a. Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

———— **Note** —————

If EL2 is not implemented, the PE behaves as if both [HCR_EL2.TGE](#) and [MDCR_EL2.TDE](#) are 0.

- If EL3 is implemented, Breakpoint Instruction exceptions taken from EL3 are routed to EL3. All other debug exceptions are disabled from EL3 using AArch64.

Either EL1 or EL2 is the *debug target exception level*, EL_D . That is, EL_D is EL1 unless EL2 is implemented and [MDCR_EL2.TDE](#) is 1 and the debug exception is taken from Non-secure state, when EL_D is EL2.

The following tables show the routing of debug exceptions:

Table D2-3 Routing when both EL3 and EL2 are implemented

| MDCR_EL2.TDE ^a | EL_D when executing in: | | | | | |
|---|---------------------------|-----|------------------|---------|-----|------------------|
| | Non-secure: | | | Secure: | | |
| | EL0 | EL1 | EL2 | EL0 | EL1 | EL3 |
| 0 | EL1 | EL1 | EL1 ^b | EL1 | EL1 | EL1 ^b |
| 1 | EL2 | EL2 | EL2 | | | |

a. If [HCR_EL2.TGE](#) is 1, this bit is treated as being 1 other than for a direct read of [MDCR_EL2](#).

b. EL_D is EL1. However, all debug exceptions other than Breakpoint Instruction exceptions are disabled, and Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

Table D2-4 Routing when EL3 is implemented and EL2 is not implemented

| EL _D when executing in: | | | |
|------------------------------------|-----|---------|------------------|
| Non-secure: | | Secure: | |
| EL0 | EL1 | EL1 | EL3 |
| EL1 | EL1 | EL1 | EL1 ^a |

- a. EL_D is EL1. However, all debug exceptions other than Breakpoint Instruction exceptions are disabled, and Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

Table D2-5 Routing when EL3 is not implemented and EL2 is implemented

| MDCR_EL2.TDE ^a | EL _D when executing in Non-secure: | | |
|---------------------------|---|-----|------------------|
| | EL0 | EL1 | EL2 |
| 0 | EL1 | EL1 | EL1 ^b |
| 1 | EL2 | EL2 | EL2 |

- a. If HCR_EL2.TGE is 1, this bit is treated as being 1 other than for a direct read of MDCR_EL2.
b. EL_D is EL1. However, all debug exceptions other than Breakpoint Instruction exceptions are disabled, and Breakpoint Instruction exceptions taken from EL2 are routed to EL2.

D2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level.

`DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

These functions are described in [Chapter J1 ARMv8 Pseudocode](#).

D2.4 Enabling debug exceptions from the current Exception level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus() == FALSE`.
- The debug exception is enabled from the current Exception level.
- The debug exception is enabled from the current Security state.

Table D2-6 shows when debug exceptions are enabled from the current Exception level. In the table, EL_D is the Exception level that Table D2-3 on page D2-1631 defines.

Table D2-6 Whether debug exceptions are enabled from the current Exception level

| Current Exception level | Breakpoint Instruction exceptions | All other debug exceptions |
|--|-----------------------------------|---|
| Any Exception level that is higher than EL_D^a | Enabled | Disabled |
| EL_D | Enabled | Disabled if either of the following is true: <ul style="list-style-type: none"> • The Local (kernel) Debug Enable bit, <code>MDCR_EL1.KDE</code>, is 0. • The Debug exception mask bit, <code>PSTATE.D</code>, is 1. Otherwise enabled. This means that a debugger must explicitly enable these debug exceptions from EL_D by setting <code>MDCR_EL1.KDE</code> to 1 and <code>PSTATE.D</code> to 0. |
| Any Exception level that is lower than EL_D | Enabled | Enabled |

a. This includes EL_3 . EL_3 is always higher than EL_D .

———— **Note** ————

`PSTATE.D` is set to 1 at reset and on exception entry.

Table D2-7 shows when debug exceptions are enabled from the current Security state.

Table D2-7 Whether debug exceptions are enabled from the current Security state

| Current Security state | Breakpoint Instruction exceptions | All other debug exceptions |
|------------------------|-----------------------------------|--|
| Non-secure | Enabled | Enabled |
| Secure | Enabled | Disabled if <code>MDCR_EL3.SDD</code> is 1. See <i>Disabling debug exceptions from Secure state</i> on page D2-1634. Otherwise enabled. |

D2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can set the *Secure Debug Disable* bit, `MDCR_EL3.SDD`, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

———— **Note** —————

- If the boot software executed when reset is deasserted sets `MDCR_EL3.SDD` to 1, software operating at EL3 never has to switch the debug registers between Secure state and Non-secure state.
- The PE cannot take a debug exception unless it is enabled from the current Exception level. See [Table D2-6 on page D2-1633](#).
- If either the OS lock or the OS double-lock is locked, debug exceptions other than Breakpoint Instruction exceptions are disabled.
- If EL3 and EL2 are not implemented, and the implementation is a Secure state only implementation, the PE behaves as if `MDCR_EL3.SDD` is 0.

D2.4.2 Pseudocode description of enabling debug exceptions

`AArch64.GenerateDebugExceptions()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

`AArch64.GenerateDebugExceptionsFrom()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in [Chapter J1 ARMv8 Pseudocode](#).

D2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-4951 describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `DoubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

D2.6 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. [Table D2-8](#) shows the routing of these. In the table, n/a means not applicable.

Table D2-8 Routing of Breakpoint Instruction exceptions

| Current Security state | MDCR_EL2.TDE ^a | EL _D when enabled from: | | | |
|------------------------|---------------------------|------------------------------------|----------------|-----|-----|
| | | EL0 | EL1 | EL2 | EL3 |
| Secure | X | Secure EL1 | Secure EL1 | n/a | EL3 |
| Non-secure | 0 | Non-secure EL1 | Non-secure EL1 | EL2 | n/a |
| | 1 | EL2 | EL2 | EL2 | n/a |

a. If EL2 is not implemented, behavior is as if this is 0. Otherwise, if the value of [HCR_EL2.TGE](#) is 1, [MDCR_EL2.TDE](#) is treated as being 1 other than for a direct read of [MDCR_EL2](#).

All other debug exceptions

[Table D2-9](#) shows the valid combinations of [MDCR_EL3.SDD](#), [MDCR_EL2.TDE](#), [MDSR_EL1.KDE](#), and [PSTATE.D](#), and for each combination shows where these exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table D2-9 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

| Debug state | Lock ^a | Current Security state | SDD ^b | TDE ^c | KDE | D | EL _D when enabled from: | | | |
|-------------|-------------------|------------------------|------------------|------------------|-----|---|------------------------------------|----------------|-----|-----|
| | | | | | | | EL0 | EL1 | EL2 | EL3 |
| Yes | X | X | X | X | X | X | - | - | - | - |
| No | TRUE | X | X | X | X | X | - | - | - | - |
| No | FALSE | Secure | 1 | X | X | X | - | - | n/a | - |
| No | FALSE | Secure | 0 | X | 0 | X | Secure EL1 | - | n/a | - |
| No | FALSE | Secure | 0 | X | 1 | 1 | Secure EL1 | - | n/a | - |
| No | FALSE | Secure | 0 | X | 1 | 0 | Secure EL1 | Secure EL1 | n/a | - |
| No | FALSE | Non-secure | X | 0 | 0 | X | Non-secure EL1 | - | - | n/a |
| No | FALSE | Non-secure | X | 0 | 1 | 1 | Non-secure EL1 | - | - | n/a |
| No | FALSE | Non-secure | X | 0 | 1 | 0 | Non-secure EL1 | Non-secure EL1 | - | n/a |
| No | FALSE | Non-secure | X | 1 | 0 | X | EL2 | EL2 | - | n/a |
| No | FALSE | Non-secure | X | 1 | 1 | 1 | EL2 | EL2 | - | n/a |
| No | FALSE | Non-secure | X | 1 | 1 | 0 | EL2 | EL2 | EL2 | n/a |

a. The value of [\(OSLSR_EL1.OSLK == '1' || DoubleLockStatus\(\)\)](#).

b. If EL3 is not implemented, behavior is as if this is 0.

- c. If [HCR_EL2.TGE](#) is 1, this bit is treated as being 1 other than for a direct read of [MDCR_EL2](#). If EL2 is not implemented, behavior is as if TDE is 0.

D2.7 Pseudocode description of debug exceptions

[AArch64.DebugFault\(\)](#) returns a `FaultRecord` object that indicates that a memory access has generated a debug exception:

The [AArch64.Abort\(\)](#) function processes `FaultRecord` objects, as described in *Abort exceptions* on page D3-1719, and generates a debug exception.

[AArch64.Abort\(\)](#) calls one of the following:

- [AArch64.BreakpointException\(\)](#).
- [AArch64.WatchpointException\(\)](#).
- [AArch64.VectorCatchException\(\)](#).
- [AArch64.SoftwareStepException\(\)](#).

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

D2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 BRK instruction. However, within the AArch64 EL1&0 translation regime, executing a T32 or A32 BKPT instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 BKPT instructions see:

- [Breakpoint instruction in the A32 and T32 instruction sets on page G2-3935](#).
- [BKPT instructions as the first instruction in an IT block on page G2-3936](#).

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

- [About Breakpoint Instruction exceptions](#).
- [Breakpoint instructions](#).
- [Exception syndrome information and preferred return address on page D2-1640](#).
- [Pseudocode description of Breakpoint Instruction exceptions on page D2-1640](#).

D2.8.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. [Breakpoint exceptions on page D2-1641](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D , is using AArch64 or AArch32.

Note

- The debug target exception level, EL_D , is the Exception level that debug exceptions are targeting. [Routing debug exceptions on page D2-1631](#) describes how EL_D is derived.
 - Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions on page B2-83](#).
-

D2.8.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is BRK #<immediate>. It is unconditional.

For details of the instruction encoding, see [BRK on page C6-475](#).

The breakpoint instruction in the A32 and T32 instruction sets is BKPT #<immediate>.

For more information about the A32 and T32 breakpoint instruction, see [Breakpoint instruction in the A32 and T32 instruction sets on page G2-3935](#).

D2.8.3 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address](#).

Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR_EL1](#).
- [ESR_EL2](#).
- [ESR_EL3](#).

———— **Note** —————

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

[Table D2-10](#) shows the information that the PE records.

Table D2-10 Information recorded in the [ESR_ELx](#)

| ESR_ELx field | Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3. | |
|--|--|--|
| <i>Exception Class</i> , EC | Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to: <ul style="list-style-type: none"> • 0x3C for an A64 BRK instruction. • 0x38 for an A32 or T32 BKPT instruction. | |
| <i>Instruction Length</i> , IL | The PE sets this to: <ul style="list-style-type: none"> • 0 for a 16-bit T32 BKPT instruction. • 1 for an A64 BRK instruction, or an A32 BKPT instruction. | |
| <i>Instruction Specific Syndrome</i> , ISS | ISS[24:16] | RES0. |
| | ISS[15:0] | The PE copies the instruction Comment field value into here, zero extended as necessary. |

———— **Note** —————

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, [ESR_EL2.EC](#) is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see [Routing debug exceptions on page D2-1631](#).

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like SVC.

D2.8.4 Pseudocode description of Breakpoint Instruction exceptions

[AArch64.SoftwareBreakpoint\(\)](#) generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in [Chapter J1 ARMv8 Pseudocode](#).

D2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Breakpoint exceptions.](#)
- [Breakpoint types and linking of breakpoints on page D2-1642.](#)
- [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1648.](#)
- [Breakpoint instruction address comparisons on page D2-1650.](#)
- [Breakpoint context comparisons on page D2-1651.](#)
- [Breakpoint usage constraints on page D2-1651.](#)
- [Exception syndrome information and preferred return address on page D2-1655.](#)
- [Pseudocode description of Breakpoint exceptions taken from AArch64 state on page D2-1655.](#)

D2.9.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions on page D2-1639](#).

An implementation can include between 2-16 hardware breakpoints. [ID_AA64DFR0_EL1.BRPs](#) shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>_EL1](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>_EL1](#). This holds the value used for breakpoint matching, that is one of:
 - An instruction virtual address.
 - A Context ID.
 - A VMID value.
 - A concatenation of both a Context ID value and a VMID value.

These registers are numbered, so that:

- [DBGBCR1_EL1](#) and [DBGBVR1_EL1](#) are for breakpoint number one.
- [DBGBCR2_EL1](#) and [DBGBVR2_EL1](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n>_EL1](#) and [DBGBVR<n>_EL1](#) are for breakpoint number n.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, `DBGBCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGBCR<n>_EL1` are met.
- The comparison with the value held in the `DBGBVR<n>_EL1` is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its condition code check.
- The instruction type.

If halting is allowed and `EDSCR.HDE` is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

———— **Note** —————

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page D2-1630 describes the enable controls for Breakpoint debug events.

D2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
 - An instruction address match.
 - A Context ID match, with the value held in the `CONTEXTIDR_EL1`.
 - A VMID match, with the VMID value held in the `VTTBR_EL2`.
 - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match.

`ID_AA64DFR0_EL1.CTX_CMPs` shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>_EL1.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

Figure D2-1 shows all of the possible breakpoint types that stage 1 of an AArch64 translation regime supports, and their associated BT field values.

| | | Unlinked | Linked |
|---------------------|---------------------------|--|--|
| Address breakpoints | Address Match | BT == 0b0000 Unlinked Address Match | BT == 0b0001 Linked Address Match |
| Context breakpoints | Context ID Match | BT == 0b0010 Unlinked Context ID Match | BT == 0b0011 Linked Context ID Match |
| | VMID Match | BT == 0b1000 Unlinked VMID Match | BT == 0b1001 Linked VMID Match |
| | VMID and context ID Match | BT == 0b1010 Unlinked VMID and Context ID Match | BT == 0b1011 Linked VMID and Context ID Match |

Figure D2-1 Breakpoint types and their associated BT field values

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on on page D2-1650](#).

Note

Stage 1 of an AArch32 translation regimes supports two additional breakpoint types, Unlinked and Linked Address Mismatch breakpoints, `BT == 0b0100` and `BT == 0b0101`. For information about these, see [Chapter G2 AArch32 Self-hosted Debug](#). These types are reserved in stage 1 of an AArch64 translation regime. See [Reserved BT values on page D2-1652](#).

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>_EL1.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1648](#).
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See [Other usage constraints for Address breakpoints on page D2-1654](#).
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

———— **Note** —————

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. [Watchpoint exceptions on page D2-1657](#) describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

[Figure D2-2 on page D2-1645](#) shows an example of permitted breakpoint and watchpoint linking.

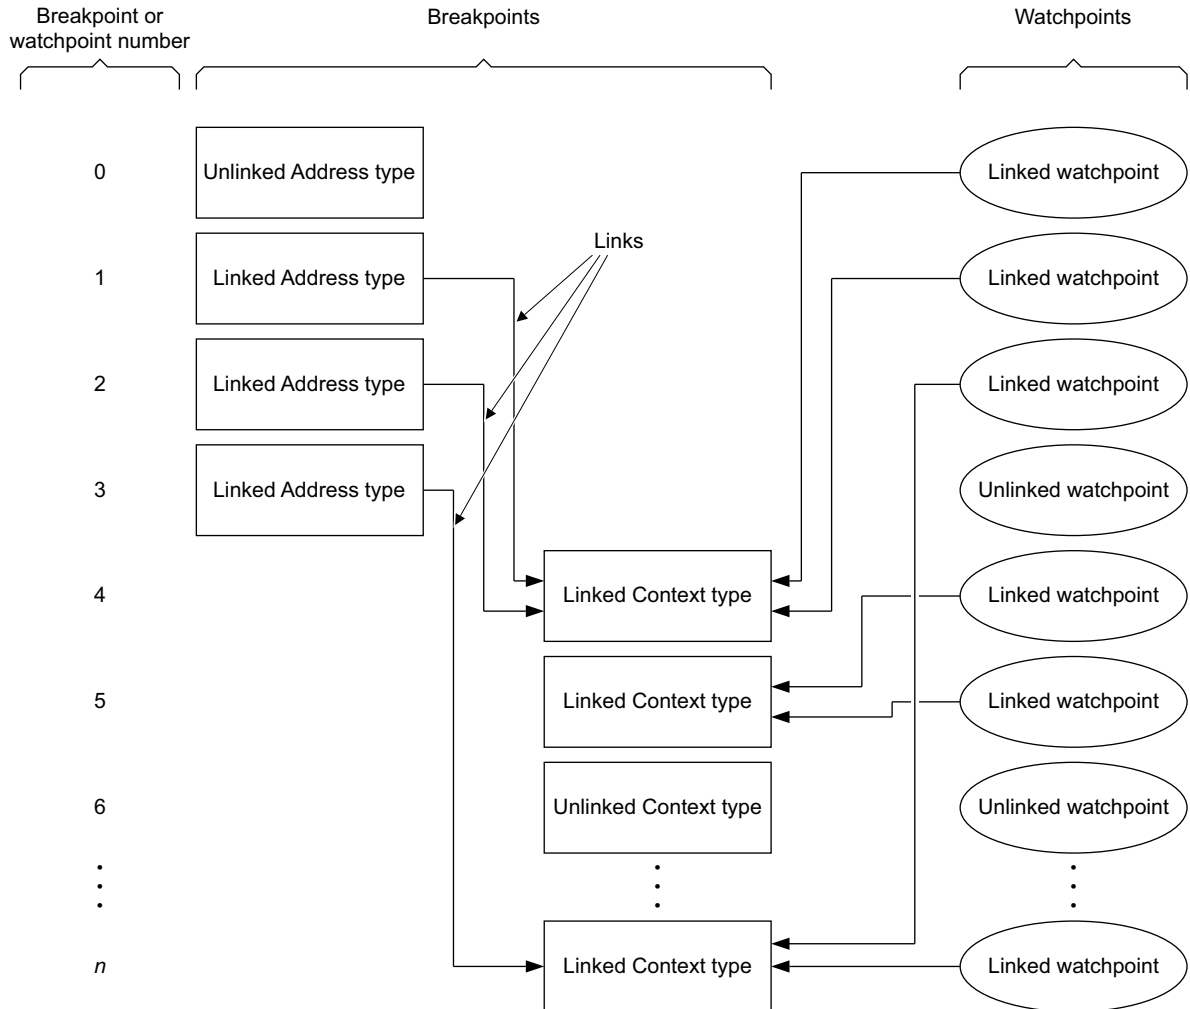

Figure D2-2 The role of linking in Breakpoint and Watchpoint exception generation

In [Figure D2-2](#), each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links, to are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

Breakpoint types defined by DBGBCR_n_EL1.BT

The following list provides more detail about each breakpoint type:

0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>_EL1.{SSC, HMC, PMC}](#). These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#) on page D2-1648.
- A successful address match, as described in [Breakpoint instruction address comparisons](#) on page D2-1650.

[DBGBCR<n>_EL1.LBN](#) for this breakpoint is ignored.

0b0001, Linked Address Match breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>_EL1**.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#) on page D2-1648.
- A successful address match defined by this breakpoint, as described in [Breakpoint instruction address comparisons](#) on page D2-1650.
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, Unlinked Context ID Match breakpoint

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1**.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See [Execution conditions for which a breakpoint generates Breakpoint exceptions](#) on page D2-1648.
- A successful Context ID match, as described in [Breakpoint context comparisons](#) on page D2-1651.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored

0b0011, Linked Context ID Match breakpoint

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons](#) on page D2-1650.
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#) on page D2-1651.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons](#) on page D2-1662.
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons](#) on page D2-1651.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, Unlinked Address Mismatch breakpoint

BT == 0b0100 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values](#) on page D2-1652.

[0b0100, Unlinked Address Mismatch breakpoint](#) on page G2-3943 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b0101, Linked Address Mismatch breakpoint

BT == 0b0101 is a reserved value in stage 1 of an AArch64 translation regime. See [Reserved BT values](#) on page D2-1652.

[0b0101, Linked Address Mismatch breakpoint](#) on page G2-3944 describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>_EL1**.{SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1648*.
- A successful VMID match, as described in *Breakpoint context comparisons on page D2-1651*.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See *Breakpoint instruction address comparisons on page D2-1650*.
 - A successful VMID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-1651*.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons on page D2-1662*.
 - A successful VMID match defined by this breakpoint, as described in *Breakpoint context comparisons on page D2-1651*.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>_EL1**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions on page D2-1648*.
- A successful Context ID match, as described in *Breakpoint context comparisons on page D2-1651*.
- A successful VMID match.

Breakpoint context comparisons on page D2-1651 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any Breakpoint exceptions.
- Generation of a Breakpoint exception depends on all of the following:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page D2-1650](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1651](#).
 - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page D2-1662](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page D2-1651](#).
 - A successful VMID match defined by this breakpoint.

[Breakpoint context comparisons on page D2-1651](#) describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

Note

See [Reserved DBGBCR<n>_EL1.BT values on page D2-1652](#) for the behavior of breakpoints programmed with reserved BT values.

D2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<n>_EL1.{SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

Note

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

[Table D2-11 on page D2-1649](#) shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

Y or - Means that a breakpoint programmed with the values of HMC, SSC, and PMC shown in that row:
Y Can generate Breakpoint exceptions in that Exception level.
- Cannot generate Breakpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PMC is reserved. See *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-1652*.

Table D2-11 Summary of breakpoint HMC, SSC, and PMC encodings

| HMC | SSC | PMC | Security state the breakpoint is programmed to match in | EL3 ^a | EL2 | EL1 | EL0 | Implementation | |
|-----|-----|-----|---|------------------|-----|-----|-----|----------------|----------------------------|
| | | | | | | | | No EL3 | No EL3 and no EL2 |
| 0 | 00 | 01 | Both | - | - | Y | - | - | - |
| 0 | 00 | 10 | | - | - | - | Y | - | - |
| 0 | 00 | 11 | | - | - | Y | Y | - | - |
| 0 | 01 | 01 | Non-secure | - | - | Y | - | Res | Res |
| 0 | 01 | 10 | | - | - | - | Y | Res | Res |
| 0 | 01 | 11 | | - | - | Y | Y | Res | Res |
| 0 | 10 | 01 | Secure | - | - | Y | - | Res | Res |
| 0 | 10 | 10 | | - | - | - | Y | Res | Res |
| 0 | 10 | 11 | | - | - | Y | Y | Res | Res |
| 1 | 00 | 01 | Both | Y | Y | Y | - | - | Res |
| 1 | 00 | 11 | | Y | Y | Y | Y | - | Res |
| 1 | 01 | 01 | Non-secure | - | Y | Y | - | Res | Res |
| 1 | 01 | 11 | | - | Y | Y | Y | Res | Res |
| 1 | 10 | 00 | Secure | Y | - | - | - | Res | Res |
| 1 | 10 | 01 | | Y | - | Y | - | Res | Res |
| 1 | 10 | 11 | | Y | - | Y | Y | Res | Res |
| 1 | 11 | 00 | Non-secure | - | Y | - | - | - | Res if no EL2 ^b |

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See *Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-1652*.

D2.9.4 Breakpoint instruction address comparisons

An address comparison is successful if bits [48:2] of the current instruction virtual address are equal to `DBGBVR<n>_EL1`[48:2].

———— **Note** —————

`DBGBVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits. `DBGBVR<n>_EL1`[1:0] are RES0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, A32 and T32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the *Byte Address Selection* field, `DBGBCR<n>_EL1.BAS`.

Table D2-12 Programmable BAS values

| BAS | Match instruction at | Constraint for debuggers |
|--------|--------------------------------------|-----------------------------------|
| 0b0011 | <code>DBGBCR<n>_EL1</code> | Use for T32 instructions. |
| 0b1100 | <code>DBGBCR<n>_EL1 + 2</code> | Use for T32 instructions. |
| 0b1111 | <code>DBGBCR<n>_EL1</code> | Use for A64 and A32 instructions. |

If the implementation is an AArch64-only implementation, all instructions are word-aligned and `DBGBCR<n>_EL1.BAS` is RES1.

Figure D2-3 on page D2-1651 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with `DBGBCR<n>_EL1.BAS` programmed as either 0b0011 or 0b1111 generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

———— **Note** —————

To breakpoint on an A64 instruction, ARM recommends that the debugger programs `DBGBCR<n>_EL1.BAS` as 0b1111.

In the figure:

- Yes** Means that the breakpoint generates a Breakpoint exception.
- No** Means that the breakpoint does not generate a Breakpoint exception.
- UNP** Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints* on page D2-1654.

| | Instruction set | Size | Location of instruction ^a | | | | | | | | BAS[3:0] | | | |
|-------|-----------------|--------|--------------------------------------|----|---|----|----|----|----|----|----------|--------|--------|-----|
| | | | -2 | -1 | 0 | +1 | +2 | +3 | +4 | +5 | 0b0011 | 0b1100 | 0b1111 | |
| Row 1 | T32 | 16-bit | | | ■ | | | | | | | Yes | No | Yes |
| Row 2 | | 16-bit | | | | | ■ | | | | | No | Yes | UNP |
| Row 3 | T32 | 32-bit | ■ | ■ | ■ | | | | | | | UNP | No | UNP |
| Row 4 | | 32-bit | | | ■ | ■ | ■ | | | | | Yes | UNP | Yes |
| Row 5 | | 32-bit | | | | | ■ | ■ | ■ | | | No | Yes | UNP |
| Row 6 | A32 | 32-bit | ■ | ■ | ■ | ■ | | | | | | Yes | UNP | Yes |
| Row 7 | A64 | 32-bit | ■ | ■ | ■ | ■ | | | | | | Yes | UNP | Yes |

- a. 0 means the word-aligned address held in the `DBGVCR<n>_EL1[48:2]:00`. The other locations are as follows:
- 2 means $((\text{DBGVCR}\langle n \rangle_EL1[48:2]:00) - 2)$.
 - 1 means $((\text{DBGVCR}\langle n \rangle_EL1[48:2]:00) - 1)$.
 - ...
 - ...
 - +5 means $((\text{DBGVCR}\langle n \rangle_EL1[48:2]:00) + 5)$.

The solid areas show the location of the instruction.

Figure D2-3 Summary of BAS field meanings for Address Match breakpoints

D2.9.5 Breakpoint context comparisons

The breakpoint type defined by `DBGVCR<n>_EL1.BT` determines what context comparison is required, if any. [Table D2-13](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-13 Breakpoint context comparison tests

| <code>DBGVCR<n>.BT</code> | Test required for successful context comparison |
|---------------------------------|--|
| 0b001x | <code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR<n>_EL1.ContextID</code> value |
| 0b100x | <code>VTTBR_EL2.VMID</code> value matches <code>DBGVCR<n>_EL1.VMID</code> value |
| 0b101x | <code>CONTEXTIDR_EL1</code> value matches <code>DBGVCR<n>_EL1.ContextID</code> value and <code>VTTBR_EL2.VMID</code> value matches <code>DBGVCR<n>_EL1.VMID</code> value |

No context comparison is required for other valid `DBGVCR<n>.BT` values.

Context breakpoints do not generate Breakpoint exceptions when execution is in EL2 using either Execution state, or when execution is in EL3 using AArch64.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

Note

- For all Context breakpoints, `DBGVCR<n>_EL1.BAS` is RES1 and is ignored.
- For Linked Context breakpoints, `DBGVCR<n>_EL1.{LBN, SSC, HMC, PMC}` are RES0 and are ignored.

D2.9.6 Breakpoint usage constraints

See the following sections:

- [Reserved `DBGVCR<n>_EL1.BT` values on page D2-1652.](#)
- [Reserved `DBGVCR<n>_EL1.{SSC, HMC, PMC}` values on page D2-1652.](#)

- [Reserved DBGBCR<n>_EL1.BAS values](#) on page D2-1653.
- [Reserved DBGBCR<n>_EL1.LBN values](#) on page D2-1654.
- [Other usage constraints for Address breakpoints](#) on page D2-1654.
- [Other usage constraints for Context breakpoints](#) on page D2-1654.

Reserved DBGBCR<n>_EL1.BT values

Table D2-14 shows when particular DBGBCR<n>_EL1.BT values are reserved.

Table D2-14 Reserved BT values

| BT value | Breakpoint type | Reserved |
|----------|---------------------------|--|
| 0b001x | Context ID Match | For non context-aware breakpoints |
| 0b010x | Address Mismatch | In stage 1 of an AArch64 translation regime, or if EDSCR.HDE is 1 and halting is allowed |
| 0b011x | - | Always |
| 0b100x | VMID Match | For non context-aware breakpoints, or if EL2 is not implemented |
| 0b101x | Context ID and VMID Match | |
| 0b11xx | - | Always |

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.
- For a direct or external read of DBGBCR<n>_EL1, if the reserved BT value:
 - Has no function for any execution conditions, the value read back is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values

Table D2-15 shows when particular combinations of DBGBCR<n>_EL1.{SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

Table D2-15 Reserved HMC, SSC, and PMC combinations

| HMC, SSC, and PMC combination | Reserved |
|--|---|
| All combinations with SSC set to 0b01 or 0b10. | When EL3 is not implemented and EL2 is implemented. |

Table D2-15 Reserved HMC, SSC, and PMC combinations (continued)

| HMC, SSC, and PMC combination | Reserved |
|--|--|
| Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When both of EL2 and EL3 are not implemented |
| The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When EL2 is not implemented |
| Combinations not included in Table D2-11 on page D2-1649 . | Always |

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
 - The breakpoint must behave as if it is disabled.
 - A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
 - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
 - A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of `DBGBCR<n>_EL1.{SSC, HMC, PMC}` returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved `DBGBCR<n>_EL1.BAS` values

In an AArch64-only implementation, `DBGBCR<n>_EL1.BAS` for all breakpoints is RES1.

Otherwise:

For all Context breakpoints

`DBGBCR<n>_EL1.BAS` is RES1 and is ignored.

For all Address breakpoints

[Table D2-12 on page D2-1650](#) gives the valid values of the `DBGBCR<n>_EL1.BAS` field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BAS value that is not reserved, other than for a direct or external read of `DBGBCR<n>_EL1`.
- A direct or external read of `DBGBCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGBCR<n>_EL1.LBN values

For all Context breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGBCR<n>_EL1.LBN return an UNKNOWN value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

DBGBCR<n>_EL1.LBN reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
 - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
 - If DBGBCR<n>.BAS is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For Linked Context breakpoints

If no Linked Address breakpoints or Linked watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

D2.9.7 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address](#).

Exception syndrome information

On taking a Breakpoint exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR_EL1](#).
- [ESR_EL2](#).

———— Note —————

Breakpoint exceptions cannot be taken to EL3 using AArch64.

[Table D2-16](#) shows the information that the PE records.

Table D2-16 Information recorded in the [ESR_ELx](#)

| ESR_ELx field | Information recorded in ESR_EL1 or ESR_EL2 . | |
|--|--|--|
| <i>Exception Class</i> , EC | The PE sets this to: <ul style="list-style-type: none"> • 0x30, if the exception was taken from a lower Exception level. • 0x31, if the exception was taken without a change of Exception level. | |
| <i>Instruction Length</i> , IL | The PE sets this to 1. | |
| <i>Instruction Specific Syndrome</i> , ISS | ISS[24:6] | RES0. |
| | ISS[5:0] | <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010. |

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch64 state

[AArch64.BreakpointValueMatch\(\)](#) tests the value in [DBGBVR<n>_EL1](#).

[AArch64.StateMatch\(\)](#) tests the values in [DBGBCR<n>_EL1](#).{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

For a watchpoint, [AArch64.StateMatch\(\)](#) tests the values in [DBGWCR<n>_EL1](#).{SSC, HMC, PAC} and, if the watchpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

[AArch64.BreakpointMatch\(\)](#) tests a committed instruction against all breakpoints.

[AArch64.CheckBreakpoint\(\)](#) generates a Breakpoint exception if all of the following are true:

- [MDSCR_EL1.MDE](#) is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1633](#).
- All of the conditions required for Breakpoint exception generation are met. See [About Breakpoint exceptions on page D2-1641](#).

———— **Note** —————

[AArch64.CheckBreakpoint\(\)](#) might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.BreakpointException\(\)](#) is called to generate a Breakpoint exception.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

D2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing either:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.

This section contains the following subsections:

- [About Watchpoint exceptions.](#)
- [Watchpoint types and linking of watchpoints on page D2-1659.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1660.](#)
- [Watchpoint data address comparisons on page D2-1662.](#)
- [Determining the memory location that caused a Watchpoint exception on page D2-1665.](#)
- [Watchpoint behavior on other instructions on page D2-1666.](#)
- [Watchpoint usage constraints on page D2-1667.](#)
- [Exception syndrome information and preferred return address on page D2-1669.](#)
- [Pseudocode description of Watchpoint exceptions taken from AArch64 state on page D2-1670.](#)

D2.10.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, `ID_AA64DFR0_EL1.WRPs` shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, `DBGWCR<n>_EL1`. This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, `DBGWVR<n>_EL1`. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- `DBGWCR1_EL1` and `DBGWVR1_EL1` are for watchpoint number one.
- `DBGWCR2_EL2` and `DBGWVR2_EL1` are for watchpoint number two.
- ...
- ...
- `DBGWCR<n>_EL1` and `DBGWVR<n>_EL1` are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>_EL1.BAS`, to select the bytes. See [Programming a watchpoint with eight bytes or fewer on page D2-1663](#).
- Eight bytes to 2GB, provided that both of the following are true:
 - The number of bytes is a power-of-two.
 - The range starts at an address that is aligned to the range size.A debugger uses the *MASK* field, `DBGWCR<n>_EL1.MASK`, to program a watchpoint with eight bytes to 2GB. See [Programming a watchpoint with eight or more bytes on page D2-1664](#).

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint debug events is `CONSTRAINED UNPREDICTABLE`. See [Programming dependencies of the *BAS* and *MASK* fields on page D2-1668](#).

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, `DBGWCR<n>_EL1.E`, is 1.
- The conditions specified in the `DBGWCR<n>_EL1` are met.
- The comparison with the address held in the `DBGWVR<n>_EL1` is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint also are successful. See [Figure D2-2 on page D2-1645](#). See also [Breakpoint context comparisons on page D2-1651](#).
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its condition code check.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

———— **Note** —————

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

[The debug exception enable controls on page D2-1630](#) describes the enable controls for Watchpoint debug events.

D2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, `DBGWCR<n>_EL1.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>_EL1.WT` is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGWCR<n>_EL1.LBN`, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
 - `DBGWCR<n>_EL1.WT.{SSC, HMC, PAC}` for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1660](#).
 - `DBGBCR<n>_EL1.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See [Watchpoint usage constraints on page D2-1667](#).
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions on page D2-1641](#) describes breakpoints.

Figure D2-2 on page D2-1645 shows an example of permitted watchpoint linking.

D2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2 in Non-secure state.

`DBGWCR<n>_EL1`, {SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

———— **Note** —————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level at which the access was made.

———— **Note** —————

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at EL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 Load unprivileged and Store unprivileged instructions are LDTR and STTR.

Table D2-17 on page D2-1661 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

Y or - Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
Y Can generate Watchpoint exceptions in that Exception level.
- Cannot generate Watchpoint exceptions in that Exception level.

Res Means that the combination of HMC, SSC, and PAC is reserved. See *Reserved DBGWCR<n>_EL1*, {SSC, HMC, PAC} values on page D2-1667.

Table D2-17 Summary of watchpoint HMC, SSC, and PAC encodings

| HMC | SSC | PAC | Security state the watchpoint is programmed to match in | EL3 ^a | EL2 | EL1 | EL0 | Implementation | |
|-----|-----|-----|---|------------------|-----|-----|-----|----------------|----------------------------|
| | | | | | | | | No EL3 | No EL3 and no EL2 |
| 0 | 00 | 01 | Both | - | - | Y | - | - | - |
| 0 | 00 | 10 | | - | - | - | Y | - | - |
| 0 | 00 | 11 | | - | - | Y | Y | - | - |
| 0 | 01 | 01 | Non-secure | - | - | Y | - | Res | Res |
| 0 | 01 | 10 | | - | - | - | Y | Res | Res |
| 0 | 01 | 11 | | - | - | Y | Y | Res | Res |
| 0 | 10 | 01 | Secure | - | - | Y | - | Res | Res |
| 0 | 10 | 10 | | - | - | - | Y | Res | Res |
| 0 | 10 | 11 | | - | - | Y | Y | Res | Res |
| 1 | 00 | 01 | Both | Y | Y | Y | - | - | Res |
| 1 | 00 | 11 | | Y | Y | Y | Y | - | Res |
| 1 | 01 | 01 | Non-secure | - | Y | Y | - | Res | Res |
| 1 | 01 | 11 | | - | Y | Y | Y | Res | Res |
| 1 | 10 | 00 | Secure | Y | - | - | - | Res | Res |
| 1 | 10 | 01 | | Y | - | Y | - | Res | Res |
| 1 | 10 | 11 | | Y | - | Y | Y | Res | Res |
| 1 | 11 | 00 | Non-secure | - | Y | - | - | - | Res if no EL2 ^b |

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at EL3 using AArch64.

b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See [Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values on page D2-1667](#).

D2.10.4 Watchpoint data address comparisons

An address comparison is successful if bits [48:2] of the current data virtual address are equal to `DBGWVR<n>_EL1[48:2]`, taking into account all of the following:

- The size of the access. See *Size of the data access*.
If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, data addresses are zero-extended before comparison with the watchpoint.
- The bytes selected by `DBGWVR<n>_EL1.BAS`. See *Programming a watchpoint with eight bytes or fewer* on page D2-1663.
- Any address ranges indicated by `DBGWVR<n>_EL1.MASK`. See *Programming a watchpoint with eight or more bytes* on page D2-1664.

Note

- `DBGWVR<n>_EL1` is a 64-bit register. The most significant bits of this register are sign-extension bits.
 - `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored
-

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. See [Example D2-1](#).

Example D2-1

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by DC ZVA instructions is the DC ZVA block size that `DCZID_EL0.BS` defines.

The size of data accesses initiated by DC IVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
 - The size that `CTR_EL0.DminLine` defines.
 - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, *Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction* on page D2-1666.

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, `DBGWCR<n>_EL1.BAS`, selects which bytes in the doubleword starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint generates Watchpoint exceptions for.

If the address programmed into the `DBGWVR<n>_EL1` is:

- Doubleword-aligned:
 - All eight bits of `DBGWCR<n>_EL1.BAS` are used, and the descriptions given in [Table D2-18](#) apply.
- Word-aligned but not doubleword-aligned:
 - Only `DBGWCR<n>_EL1.BAS[3:0]` are used, and the descriptions given in [Table D2-19](#) apply. In this case, `DBGWCR<n>_EL1.BAS[7:4]` are RES0.

Table D2-18 Supported BAS values when the `DBGWVRn_EL1` address alignment is doubleword

| BAS value | Description |
|-------------|---|
| 0b00000000 | Watchpoint never generates a Watchpoint exception. |
| BAS[0] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:000</code> is accessed. |
| BAS[1] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:001</code> is accessed. |
| BAS[2] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:010</code> is accessed. |
| BAS[3] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:011</code> is accessed. |
| BAS[4] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:100</code> is accessed. |
| BAS[5] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:101</code> is accessed. |
| BAS[6] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:110</code> is accessed. |
| BAS[7] == 1 | Generates a Watchpoint exception if the byte at address <code>DBGWVR<n>_EL1[48:3]:111</code> is accessed. |

Table D2-19 Supported BAS values when the `DBGWVRn_EL1` address alignment is word

| BAS value ^a | Description |
|------------------------|--|
| 0b00000000 | Watchpoint never generates a Watchpoint exception |
| BAS[0] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[48:2]:00</code> is accessed. |
| BAS[1] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[48:2]:01</code> is accessed. |
| BAS[2] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[48:2]:10</code> is accessed. |
| BAS[3] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>_EL1[48:2]:11</code> is accessed. |

a. `DBGWCR<n>_EL1.BAS[7:4]` are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see [Other usage constraints on page D2-1669](#).

When programming the BAS field with anything other than 0b11111111, a debugger must program `DBGWCR<n>_EL1.MASK` to be 0b000000. See [Programming dependencies of the BAS and MASK fields on page D2-1668](#).

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the `DBGWVR<n>_EL1`[48:3]. See [Example D2-1 on page D2-1662](#).

The following are some example configurations of the `BAS` field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address `0x1003`, program:
 - `DBGWVR<n>_EL1` with `0x1000`.
 - `DBGWCR<n>_EL1.BAS` to be `0b00001000`.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses `0x2003`, `0x2004` and `0x2005`, program:
 - `DBGWVR<n>_EL1` with `0x2000`.
 - `DBGWCR<n>_EL1.BAS` to be `0b00111000`.
- If the address programmed into the `DBGWVR<n>_EL1` is doubleword-aligned:
 - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program `DBGWCR<n>_EL1.BAS` to be `0b00001111`.
 - To generate a Watchpoint exception when any byte in the word starting at address `DBGWVR<n>_EL1`[31:3]:100 is accessed, program `DBGWCR<n>_EL1.BAS` to be `0b11110000`.

———— **Note** —————

ARM deprecates programming a `DBGWVR<n>_EL1` with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the `MASK` field, `DBGWCR<n>_EL1.MASK`, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
 - A power-of-two.
 - A minimum of eight bytes.
 - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The `MASK` field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

| | | |
|-------------|----------------------|--|
| MASK | <code>0b00000</code> | No bits are masked. |
| | <code>0b00001</code> | Reserved. |
| | <code>0b00010</code> | Reserved. |
| | <code>0b00011</code> | Three least significant bits are masked. |
| | <code>0b00100</code> | Four least significant bits are masked. |
| | <code>0b00101</code> | Five least significant bits are masked. |
| | ... | ... |
| | <code>0b11111</code> | 31 least significant bits are masked. |

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address `DBGWVR<n>_EL1[48:n]:000...`
- Address `DBGWVR<n>_EL1[48:n]:111...`
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between `DBGWVR<n>_EL1[48:4]:0000` and `DBGWVR<n>_EL1[48:4]:1111`, including these addresses.

———— Note ————

- The 17 most significant bits cannot be masked. This means that the full address cannot be masked.
- For watchpoint behavior when its MASK field is programmed with a reserved value, see [Reserved DBGWCR<n>_EL1.MASK values on page D2-1668](#).

When masking address bits, a debugger must both:

- Program `DBGWCR<n>_EL1.BAS` to be `0b11111111`. See [Programming dependencies of the BAS and MASK fields on page D2-1668](#).
- In the `DBGWVR<n>_EL1`, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints on page D2-1669](#).

D2.10.5 Determining the memory location that caused a Watchpoint exception

On taking a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- `FAR_EL1`, if the exception is taken to EL1.
- `FAR_EL2`, if the exception is taken to EL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the `EDWAR`.

For more information, see the subsections that follow. These are:

- [Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions](#)
- [Address recorded for Watchpoint exceptions generated by Data Cache instructions on page D2-1666](#)

Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
 - The lowest address accessed by the memory access that triggered the watchpoint.
 - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
 - A power-of-two size.
 - No larger than the DC ZVA block size.
 - Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example D2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
 - 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.
-

Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

D2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except DC IVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

———— Note —————

The DC ZVA instruction is not a data cache maintenance instruction.

See also the following subsections:

- [Watchpoint behavior on accesses by Store-Exclusive instructions.](#)
- [Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction.](#)

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an exclusive monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA instruction

DC IVAC and DC ZVA operations are treated as data stores. This means that for a watchpoint to match on an access caused by one of these instructions, the debugger must program `DBGWCR<n>_EL1.LSC` to be one of the following:

- 10** Match on data stores.

- 11 Match on data stores and data loads.

Note

For the size of data accesses performed by the DC IVAC instruction and the DC ZVA instruction, see [Watchpoint data address comparisons on page D2-1662](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.10.7 Watchpoint usage constraints

See the following:

- [Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values.](#)
- [Reserved DBGWCR<n>_EL1.LBN values.](#)
- [Programming dependencies of the BAS and MASK fields on page D2-1668.](#)
- [Reserved DBGWCR<n>_EL1.BAS values on page D2-1668.](#)
- [Reserved DBGWCR<n>_EL1.MASK values on page D2-1668.](#)
- [Other usage constraints on page D2-1669.](#)

Reserved DBGWCR<n>_EL1.{SSC, HMC, PAC} values

Table D2-20 shows when particular combinations of DBGWCR<n>_EL1.{SSC, HMC, PAC} are reserved.

Table D2-20 Reserved SSC, HMC, and PAC combinations

| HMC, SSC, and PMC combination | Reserved |
|---|---|
| All combinations with SSC set to 0b01 or 0b10. | When EL3 is not implemented and EL2 is implemented. |
| All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When both of EL2 and EL3 are not implemented |
| The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When EL2 is not implemented |
| Combinations not included in Table D2-17 on page D2-1661 . | Always |

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>_EL1.
- For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
 - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>_EL1.LBN values

For Linked Watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>_EL1.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGWCR<n>_EL1.LBN` return an UNKNOWN value and the behavior is CONstrained UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Watchpoints For Unlinked watchpoints, `DBGWCR<n>_EL1.LBN` reads UNKNOWN and its value is ignored.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the `DBGWVR<n>_EL1` the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be `0b000000`, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to `0b11111111`, then for each byte in the address range, it is CONstrained UNPREDICTABLE whether or not a Watchpoint exception is generated.

Reserved `DBGWCR<n>_EL1.BAS` values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- `n` is a non-zero positive integer less-than-or-equal-to 8.
- `m` is a positive integer less-than 8.
- `n+m` is less-than-or-equal-to 8.

All other values are reserved.

———— **Note** —————

If `x` is zero, then `Zeros(x)` is an empty bitstring.

If `DBGWVR<n>_EL1[2]` is 1, `DBGWCR<n>_EL1.BAS[7:4]` are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONstrained UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the `DBGWVR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved `DBGWCR<n>_EL1.MASK` values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
 - Disabled.

- Programmed with an UNKNOWN value that is not reserved, that might be 0b00000, other than for a direct or external read of `DBGWCR<n>_EL1`.
- A direct or external read of `DBGWCR<n>_EL1.MASK` returns an UNKNOWN value.

Other usage constraints

For all watchpoints:

- `DBGWVR<n>_EL1[1:0]` are RES0 and are ignored.
- If `DBGWCR<n>_EL1.MASK` is nonzero, and any masked bits of `DBGWVR<n>_EL1` are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if `DBGWCR<n>_EL1.LSC` is 0b00.

D2.10.8 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page D2-1670](#).

Exception syndrome information

On taking a Watchpoint exception, the PE records all of the following:

- Information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to.
- An address that the debugger can use to determine the memory location that caused the exception. The PE records this in a *Fault Address Register* (FAR).

The ESR and FAR used is either:

- `ESR_EL1` and `FAR_EL1`, if the exception is taken to EL1.
- `ESR_EL2` and `FAR_EL2`, if the exception is taken to EL2.

———— **Note** —————

Watchpoint exceptions cannot be taken to EL3 using AArch64.

Table D2-21 shows the recorded information.

Table D2-21 Information recorded in the ESR_ELx

| ESR_ELx field | Information recorded in ESR_EL1 or ESR_EL2 | |
|------------------------------------|---|--|
| Exception Class, EC | This is set to: <ul style="list-style-type: none"> 0x34, if the exception was taken from a lower Exception level. 0x35, if the exception was taken without a change of Exception level. | |
| Instruction Length, IL | This is set to 1. | |
| Instruction Specific Syndrome, ISS | ISS[24] | Instruction Syndrome Valid (ISV). This is 0, because Watchpoint exceptions are not stage 2 aborts. |
| | ISS[23:9] | RES0. |
| | ISS[8] | Cache Maintenance (CM). This indicates whether a cache maintenance instruction generated the exception: <ul style="list-style-type: none"> 0 Not generated by a cache maintenance instruction. 1 Generated by a cache maintenance instruction. If a DC ZVA instruction generated the exception, CM is 0. |
| | ISS[7] | RES0. |
| | ISS[6] | Write-not-Read (WnR). This indicates whether the access was by a read instruction or a write instruction: <ul style="list-style-type: none"> 0 Read instruction. 1 Write instruction. |
| | ISS[5:0] | Data Fault Status Code (DFSC). The PE sets this to the code for a debug exception, 0b100010. |

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

`AArch64.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch64.StateMatch()` tests the values in `DBGWCR<n>_EL1`.{HMC, SSC, PAC}, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch64.WatchpointMatch()` tests the value in `DBGWVR<n>_EL1`.

`AArch64.CheckWatchpoint()` generates a `FaultRecord` that `AArch64.Abort()` raises a Watchpoint exception for if all of the following are true:

- `MDSCR_EL1.MDE` is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1633.
- All of the conditions required for Watchpoint exception generation are met. See *About Watchpoint exceptions* on page D2-1657.

———— **Note** ————

`AArch64.CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

[AArch64.WatchpointException\(\)](#) is called to generate a Watchpoint exception.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

D2.11 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

———— **Note** ————

This means that they are never taken to EL1 using AArch64 and are only supported if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See [Routing debug exceptions on page D2-1631](#).

`AArch64.VectorCatchException()` is called to generate a Vector Catch exception.

[Vector Catch exceptions on page G2-3975](#) describes Vector Catch exceptions.

D2.12 Software Step exceptions

The following subsections describe Software Step exceptions:

- [About Software Step exceptions.](#)
- [Rules for setting MDSCR_EL1.SS to 1.](#)
- [The software step state machine on page D2-1674.](#)
- [Entering the active-not-pending state on page D2-1675.](#)
- [Behavior in the active-not-pending state on page D2-1679.](#)
- [Entering the active-pending state on page D2-1681.](#)
- [Behavior in the active-pending state on page D2-1681.](#)
- [Stepping T32 IT instructions on page D2-1682.](#)
- [Exception syndrome information and preferred return address on page D2-1682.](#)
- [Additional considerations on page D2-1684.](#)
- [Pseudocode description of Software Step exceptions on page D2-1686.](#)

D2.12.1 About Software Step exceptions

Software step is an ARMv8-A resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
 - a. Enables software step by setting [MDSCR_EL1.SS](#) to 1. See [The debug exception enable controls on page D2-1630.](#)
 - b. Executes an exception return instruction, ERET, to branch to the instruction to be single-stepped in the software being debugged.
2. The PE then:
 - a. Executes the instruction to be single-stepped.
 - b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated while the instruction is being stepped. This exception is either:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception that is taken before or after the instruction being stepped.

The PE can only take a Software Step exception if debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Exception level and Security state on page D2-1633.](#)

A state machine describes the behavior of software step, shown in [The software step state machine on page D2-1674.](#)

Throughout this [Software Step exceptions](#) section, including in all subsections, EL_D means the Exception level that Software Step exceptions are targeting. [Routing debug exceptions on page D2-1631](#) defines EL_D as the *debug target Exception level*.

D2.12.2 Rules for setting MDSCR_EL1.SS to 1

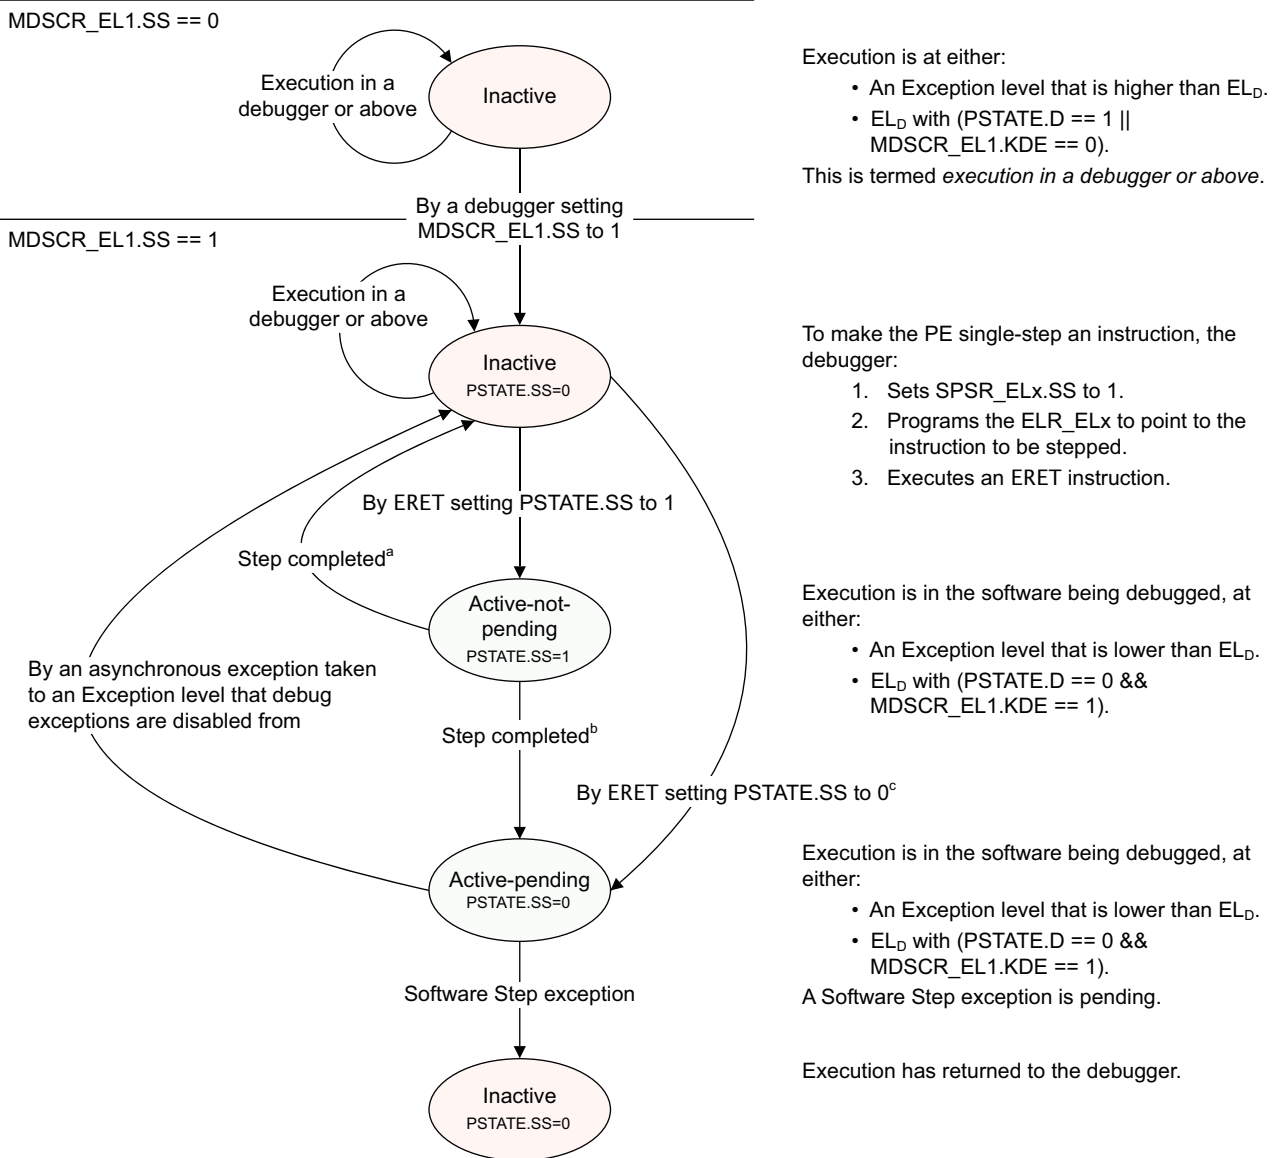

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets [MDSCR_EL1.SS](#) to 1.

The Exception level that hosts the debugger software must be using AArch64.

D2.12.3 The software step state machine

In Figure D2-4:

- The OS Lock is unlocked and `DoubleLockStatus() == FALSE`.
- The PE is not in Secure state with `MDCR_EL3.SDD` set to 1. That is, the PE is in Non-secure state, or is in Secure state with `MDCR_EL3.SDD` set to 0, or the implementation does not include EL3.

a. The step is the PE either:

- Taking an exception to an Exception level that debug exceptions are disabled from.
- If execution is at `ELD` with `MDCR_EL1.KDE == 1`, executing an instruction that sets `PSTATE.D` to 1.

Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from `ELD` when `PSTATE.D` is 1.

b. The step is the PE either:

- Executing the instruction to be stepped without taking an exception.
- Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at `ELD` with `MDCR_EL1.KDE == 1`, by software setting `PSTATE.D` to 0.

Figure D2-4 Software step state machine

For a description of when debug exceptions are enabled or disabled from an Exception level, see [Enabling debug exceptions from the current Exception level and Security state](#) on page D2-1633.

For more information about how a step is completed, see [Behavior in the active-not-pending state](#) on page D2-1679.

The software step states are:

- Inactive** Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:
- [MDCR_EL1.SS](#) is 0.
 - EL_D is using AArch32.
 - Debug exceptions are disabled from the current Exception level or Security state.

Active-not-pending

None of the conditions mentioned in [Inactive](#) are true, therefore software step is active.
The current instruction is the instruction to be stepped.

Active-pending

None of the conditions mentioned in [Inactive](#) are true, therefore software step is active.
A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not pending state or the active-pending state depends on [PSTATE.SS](#). [Table D2-22](#) shows this.

Table D2-22 State machine states

| EL_D using: | Debug exception enable status in the current Exception level and Security state | MDCR_EL1.SS | PSTATE.SS | State machine state |
|---------------|---|-----------------------------|---------------------------|---------------------|
| AArch32 | X | X | X | Inactive |
| AArch64 | Disabled | X | X | Inactive |
| AArch64 | Enabled | 0 | X | Inactive |
| AArch64 | Enabled | 1 | 1 | Active-not-pending |
| AArch64 | Enabled | 1 | 0 | Active-pending |

D2.12.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an ERET instruction writes 1 to [PSTATE.SS](#), by copying from [SPSR_ELx.SS](#) when it restores [PSTATE](#).
- Might enter the active-not-pending state on exiting Debug state when [DPSR_EL0.SS](#) or [DPSR.SS](#) is 1. See [Exiting Debug state](#) on page H2-4880.

An ERET instruction only copies 1 from [SPSR_ELx.SS](#) to [PSTATE.SS](#) if all of the following are true:

- [MDCR_EL1.SS](#) is 1.
- EL_D is using AArch64.
- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the ERET instruction targets.

Otherwise, ERET instructions set [PSTATE.SS](#) to 0, regardless of the value of [SPSR_ELx.SS](#).

Table D2-23 shows this. In the table:

- Lock** Means the value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- NS** Is SCR_EL3.NS.
- SDD** Is MDCR_EL3.SDD. See *Disabling debug exceptions from Secure state* on page D2-1634.
- TDE** Is MDCR_EL2.TDE. See *Routing debug exceptions on page D2-1631*.

Table D2-23 Value an ERET writes to PSTATE.SS

| MDSCR_EL1.SS | Lock | NS | SDD | TDE | EL1 is using | EL2 is using | Value an ERET writes to PSTATE.SS | |
|--------------|-------|----|-----|-----|--------------|--------------|-----------------------------------|---------------------------------|
| 0 | X | X | X | X | X | X | 0 | |
| 1 | TRUE | X | X | X | X | X | 0 | |
| | FALSE | 0 | 1 | X | X | n/a | 0 | |
| | | | | 0 | X | AArch32 | n/a | 0 |
| | | | | | | AArch64 | n/a | See Table D2-24 on page D2-1677 |
| | | | 1 | X | 0 | AArch32 | X | 0 |
| | | | | | | AArch64 | AArch64 | See Table D2-24 on page D2-1677 |
| | | | | 1 | AArch32 | AArch32 | 0 | |
| | | | | | X | AArch64 | See Table D2-25 on page D2-1678 | |

For:

- SCR_EL3.NS == 0 or MDCR_EL2.TDE == 0, and EL1 using AArch64, so that EL_D is EL1 using AArch64, Table D2-24 on page D2-1677 shows the value an ERET writes to PSTATE.SS.
- SCR_EL3.NS == 1 and MDCR_EL2.TDE == 1 and EL2 using AArch64, so that EL_D is EL2 using AArch64, Table D2-25 on page D2-1678 shows the value an ERET writes to PSTATE.SS.

In both tables:

From EL Means the Exception level at which the PE executes the ERET instruction.

Target EL Is the target Exception level of the ERET.

Note

If the ERET is an illegal exception return, the target Exception level of the ERET is the current Exception level. See *Illegal return events from AArch64 state* on page D1-1537.

KDE Is MDSCR_EL1.KDE. See *Enabling debug exceptions from the current Exception level and Security state* on page D2-1633.

Table D2-24 Value an ERET writes to **PSTATE.SS** if **EL_D** is **EL1** using **AArch64**

| From EL | Target EL | KDE | PSTATE.D | SPSR_ELx.D | Software step enable status at: | | Value an ERET writes to PSTATE.SS | |
|---------|-----------|-----|----------|------------|---------------------------------|-----------------|--|-----------------------------|
| | | | | | From EL | Target EL | | |
| EL3 | EL3 | X | X | X | Disabled | Disabled | 0 | |
| | EL2 | X | X | X | Disabled | Disabled | 0 | |
| | EL1 | 0 | X | X | Disabled | Disabled | 0 | |
| | | | 1 | X | 1 | Disabled | Disabled | 0 |
| | | | | | 0 | Disabled | Enabled | SPSR_EL3.SS |
| | EL0 | X | X | X | Disabled | Enabled | SPSR_EL3.SS | |
| EL2 | EL2 | X | X | X | Disabled | Disabled | 0 | |
| | EL1 | 0 | X | X | Disabled | Disabled | 0 | |
| | | | 1 | X | 1 | Disabled | Disabled | 0 |
| | | | | | 0 | Disabled | Enabled | SPSR_EL2.SS |
| | EL0 | X | X | X | Disabled | Enabled | SPSR_EL2.SS | |
| EL1 | EL1 | 0 | X | X | Disabled | Disabled | 0 | |
| | | 1 | 0 | X | Enabled ^a | .. ^b | 0 | |
| | | | 1 | 1 | Disabled | Disabled | 0 | |
| | | | | 0 | Disabled | Enabled | SPSR_EL1.SS | |
| | EL0 | 0 | X | X | Disabled | Enabled | SPSR_EL1.SS | |
| | | 1 | 0 | X | Enabled ^a | Enabled | 0 | |
| | | | 1 | X | Disabled | Enabled | SPSR_EL1.SS | |

a. Because [MDSCR_EL1.SS](#) == 1, it means that the ERET is itself being stepped.

b. Depends on [SPSR_EL1.D](#).

Table D2-25 Value an ERET writes to **PSTATE.SS** if **EL_D** is EL2 using AArch64

| From EL | Target EL | KDE | PSTATE.D | SPSR_ELx.D | Software step enable status at: | | Value an ERET writes to PSTATE.SS |
|---------|-----------|-----|----------|------------|---------------------------------|-----------|--|
| | | | | | From EL | Target EL | |
| EL3 | EL3 | X | X | X | Disabled | Disabled | 0 |
| | EL2 | 0 | X | X | Disabled | Disabled | 0 |
| | | 1 | X | 1 | Disabled | Disabled | 0 |
| | | 0 | | 0 | Disabled | Enabled | SPSR_EL3.SS |
| | EL1 | X | X | X | Disabled | Enabled | SPSR_EL3.SS |
| | EL0 | X | X | X | Disabled | Enabled | SPSR_EL3.SS |
| EL2 | EL2 | 0 | X | X | Disabled | Disabled | 0 |
| | | 1 | 0 | X | Enabled ^a | _b | 0 |
| | | | 1 | 1 | Disabled | Disabled | 0 |
| | | 0 | | 0 | Disabled | Enabled | SPSR_EL2.SS |
| | EL1 | 0 | X | X | Disabled | Enabled | SPSR_EL2.SS |
| | | 1 | 0 | X | Enabled ^a | Enabled | 0 |
| | | | 1 | X | Disabled | Enabled | SPSR_EL2.SS |
| | EL0 | 0 | X | X | Disabled | Enabled | SPSR_EL2.SS |
| | | 1 | 0 | X | Enabled ^a | Enabled | 0 |
| | | | 1 | X | Disabled | Enabled | SPSR_EL2.SS |
| EL1 | EL1 | X | X | X | Enabled ^a | Enabled | 0 |
| | EL0 | X | X | X | Enabled ^a | Enabled | 0 |

a. Because **MDSR_EL1.SS** == 1, it means that the ERET is itself being stepped.

b. Depends on **SPSR_EL2.D**.

———— **Note** —————

No AArch32 instruction can set **PSTATE.SS** to 1.

D2.12.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
 - Completes it without taking a synchronous exception.
 - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without executing any instructions.
- Enters Debug state because of a *Halting debug event*.

If the PE executes the instruction to be stepped without taking any exceptions, then either of the following occurs after the instruction has been executed:

- The instruction has disabled debug by setting `PSTATE.D` to 1 and software step advances to the inactive state.
- The PE sets `PSTATE.SS` to 0 and software step advances to the active-pending state. See *Behavior in the active-pending state* on page D2-1681.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- *If the PE takes an exception to an Exception level that is using AArch64.*
- *If the PE takes an exception to an Exception level that is using AArch32* on page D2-1680.

If the PE enters Debug state because of a Halting debug event, behavior is as described in *Entering Debug state and Software Step* on page H2-4854.

If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets `SPSR_ELx.SS` to 0 or 1, depending on the exception. See [Table D2-26](#).
- Sets `PSTATE.SS` to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:
 - Enabled** Software step enters the active-pending state.
 - Disabled** Software step enters the inactive state.
 In either case, on taking the exception, a step is complete.
- Sets `PSTATE.D` to 1.

Table D2-26 Categorization of exceptions, for setting `SPSR_ELx.SS` to 0 or 1

| Exception description | Exceptions | <code>SPSR_ELx.SS</code> |
|--|--|--------------------------|
| Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped. | Supervisor Call (SVC) exceptions. Hypervisor Call (HVC) exceptions. Secure Monitor Call (SMC) exceptions. | 0 |
| Exceptions whose preferred return address is the address of the instruction to be stepped. | All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped. | 1 |

———— Note —————

If an SMC instruction executed at Non-secure EL1 is trapped to EL2 because `HCR_EL2.TSC` is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so `SPSR_ELx.SS` is set to 1, not 0.

If the PE takes an exception to an Exception level that is using AArch32

This can only happen when all of the following is true:

- EL2 is implemented and is using AArch64, the PE is executing in Non-secure state, and `MDCR_EL2.TDE` is 1. Because `MDCR_EL2.TDE` is 1, `EL_D` is EL2.
- The exception is taken to Non-secure EL1 using AArch32.

As part of exception entry, the PE sets `PSTATE.SS` to 0. This causes software step to enter the active-pending state.

———— **Note** ————

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because `EL_D` is EL2, and debug exceptions are always enabled from Exception levels that are lower than `EL_D`.
- AArch32 SPSRs have no SS bit. Where an `SPSR_ELx` register architecturally maps to an AArch32 `SPSR_<mode>` register, `SPSR_ELx.SS` maps to `SPSR_<mode>[21]`.
`SPSR_<mode>[21]` is always RES0. The PE always sets `SPSR_<mode>[21]` to 0 on taking an exception to an Exception level that is using AArch32.

Summary of behavior in the active-not-pending state

Table D2-27 summarizes behavior in the active-not-pending state.

Table D2-27 Summary of behavior in the active-not-pending state

| Event | Value written to <code>PSTATE.SS</code> | Target Exception level is using: | Details ^a | Value written to <code>SPSR_ELx.SS</code> | Next state |
|--------------|---|----------------------------------|------------------------|---|---|
| No exception | 0 | n/a | Disables Software step | n/a | Inactive |
| | | | Otherwise | n/a | Active-pending |
| Exception | 0 | AArch64 | Supervisor Call (SVC) | 0 | Active-pending or inactive ^b |
| | | | Hypervisor Call (HVC) | | |
| | | Secure Monitor Call (SMC) | 1 | Active-pending | |
| Other | 0 ^c | | | | |
| | | AArch32 | All | | Active-pending |

- For the *No exception* rows, this column shows the effect of the event.
For the *Exception* rows, this column shows the exception taken.
- Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See [Figure D2-4 on page D2-1674](#).
- `SPSR_<mode>[21]` is RES0.

D2.12.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- [MDSCR_EL1.SS](#) is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

———— Note ————

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to Non-secure EL1 when [MDSCR_EL2.TDE](#) is 1. Otherwise, debug exceptions are masked by [PSTATE.D](#), therefore they would be disabled from the target Exception level of the exception.

While software step is in the inactive state

The PE either:

- Executing an ERET instruction when [SPSR_ELx.SS](#) is 0.
- If [MDSCR_EL1.KDE](#) is 1, executing an MSR DAIF or MSR DAIFCLR instruction that clears [PSTATE.D](#) to 0.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to [MDSCR_EL1.KDE](#) or [MDSCR_EL1.SS](#). These writes require explicit synchronization to guarantee their effect. See [Synchronization and the software step state machine on page D2-1685](#).
- On exiting Debug state when [DPSR_EL0.SS](#) or [DPSR.SS](#) is 0. See [Exiting Debug state on page H2-4880](#).

D2.12.7 Behavior in the active-pending state

In this state, a Software Step exception is pending, and the PE takes it on the current instruction.

Software Step exceptions have priority over all other exceptions except asynchronous exceptions taken to an Exception level or Security state that debug exceptions are disabled from.

This means that there are some asynchronous exceptions that Software Step exceptions have priority over.

———— Note ————

- This is the only case where a synchronous exception explicitly has a higher priority than asynchronous exceptions.
- For a description of when debug exceptions are enabled or disabled from an Exception level or Security state, see [Enabling debug exceptions from the current Exception level and Security state on page D2-1633](#).

In cases where both a Software Step exception is pending and an asynchronous exception taken to an Exception level or Security state that debug exceptions are disabled from is pending, the architecture does not define which exception is taken first.

D2.12.8 Stepping T32 IT instructions

The ARMv8-A architecture permits a combination of an IT instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, that can disable some uses of the IT instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:

- [SCTLR_EL1.ITD](#) if execution is at EL0 using AArch32 when EL1 is using AArch64.
- [SCTLR.ITD](#) if execution is at Non-secure EL0 or EL1 using AArch32.
- [HSCTLR.ITD](#) if execution is at Non-secure EL2 using AArch32.

D2.12.9 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page D2-1684](#).

Exception syndrome information

On taking a Software Step exception, the PE records information about the exception in the Exception Syndrome Register (ESR) at the Exception level the exception is taken to. The ESR used is one of:

- [ESR_EL1](#).
- [ESR_EL2](#).

———— **Note** —————

Software Step exceptions cannot be taken to EL3.

[Table D2-28 on page D2-1683](#) shows the information that the PE records.

Table D2-28 Information recorded in the `ESR_ELx`

| ESR_ELx field | Information recorded in <code>ESR_EL1</code> or <code>ESR_EL2</code> | |
|---|---|---|
| <i>Exception Class, EC</i> | The PE sets this to: <ul style="list-style-type: none"> • 0x32, if the exception was taken from a lower Exception level. • 0x33, if the exception was taken from the current Exception level. | |
| <i>Instruction Length, IL</i> | The PE sets this to 1. | |
| <i>Instruction Specific Syndrome, ISS</i> | ISS[24] | <i>Instruction Syndrome Valid (ISV)</i> . This indicates whether the EX bit, ISS[6], is valid. The PE sets this to: <ul style="list-style-type: none"> 0 Not valid. 1 Valid. |
| | ISS[23:7] | RES0. |
| | ISS[6] | <i>Exclusive operation (EX)</i> . The PE sets this to indicate whether the instruction stepped was a Load-Exclusive instruction: <ul style="list-style-type: none"> 0 The stepped instruction was not a Load-Exclusive instruction. 1 The stepped instruction was a Load-Exclusive instruction. A debugger can use this information when stepping code that uses exclusive monitors. See Stepping code that uses exclusive monitors on page D2-1685 |
| | ISS[5:0] | <i>Instruction Fault Status Code (IFSC)</i> . The PE sets this to the code for a debug exception, 0b100010. |

When an instruction has been stepped, the PE sets:

- The value of ISS.ISV to 1, to indicate that the EX bit is valid.
- The value of EX to indicate whether the instruction stepped was a Load-Exclusive instruction, using the ISS.EX values shown in [Table D2-28](#).

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, the PE sets both `ESR_ELx.{ISV, EX}` to 0.

———— **Note** —————

An implementation that always sets ISV to 0 and never sets EX is not compliant.

`ESR_ELx.ISV` is UNKNOWN if, in the active-not-pending state, either:

- The instruction stepped was an ERET or an ISB. In these cases, `ESR_ELx.EX` is set to 0.
- `MDCR_EL2.TDE` was set to 1 and either:
 - The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1. In this case, the instruction to be stepped never completed.
 - The PE took an asynchronous exception to Non-secure EL1 before it could execute the instruction to be stepped. In this case, the instruction to be stepped was never executed.

In both of these cases, `ESR_ELx.EX` is set to the correct value for the instruction.

Table D2-29 shows the permitted scenarios.

Table D2-29 Values that the PE can record in ESR_ELx.{ISV, EX}

| Description | ESR_ELx.ISV | ESR_ELx.EX |
|--|-------------|---|
| Syndrome data is not available because no instruction was stepped. | 0 | 0 |
| Syndrome data is available because an instruction was stepped. The instruction stepped was an instruction other than a Load-Exclusive instruction. | 1 | 0 |
| Syndrome data is available because an instruction was stepped. The instruction stepped was a Load-Exclusive instruction. | 1 | 1 |
| The instruction stepped was an ERET or an ISB. | UNKNOWN | 0 |
| The instruction to be stepped generated a synchronous exception that was taken to Non-secure EL1. | UNKNOWN | Set to the correct value for the instruction. |
| The PE took an asynchronous exception before it could execute the instruction to be stepped. | UNKNOWN | Set to the correct value for the instruction. |

ESR_ELx.EX is UNKNOWN if the stepped instruction was a conditional Load-Exclusive instruction that failed its condition code test.

———— **Note** —————

A Load-Exclusive instruction is any one of the following:

- In the A64 instruction set, any instruction that has a mnemonic starting with either LDX or LDAX.
- In the A32 and T32 instruction sets, any instruction that has a mnemonic starting with either LDREX or LDAEX.

Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.12.10 Additional considerations

This section contains the following:

- *Behavior when an ERET instruction is an illegal exception return.*
- *Behavior when the instruction stepped writes a misaligned PC value on page D2-1685.*
- *Stepping code that uses exclusive monitors on page D2-1685.*
- *Synchronization and the software step state machine on page D2-1685.*

Behavior when an ERET instruction is an illegal exception return

If the conditions for entering the active-not-pending state in *Entering the active-not-pending state on page D2-1675* are met, but the PE executes an ERET instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the ERET, software step can advance from the inactive state to one of the active states. Consider the following case:

1. **MDSCR_EL1.SS** is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and **MDSCR_EL2.TDE** is 0, **MDSCR_EL1.KDE** is 1, and **PSTATE.D** is 1.
PSTATE.D == 1 is the reason why software step is inactive, because **PSTATE.D == 1** means that debug exceptions are disabled from the current Exception level.
2. The PE executes an ERET instruction.

- The intended target of the ERET is EL2. This means that the ERET is an illegal exception return because the intended target is higher than the Exception level the ERET it is executed at. In this case, the ERET must target EL1 instead of EL2.
If `SPSR_EL1.D` is 0, then on the ERET `PSTATE.D` becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether `SPSR_ELx.SS` is 1 or 0:

- If `SPSR_ELx.SS` is 1, software step advances to the active-not-pending state.
In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If `SPSR_ELx.SS` is 0, software step advances to the active-pending state.
In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets `SPSR_ELx.IL` to 1.

———— **Note** —————

[Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) shows the relative priorities of synchronous exceptions.

Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A PC alignment fault exception is generated.

AArch32 The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

Stepping code that uses exclusive monitors

The ARMv8-A architecture provides no mechanism for preserving the state of the exclusive monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the exclusive monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all exclusive monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see [Exception syndrome information and preferred return address on page D2-1682](#).

Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
- A write to an external debug register that affects the routing of debug exceptions.

Because the software step state machine indirectly reads these registers, it is not guaranteed to observe any new values until after a *Context synchronization event* has occurred.

In the time between a write to one of these registers and the next *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a *Context synchronization event*, the state machine must use the state of the PE after the write.

Example D2-3

-
1. Software changes `MDSCR_EL1.SS` from 0 to 1 when debug exceptions are enabled.
 2. The PE executes some instructions.
 3. A *Context synchronization event* occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if `MDSCR_EL1.SS` is 0, or enters the active-pending state because `MDSCR_EL1.SS` is 1. If it is in the:

- Inactive state, then after the *Context synchronization event*, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the *Context synchronization event*.

Note

A direct write to a Special-purpose register does not require explicit synchronization.

D2.12.11 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting `PSTATE.SS` to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to `PSTATE.SS` on an exception return or an exit from Debug state. See *Entering the active-not-pending state* on page D2-1675.

These functions are defined in *Chapter J1 ARMv8 Pseudocode*.

D2.13 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context synchronization event* has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a *Context synchronization event* has occurred.

For any instructions executed between the time when the change is made and the time when the next *Context synchronization event* occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-4

-
1. Software changes `MDSCR_ELI.MDE` from 0 to 1.
 2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
 3. A *Context synchronization event* occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-5

-
1. Software unlocks the OS lock.
 2. The PE executes some instructions.
 3. A *Context synchronization event* occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

- Some register updates are self-synchronizing. Others require an explicit *Context synchronization event*. For more information, see both:
 - *Accessing PSTATE fields* on page D1-1514.
 - *Synchronization requirements for AArch64 System registers* on page D7-1889.
 - *Synchronization of changes to the external debug registers* on page H8-4964.
 - See *Context synchronization event* for the definition of this term.
-

Chapter D3

The AArch64 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page D3-1690.
- *Address space* on page D3-1691.
- *Mixed-endian support* on page D3-1692.
- *Cache support* on page D3-1693.
- *External aborts* on page D3-1714.
- *Memory barrier instructions* on page D3-1716.
- *Pseudocode description of general memory system instructions* on page D3-1717.

D3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page B2-71](#).

D3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA), described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

D3.1.2 Memory attributes

[Memory types and attributes on page B2-94](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table D3-1](#) shows the memory attributes that are visible at the system level.

Table D3-1 Memory attribute summary

| Memory type | Shareability | Cacheability |
|---------------------|--|---|
| Device ^a | Outer Shareable | Non-cacheable. |
| Normal | One of: <ul style="list-style-type: none">• Non-shareable.• Inner Shareable.• Outer Shareable. | One of ^b : <ul style="list-style-type: none">• Non-cacheable.• Write-Through Cacheable.• Write-Back Cacheable. |

a. Takes additional attributes, see [Device memory on page B2-98](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page D3-1695](#).

For more information on cacheability and shareability see [Shareable Normal memory on page B2-95](#), [Non-shareable Normal memory on page B2-96](#), and [Caches and memory hierarchy on page B2-70](#).

D3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [Address size configuration](#) on page D4-1731.

D3.2.1 Instruction address space overflow

When a PE performs a *Simple sequential execution* of instructions, it calculates:

$$(\text{address_of_current_instruction}) + (\text{size_of_executed_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an instruction overflows `0xFFFF_FFFF_FFFF_FFFF`, the program counter becomes UNKNOWN.

———— **Note** —————

Address tags are not propagated to the program counter, so the tag does not affect the address calculation.

Where an instruction accesses a sequential set of bytes that crosses the `0xFFFF_FFFF_FFFF_FFFF` boundary when tagged addresses are not used, or the `0xxxFF_FFFF_FFFF_FFFF` boundary when tagged addresses are used, then the virtual address accessed for the bytes above this boundary is UNKNOWN. When tagged addresses are used, the value of the tag associated with the address also becomes UNKNOWN.

D3.3 Mixed-endian support

A control bit, [SCTLR_EL1.E0E](#) is provided to allow the endianness of explicit data accesses made while executing at EL0 to be controlled independently of those made while executing at EL1. [Table D3-2](#) shows the endianness of explicit data accesses and translation table walks.

Table D3-2 Endianness support

| Exception level | Explicit data accesses | Stage 1 translation table walks | Stage 2 translation table walks |
|-----------------|-------------------------------|---------------------------------|---------------------------------|
| EL0 | SCTLR_EL1.E0E | SCTLR_EL1.EE | SCTLR_EL2.EE |
| EL1 | SCTLR_EL1.EE | SCTLR_EL1.EE | SCTLR_EL2.EE |
| EL2 | SCTLR_EL2.EE | SCTLR_EL2.EE | N/A |
| EL3 | SCTLR_EL3.EE | SCTLR_EL3.EE | N/A |

———— **Note** —————

[SCTLR_EL1.E0E](#) has no effect on the endianness of the [LDTR](#), [LDTRH](#), [LDTRSH](#), and [LDTRSW](#) instructions, or on the endianness of the [STTR](#) and [STTRH](#) instructions, when these are executed at EL1.

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
 - [SCTLR_ELx.EE](#) is RW and [SCTLR_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
 - [SCTLR_ELx](#) is RES0 and [SCTLR_EL1.E0E](#) is RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
 - [SCTLR_ELx](#) is RES1 and [SCTLR_EL1.E0E](#) is RW.
- All Exception levels support only little-endianness:
 - [SCTLR_ELx](#) is RES0 and [SCTLR_EL1.E0E](#) is RES0.
- All Exception levels support only big-endianness:
 - [SCTLR_ELx](#) is RES1 and [SCTLR_EL1.E0E](#) is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by [PSTATE.E](#). For exception returns to AArch32 state, [PSTATE.E](#) is copied from [SPSR_ELx.E](#). If the target Exception level supports only little-endian accesses, [SPSR_ELx.E](#) is RES0. If the target Exception level supports only big-endian accesses, [SPSR_ELx.E](#) is RES1. [PSTATE.E](#) is ignored in AArch64 state.

The [BigEndian\(\)](#) function determines whether the current Exception level and Execution state are using big-endian data. This function is defined in [Chapter J1 ARMv8 Pseudocode](#).

D3.4 Cache support

This section describes the ARMv8 cache identification and control mechanisms, and the cache maintenance instructions, in the following sections:

- [General behavior of the caches.](#)
- [Cache identification on page D3-1694.](#)
- [Cacheability, cache allocation hints, and cache transient hints on page D3-1695.](#)
- [Enabling and disabling the caching of memory accesses on page D3-1696.](#)
- [Behavior of caches at reset on page D3-1698](#)
- [Non-cacheable accesses and instruction caches on page D3-1698.](#)
- [About cache maintenance in ARMv8 on page D3-1699.](#)
- [Cache maintenance instructions on page D3-1703](#)
- [Data cache zero instruction on page D3-1711.](#)
- [Cache lockdown on page D3-1712.](#)
- [System level caches on page D3-1713.](#)
- [Branch prediction on page D3-1713.](#)

See also [Caches in a VMSAv8-64 implementation on page D4-1829.](#)

D3.4.1 General behavior of the caches

When a memory location has a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
 - A particular implementation.
 - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.
- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

Note

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page D3-1712.](#)

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.

- It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
 - The translation regime at the current Exception level.
 - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the `CTR_ELO` identifies the Cache Write-back Granule.
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer if it was previously visible to that observer.

———— **Note** —————

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the `SCTLR_EL1`.{I, C} controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

D3.4.2 Cache identification

The ARMv8 cache identification registers describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes the cache maintenance instructions that:

- Affect the entire cache, for example `IC IALLU`.
- Operate by address, for example `IC IVAU`.
- Operate by set/way, for example `DC ISW`.

The cache identification registers are:

- The Cache Type Register, `CTR_ELO`, that defines:
 - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
 - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
 - The cache indexing and tagging policy of the Level 1 instruction cache.

———— **Note** —————

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see [System level caches on page D3-1713](#).

- A single Cache Level ID Register, `CLIDR_EL1`, that defines:
 - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
 - The *Level of Coherence* (LoC) for the caches. See [Terms used in describing the maintenance instructions on page D3-1699](#) for the definition of LoC.

- The *Level of Unification Uniprocessor* (LoUU) for the caches. See *Terms used in describing the maintenance instructions* on page D3-1699 for the definition of LoUU.
- An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, `CSSELR_EL1`, that selects the cache level and cache type of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, `CCSIDR_EL1`, that defines:
 - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
 - The number of sets, associativity and line length of the cache. See *Terms used in describing the maintenance instructions* on page D3-1699 for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.
3. For each cache identified at stage 2:
 - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
 - An instruction cache.
 - A data or unified cache.
 - Read the Cache Size ID Register to find details of the cache.

D3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and can be defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in *Memory types and attributes* on page B2-94, the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see *Transient cacheability hint* on page D3-1696.

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be assigned:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

Note

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-64 translation table walks, the `TCR_ELx.{IRGNn, ORGNn}` fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a *relatively short period*.

The description of the AArch64 `MAIR_EL1`, `MAIR_EL2`, and `MAIR_EL3` registers, and the AArch32 `MAIRO`, `MAIR1`, `HMAIRO`, and `HMAIR1` registers, includes the assignment of the Transient hint in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

D3.4.4 Enabling and disabling the caching of memory accesses

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

Note

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

The Cacheability control fields and their effects are as follows:

For the EL1&0 translation regime

- When the value of `SCTLR_EL1.C` is 0:
 - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the EL1&0 stage 1 translation tables are Non-cacheable.
- When the value of `SCTLR_EL1.I` is 0:
 - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.CD` is 1:
 - All stage 2 translations for data accesses to Normal memory are Non-cacheable.

- All accesses to the EL1&0 stage 2 translation tables are Non-cacheable.
- When the value of `HCR_EL2.ID` is 1:
 - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of `HCR_EL2.DC` is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of `SCTLR_EL1.{I, C}`. This applies to translations for both data and instruction accesses.

Note

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-1799](#).
- The `SCTLR_EL1.{C, I}` and `HCR_EL2.DC` fields have no effect on the EL2 and EL3 translation regimes.
- The `HCR_EL2.{ID, CD}` fields affect only stage 2 of the Non-secure EL1&0 translation regime.
- In Non-secure state, when EL2 is using AArch64 and EL1 is using AArch32, the `HCR_EL2.{ID, CD, DC}` controls apply as described here, but the EL1 controls are `SCTLR.{C, I}`.

For the EL2 translation regime

- When the value of `SCTLR_EL2.C` is 0:
 - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
 - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of `SCTLR_EL2.I` is 0:
 - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

Note

The `SCTLR_EL2.{I, C}` fields have no effect on the EL1&0 and EL3 translation regimes.

For the EL3 translation regime

- When the value of `SCTLR_EL3.C` is 0:
 - All data accesses to Normal memory using the EL3 translation regime are Non-cacheable.
 - All accesses to the EL3 translation tables are Non-cacheable.
- When the value of `SCTLR_EL3.I` is 0:
 - All instruction accesses to Normal memory using the EL3 translation regime are Non-cacheable.

Note

The `SCTLR_EL3.{I, C}` fields have no effect on the EL1&0 and EL2 translation regimes.

In addition:

- For translation regimes other than the Non-secure EL1&0 translation regime, if the value of `SCTLR_ELx.M` is 0, indicating that stage 1 translations are disabled for that translation regime, then:
 - If the value of `SCTLR_ELx.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.

- If the value of `SCTLR_ELx.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.
- For the Non-secure EL1&0 translation regime, if the value of `SCTLR_EL1.M` is 0, indicating that stage 1 translations are disabled for that translation regime, and the value of `HCR_EL2.DC` is 0:
 - If the value of `SCTLR_EL1.I` is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
 - If the value of `SCTLR_EL1.I` is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through Cacheable, Outer Write-Through Cacheable.

The effect of `SCTLR_ELx.C`, `HCR_EL2.DC` and `HCR_EL2.CD` is reflected in the result of the address translation instructions in the PAR when these bits have an effect on the stages of translation being reported in the PAR.

———— **Note** —————

- In conjunction with the requirements in *Non-cacheable accesses and instruction caches*, the requirements in this section mean the architecturally required effect of `SCTLR_ELx.I` is limited to its effect on caching instruction accesses in unified caches.
- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in *Mismatched memory attributes on page B2-105* must be followed to manage the corresponding loss of coherency.

D3.4.5 Behavior of caches at reset

In ARMv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in *Enabling and disabling the caching of memory accesses on page D3-1696* reset to values that force all memory locations to be treated as Non-cacheable.

———— **Note** —————

This applies only to the controls that apply to the Translation regime that is used by the Exception level and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
 - Provide a mechanism to ensure the correct initialization of the caches.
 - Be documented clearly as part of the documentation of the device.

In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.

- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

See also *TLB behavior at reset on page D4-1813*.

D3.4.6 Non-cacheable accesses and instruction caches

In AArch64 state, instruction accesses to Non-cacheable Normal memory can be held in instruction caches.

Correspondingly, the sequence for ensuring that modifications to instructions are available for execution must include invalidation of the modified locations from the instruction cache, even if the instructions are held in Normal Non-cacheable memory. This includes cases where System register Cacheability control fields force instruction accesses to memory to be Non-cacheable.

Therefore when using self-modified code in non-cacheable space in a uniprocessor system, the following sequence is required:

```
; Enter this code with <Wt> containing the new 32-bit instruction
; to be held at a location pointed to by <Xn> in Normal Non-cacheable memory.
STR <Wt>, [Xn]
DSB ISH; Ensure visibility of the data stored
IC IVAU, [Xn] ; Invalidate instruction cache by VA to PoU
DSB ISH; Ensure completion of the invalidations
ISB ;
```

In a multiprocessor system, the **IC IVAU** is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence, but additional software steps might be required to synchronize the threads with other PEs. This might be necessary so that the PEs executing the modified instructions can execute an ISB after completing the invalidation, and to avoid issues associated with concurrent modification and execution of instruction sequences.

Larger blocks of instructions can be modified using the **IC IALLU** instruction for a uniprocessor system, or a **IC IALLUIS** for a multiprocessor system.

———— **Note** —————

This section applies even when the Cacheability control fields force instruction accesses to memory in AArch64 state to be Non-cacheable, as described in *Enabling and disabling the caching of memory accesses* on page D3-1696.

D3.4.7 About cache maintenance in ARMv8

The following sections give general information about cache maintenance:

- *Terms used in describing the maintenance instructions.*
- *The ARMv8 abstraction of the cache hierarchy* on page D3-1702.

The following sections describe cache maintenance instruction:

- *Instruction cache maintenance instructions (IC*)* on page D3-1704.
- *Data cache maintenance instructions (DC*)* on page D3-1704.

———— **Note** —————

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the **SCTLR_EL1**.{I, C} controls.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- *Terminology for cache maintenance instruction operating by virtual address, VA* on page D3-1700.
- *Terminology for cache maintenance instructions operating by set/way* on page D3-1700.
- *Terminology for Clean, Invalidate, and Clean and Invalidate instructions* on page D3-1701.

Terminology for cache maintenance instruction operating by virtual address, VA

The addresses used by the PE are VAs. When all applicable stages of translation are disabled, the virtual address is identical to the physical address.

———— Note ————

For more information about memory system behavior when address translation is disabled, see [The effects of disabling a stage of address translation on page D4-1767](#).

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space Identifier*, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine Identifier*, VMID.

For a data or unified cache maintenance instruction by VA, the operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault cases described in:

- [Data cache maintenance instructions \(DC*\) on page D3-1704](#).
- [Stage 2 fault on a stage 1 translation table walk on page D4-1806](#).

For an instruction cache maintenance instruction by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Permission fault, except for the Permission fault case described in [Stage 2 fault on a stage 1 translation table walk on page D4-1806](#).

For more information about these faults, see [MMU faults on page D4-1800](#).

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

- Level** The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the [CLIDR_EL1](#).
- In the ARM architecture, the lower numbered cache levels are those closest to the PE. See [Memory hierarchy on page B2-71](#).
- Set** Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.
- In the ARM architecture, sets are numbered from 0.
- Way** The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.
- In the ARM architecture, ways are numbered from 0.

———— Note ————

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

———— **Note** —————

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.
- For instruction operating by VA, two conceptual points are defined:

Point of Coherency (PoC)

For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

———— **Note** —————

The presence of system caches can affect the definition of point of coherency as described in [System level caches on page D3-1713](#).

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR_EL1](#) relate to these conceptual points:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see [CLIDR_EL1, Cache Level ID Register on page D7-1912](#).

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by address on page D3-1703](#).
- [Cache maintenance instructions that operate by set/way on page D3-1703](#).

Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See [Terms used in describing the maintenance instructions on page D3-1699](#) for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

[Cache maintenance instructions](#) lists the address-based maintenance instructions.

The `CTR_EL0` holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the `CTR_EL0` defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

[Cache maintenance instructions](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

D3.4.8 Cache maintenance instructions

The A64 cache maintenance instructions are part of the A64 system instruction class in the register encoding space. For encoding details and other general information on these system instruction, see [System instructions on page C3-144](#), [SYS on page C6-742](#) and [Cache maintenance instructions, and data cache zero on page C5-276](#).

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. [Table D3-3](#) shows these system instructions. Instructions that take an argument include Xt in the instruction description.

————— Note —————

In [Table D3-3](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.

Table D3-3 System instructions for cache maintenance

| System instructions | Instruction | Notes |
|--|---|---|
| Instruction cache maintenance instructions, see System instructions on page C3-144 | | |
| IC IALLUIS | Invalidate all to Point of Unification, Inner Shareable | EL1 or higher access. |
| IC IALLU | Invalidate all to Point of Unification | EL1 or higher access. |
| IC IVAU, Xt | Invalidate by virtual address to Point of Unification | When <code>SCTLR_EL1.UCI == 1</code> , EL0 access. Otherwise, EL1 or higher access. |

Table D3-3 System instructions for cache maintenance (continued)

| System instructions | Instruction | Notes |
|---|---|---|
| Data cache maintenance instructions, see System instructions on page C3-144 | | |
| DC IVAC , Xt | Invalidate by virtual address to Point of Coherency | EL1 or higher access. |
| DC ISW , Xt | Invalidate by set/way | EL1 or higher access. |
| DC CVAC , Xt | Clean by virtual address to Point of Coherency | When SCTLR_EL1.UCI == 1 , EL0 access. Otherwise EL1 or higher access. |
| DC CSW , Xt | Clean by set/way | EL1 or higher access. |
| DC CVAU , Xt | Clean by virtual address to Point of Unification | When SCTLR_EL1.UCI == 1 , EL0 access. Otherwise EL1 or higher access. |
| DC CIVAC , Xt | Clean and invalidate by virtual address to Point of Coherency | When SCTLR_EL1.UCI == 1 , EL0 access. Otherwise EL1 or higher access. |
| DC CISW , Xt | Clean and invalidate by set/way | EL1 or higher access. |

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

The following subsections give more information about these instructions:

- [Instruction cache maintenance instructions \(IC*\)](#).
- [Data cache maintenance instructions \(DC*\)](#).
- [EL0 accessibility to cache maintenance instructions on page D3-1705](#).
- [General requirements for the scope of maintenance instructions on page D3-1705](#).
- [Effects of instructions that operate by VA to the Point of Coherency on page D3-1706](#).
- [Effects of instructions operate by VA but not to the Point of Coherency on page D3-1706](#).
- [Effects of All and set/way maintenance instructions on page D3-1707](#).
- [Effects of virtualization and security on the cache maintenance instructions on page D3-1707](#).
- [Boundary conditions for cache maintenance instructions on page D3-1708](#).
- [Ordering and completion of data and instruction cache instructions on page D3-1709](#).
- [Performing cache maintenance instructions on page D3-1710](#).

Instruction cache maintenance instructions (IC*)

The A64 assembly syntax for these instructions is described in [System instructions on page C3-144](#).

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No restrictions apply for this address.

See also [EL0 accessibility to cache maintenance instructions on page D3-1705](#) and [Ordering and completion of data and instruction cache instructions on page D3-1709](#).

Data cache maintenance instructions (DC*)

The A64 assembly syntax for these instructions is described in [System instructions on page C3-144](#).

Where an address argument for these instructions is required, it takes the form of a 64-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 64-bit register, the upper 32 bits of which are RES0.

[DC IVAC](#) requires write permission or else a Permission fault is generated.

A [DC IVAC](#) or [DC ISW](#) executed at Non-secure EL1 is performed by the PE as clean and invalidate, that is as a [DC CIVAC](#) or [DC CISW](#), if both of the following apply:

- EL2 is implemented.
- [HCR_EL2.VM](#) is set to 1, meaning the second stage of address translation is enabled.

———— **Note** —————

This also applies to the AArch32 cache maintenance instructions [DCIMVAC](#) and [DCISW](#). see [AArch32 data cache maintenance instructions \(DC*\)](#) on page G3-4001.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is `CONSTRAINED UNPREDICTABLE`, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions](#) on page K1-5492 or the instruction description.

If a memory fault that sets the [FAR](#) for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the [FAR](#) holds the address specified in the register argument of the instruction.

———— **Note** —————

Despite its mnemonic, [DC ZVA](#) is not a cache maintenance instruction. For more information, see [DC ZVA, Data Cache Zero by VA](#) on page C5-359.

See also [EL0 accessibility to cache maintenance instructions](#) and [Ordering and completion of data and instruction cache instructions](#) on page D3-1709.

EL0 accessibility to cache maintenance instructions

The [SCTLR_EL1.UCI](#) bit enables EL0 access for the [DC CVAU](#), [DC CVAC](#), [DC CIVAC](#), and [IC IVAU](#) instructions. When EL0 use of these instructions is disabled because [SCTLR_EL1.UCI](#) == 0, executing one of these instructions at EL0 generates a trap to EL1, that is reported using `EC = 0x18`.

For these instructions read access permission is required. When the value of [SCTLR_EL1.UCI](#) is 1:

- For the [DC CVAU](#), [DC CVAC](#), and [DC CIVAC](#) instructions, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, a Permission fault is generated.
- For the [IC IVAU](#) instruction, if the instruction is executed at EL0 and the address specified in the argument cannot be read at EL0, it is `IMPLEMENTATION DEFINED` whether a Permission fault is generated.

Software can read the [CTR_EL0](#) to discover the stride needed for cache maintenance instructions. The [SCTLR_EL1.UCT](#) bit enables EL0 access to the [CTR_EL0](#). When EL0 access to the Cache Type register is disabled, a register access instruction executed at EL0 is trapped to EL1 using `EC = 0x18`.

General requirements for the scope of maintenance instructions

The ARMv8 specification of the cache maintenance instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in [General behavior of the caches](#) on page D3-1693, [Behavior of caches at reset](#) on page D3-1698, and [Preloading caches](#) on page B2-74.

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

———— **Note** —————

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by VA to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the shareability domain described by the shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table D3-4 shows the scope of the Data and unified cache maintenance instructions.

Table D3-4 PEs affected by cache maintenance instructions to the Point of Coherency

| Shareability | PEs affected | Effective to |
|-----------------|--|---|
| Non-shareable | The PE performing the operation | The Point of Coherency of the entire system |
| Inner Shareable | All PEs in the same Inner Shareable shareability domain as the PE performing the operation | The Point of Coherency of the entire system |
| Outer Shareable | All PEs in the same Outer Shareable shareability domain as the PE performing the operation | The Point of Coherency of the entire system |

Effects of instructions operate by VA but not to the Point of Coherency

For these instructions, Table D3-5 shows how, for a VA in a Normal or Device memory location, the shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table D3-5 PEs affected by cache maintenance instructions to the Point of Unification

| Shareability | PEs affected | Effective to |
|------------------------------------|---|--|
| Non-shareable | The PE executing the instruction | The point of unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction |
| Inner Shareable or Outer Shareable | All PEs in the same Inner Shareable shareability domain as the PE executing the instruction | The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain as the PE executing the instruction |

———— **Note** —————

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable shareability domain containing the PE executing the instruction.

Effects of All and set/way maintenance instructions

The **IC IALLU** and **DC** set/way instructions apply only to the caches of the PE that performs the instruction.

The **IC IALLUIS** instruction can affect the caches of all PEs in the same Inner Shareable shareability domain as the PE that performs the instruction. This instruction has an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable shareability domain.

———— Note —————

The possible presence of system caches, as described in [System level caches on page D3-1713](#), means architecture does not guarantee that all levels of the cache can be maintained using set/way instructions.

Effects of virtualization and security on the cache maintenance instructions

Each Security state has its own physical address (PA) space, therefore cache entries are associated with PA space.

[Table D3-6](#) shows the effects of virtualization and security on the cache maintenance instructions. In the table, the *Specified entries* are entries that the architecture requires the instruction to affect. The rules described in [General behavior of the caches on page D3-1693](#) mean that an instruction might also affect other entries.

Table D3-6 Effects of virtualization and security on the maintenance instructions

| Cache maintenance instructions | Security state | Specified entries |
|--|----------------|--|
| Data or unified cache maintenance instructions | | |
| Invalidate, Clean, or Clean and Invalidate by VA: IVAC, CVAC, CVAU, CIVAC | Both | All lines that hold the PA that, in the current Security state, is mapped to by the combination of all of: <ul style="list-style-type: none"> The specified VA. For an instruction executed at EL1 or EL0, the current ASID if the location is mapped to by a non-global page. For an instruction executed at Non-secure EL1 or Non-secure EL0, the current VMID^a. |
| Invalidate, Clean, or Clean and Invalidate by set/way: ISW, CSW, CISW | Non-secure | Line specified by set/way provided that the entry comes from the Non-secure PA space. |
| | Secure | Line specified by set/way regardless of the PA space that the entry has come from. |
| Instruction cache maintenance instructions | | |
| Invalidate by VA: IVAU | Both | All lines corresponding to the specified VA ^b in the current translation regime and: <ul style="list-style-type: none"> For an instruction executed at EL1 or EL0, the current ASID. For an instruction executed at Non-secure EL1 or Non-secure EL0, the current VMID^a. |
| Invalidate All: IALLU, IALLUIS | Both | For an instruction executed at: <ul style="list-style-type: none"> Non-secure EL1, all instruction cache lines containing entries associated with the current VMID^a. EL2, all instruction cache lines containing Non-secure entries. EL3 or Secure EL1, all instruction cache lines. |

a. Dependencies on the VMID apply even when [HCR_EL2.VM](#) is set to 0. The architecture does not define a reset value for [VTBR_EL2.VMID](#), and therefore, in any implementation that includes EL2, the boot software executed when reset is deasserted must initialize [VTBR_EL2.VMID](#).

- b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:
- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
 - For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.
 - For an ASID and VMID tagged VIVT instruction cache, the cache maintenance applies to entries whose virtual address corresponds to the specified address.

For information on types of instruction cache see [Instruction caches on page D4-1829](#).

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in [The interaction of cache lockdown with cache maintenance instructions on page D3-1712](#) applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.
- The AArch64 Data cache invalidate instructions, [DC IVAC](#) and [DC ISW](#), at EL1 and EL0, and the AArch32 Data cache invalidate instructions [DCIMVAC](#) and [DCISW](#), at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
 - The value of [HCR.VM](#) is 1.
 - The instruction is executed in Non-secure state, or EL3 is not implemented.

The means that, in Non-secure state:

- At EL1 using AArch64 or EL0 using AArch64, a [DC IVAC](#) instruction operates as [DC CIVAC](#), and a [DC ISW](#) instruction operates as [DC CISW](#).
- At EL1 using AArch32, a [DCIMVAC](#) instruction operates as [DCCIMVAC](#), and a [DCISW](#) instruction operates as [DCCISW](#).

- The AArch64 Data cache invalidate by set/way instruction [DC ISW](#), at EL1 and EL0, and the AArch32 Data cache invalidate by set/way instruction [DCISW](#), at EL1, perform a cache clean as well as a cache invalidation if both of the following apply:
 - The value of [HCR_EL2.SWIO](#) is 1.
 - The instruction is executed in Non-secure state, or EL3 is not implemented.

This means that, in Non-secure state:

- At EL1 using AArch64 or EL0 using AArch64, a [DC ISW](#) instruction operates as [DC CISW](#).
- At EL1 using AArch32, a [DCISW](#) instruction operates as [DCCISW](#).

- When the value of [HCR_EL2.FB](#) is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch64, this applies to the [TLBI VMALLE1](#), [TLBI VAE1](#), [TLBI ASIDE1](#), [TLBI VAAE1](#), [TLBI VALE1](#), [TLBI VAALE1](#), and [IC IALLU](#) instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example [IC IALLU](#) is upgraded to [IC IALLUIS](#).

For more information about the cache maintenance instructions, see [About cache maintenance in ARMv8 on page D3-1699](#), [Cache maintenance instructions on page D3-1703](#), and [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
 - Is Normal memory or Device memory.
 - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering and completion of data and instruction cache instructions

All data cache instructions, other than [DC ZVA](#), that specify an address:

- Execute in program order relative to loads or stores that access an address in Normal memory with either Inner Write Through or Inner Write Back attributes within the same cache line of minimum size, as indicated by [CTR_EL0.DMinLine](#).
- Can execute in any order relative to loads or stores that access any address with the Device memory attribute, or with Normal memory with Inner Non-cacheable attribute unless a DMB or DSB is executed between the instructions.
- Execute in program order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address within the same cache line of minimum size, as indicated by [CTR_EL0.DMinLine](#).
- Can execute in any order relative to loads or stores that access an address in a different cache line of minimum size, as indicated by [CTR_EL0.DMinLine](#), unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to other data cache maintenance instructions, other than DC ZVA, that specify an address in a different cache line of minimum size, as indicated by [CTR_EL0.DMinLine](#), unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

Note

- Data cache ordering rules by address are consistent with physically indexed physically tagged caches. See [Data and unified caches on page D4-1829](#).
 - [Data cache zero instruction on page D3-1711](#) describes the ordering and completion rules for Data Cache Zero.
-

All data cache maintenance instructions that do not specify an address:

- Can execute in any order relative to data cache maintenance instructions that do not specify an address unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to data cache maintenance instructions that specify an address, other than Data Cache Zero, unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to loads or stores unless a DMB or DSB is executed between the instructions.
- Can execute in any order relative to instruction cache maintenance instructions unless a DSB is executed between the instructions.

All instruction cache instructions can execute in any order relative to other instruction cache instructions, data cache instructions, loads, and stores unless a DSB is executed between the instructions.

A cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

In all cases, where the text in this section refers to a DMB or a DSB, this means a DMB or DSB whose required access type is both loads and stores.

———— **Note** —————

These ordering requirements are extended from the requirements in AArch32 state given:

- [Ordering of cache and branch predictor maintenance instructions on page G3-4007.](#)
- [AArch32 instruction cache maintenance instructions \(IC*\) on page G3-4001.](#)

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the `CTR_EL0.DMinLine` value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the `CTR_EL0.IMinLine` value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

———— **Note** —————

Since the set/way instructions are performed only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Since any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches on page D3-1713](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```
MRS    X0, CLIDR_EL1
AND    W3, W0, #0x07000000    // Get 2 x Level of Coherence
LSR    W3, W3, #23
CBZ    W3, Finished
```

```

MOV    W10, #0           // W10 = 2 x cache level
MOV    W8, #1            // W8 = constant 0b1
Loop1: ADD    W2, W10, W10, LSR #1 // Calculate 3 x cache level
      LSR    W1, W0, W2 // extract 3-bit cache type for this level
      AND    W1, W1, #0x7
      CMP    W1, #2
      B.LT   Skip // No data or unified cache at this level
      MSR    CSSELR_EL1, X10 // Select this cache level
      ISB // Synchronize change of CSSELR
      MRS    X1, CCSIDR_EL1 // Read CCSIDR
      AND    W2, W1, #7 // W2 = log2(lineLen)-4
      ADD    W2, W2, #4 // W2 = log2(lineLen)
      UBFX   W4, W1, #3, #10 // W4 = max way number, right aligned
      CLZ    W5, W4 // W5 = 32-log2(ways), bit position of way in DC operand
      LSL    W9, W4, W5 // W9 = max way number, aligned to position in DC operand
      LSL    W16, W8, W5 // W16 = amount to decrement way number per iteration
Loop2: UBFX   W7, W1, #13, #15 // W7 = max set number, right aligned
      LSL    W7, W7, W2 // W7 = max set number, aligned to position in DC operand
      LSL    W17, W8, W2 // W17 = amount to decrement set number per iteration
Loop3: ORR    W11, W10, W9 // W11 = combine way number and cache number ...
      ORR    W11, W11, W7 // ... and set number for DC operand
      DC    CSW, X11 // Do data cache clean by set and way
      SUBS   W7, W7, W17 // Decrement set number
      B.GE   Loop3
      SUBS   X9, X9, X16 // Decrement way number
      B.GE   Loop2
Skip:  ADD    W10, W10, #2 // Increment 2 x cache level
      CMP    W3, W10
      DSB // Ensure completion of previous cache maintenance instruction
      B.GT   Loop1
Finished:

```

Similar approaches can be used for all cache maintenance instructions.

D3.4.9 Data cache zero instruction

The Data Cache Zero by Address instruction, **DC ZVA**, writes 0b00 to each of a block of N bytes, aligned in memory to N bytes in size, where the block in memory is identified by the address passed. There are no alignment restrictions on the address supplied. The **DCZID_ELO** register indicates the block size that is written with byte values of zero.

Software can restrict access to this operation. See *Configurable instruction enables and disables, and trap controls on page D1-1562*.

If disabled, the operation at EL0 is trapped to EL1.

The DC ZVA instruction behaves as a set of stores to the location being accessed, and:

- Generates a Permission fault if the translation regime being used when the instruction is executed does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instruction.

In addition:

- When the instruction is executed, it can generate memory faults or watchpoints that are prioritized in the same way as other memory related faults or watchpoints. Where a synchronous Data Abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set to 1, which would be the case for all other cache maintenance instructions. See *Exception from a Data abort on page D1-1533* for more information about the encoding of **ESR_ELx** and the associated ISS field.
- If the memory region being zeroed is any type of Device memory, then DC ZVA generates an Alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

———— **Note** ————

The architecture makes no statements about whether or not a [DC ZVA](#) instruction causes allocation to any particular level of the cache, for addresses that have a cacheable attribute for those levels of cache.

D3.4.10 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
 - Cache clean by set/way, [DC CSW](#).
 - Cache invalidate by set/way, [DC ISW](#).
 - Cache clean and invalidate by set/way, [DC CISW](#).
 - Instruction cache invalidate all, [IC IALLU](#) and [IC IALLUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [Exception from a Data abort on page D1-1533](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DC CVAC](#) and [DC CVAU](#).
- Cache invalidate by virtual address, [DC IVAC](#).
- Cache clean and invalidate by virtual address, [DC CIVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [ESR_ELx on page K12-5663](#).

In an implementation that includes EL2, if [HCR_EL2.TIDCP](#) is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

———— **Note** ————

An implementation that uses an abort mechanisms for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED spaces reserved for Cache Lockdown, see [Reserved encodings for IMPLEMENTATION DEFINED registers on page C5-291](#).

D3.4.11 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches*.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by any cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entirety of such a cache must be performed, as in the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to the software. The management of such caches is outside the scope of the architecture.

D3.4.12 Branch prediction

ARMv8 does not define any branch predictor maintenance instructions for AArch64 state.

If branch prediction is architecturally visible, cache maintenance must also apply to branch prediction.

D3.5 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or debug logic. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of the following:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page D1-1499](#).

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous external aborts.

VMSAv8-64 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported. Asynchronous aborts are taken as SError interrupt exceptions. See [Asynchronous exception types, routing, masking and priorities on page D1-1555](#).

Synchronous external aborts are reported using the Instruction Abort and Data Abort exceptions. See [Synchronous exception types, routing and priorities on page D1-1547](#).

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running, ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- [External abort on an instruction fetch](#).
- [External abort on data read or write](#).
- [Provision for the classification of external aborts](#).
- [Parity or ECC error reporting on page D3-1715](#).

D3.5.1 External abort on an instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous.

A synchronous external abort on an instruction fetch is taken precisely using the Instruction Abort exception.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.2 External abort on data read or write

Externally-generated errors that occur during a data read or write can be either synchronous or asynchronous.

A synchronous external abort on a data read or write is taken precisely using the Data Abort exception.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation the abort is taken using the SError interrupt exception.

D3.5.3 Provision for the classification of external aborts

In AArch64 state, an implementation can use `ESR_ELx.EA, ISS[9]`, to provide more information about synchronous external aborts. For more information, see [Exception from an Instruction abort on page D1-1533](#) and [Exception from a Data abort on page D1-1533](#).

For all aborts other than synchronous external aborts reported using the EC values `0x20`, `0x21`, `0x24`, and `0x25`, `ESR_ELx.EA, ISS[9]`, returns a value of 0.

D3.5.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache system. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1523](#). However, when parity or ECC error reporting is implemented, it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code or using another appropriate encoding.

For all purposes other than the fault status encoding, parity or ECC errors are treated as external aborts.

D3.6 Memory barrier instructions

[Memory barriers on page B2-87](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

D3.6.1 EL2 control of the shareability of data barrier instructions executed at Non-secure EL0 or EL1

In an implementation that includes EL2 and supports shareability limitations on the data barrier instructions, the [HCR_EL2.BSU](#) field can upgrade the required shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. [Table D3-7](#) shows the encoding of this field.

Table D3-7 EL2 control of shareability of barrier instructions executed at Non-secure EL0 or EL1

| HCR_EL2.BSU | Minimum shareability of barrier instructions |
|-----------------------------|--|
| 00 | No effect, shareability is as specified by the instruction |
| 01 | Inner Shareable |
| 10 | Outer Shareable |
| 11 | Full system |

For an instruction executed at EL0 or EL1 in Non-secure state, [Table D3-8](#) shows how the [HCR_EL2.BSU](#) is combined with the shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction.

Table D3-8 Effect of HCR_EL2.BSU on barrier instructions executed at Non-secure EL1 or EL0

| Shareability specified by the DMB or DSB argument | HCR_EL2.BSU | Resultant shareability |
|---|-----------------------------|------------------------|
| Full system | Any | Full system |
| | 00, 01, or 10 | Outer Shareable |
| Outer Shareable | 11, Full system | Full system |
| | 00 or 01 | Inner Shareable |
| | 10, Outer Shareable | Outer Shareable |
| Inner Shareable | 11, Full system | Full system |
| | 00, No effect | Non-shareable |
| | 01, Inner Shareable | Inner Shareable |
| Non-shareable | 10, Outer Shareable | Outer Shareable |
| | 11, Full system | Full system |
| | 11, Full system | Full system |

D3.7 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions](#).
- [Basic memory access](#).
- [Aligned memory access](#).
- [Unaligned memory access](#) on page D3-1718.
- [Exclusive monitors operations](#) on page D3-1718.
- [Access permission checking](#) on page D3-1719.
- [Abort exceptions](#) on page D3-1719.
- [Memory barriers](#) on page D3-1719.

D3.7.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr_NC](#), [MemAttr_WT](#), and [MemAttr_WB](#) constants.
- Allocation hints, defined by the [MemHint_No](#), [MemHint_WA](#), [MemHint_RA](#), and [MemHint_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

These types are defined in [Chapter J1 ARMv8 Pseudocode](#).

D3.7.2 Basic memory access

The two `_Mem[]` accessors, Non-assignment (memory read) `_Mem[]` and Assignment (memory write) `_Mem[]`, are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using `desc.paddress` which supplies:

- A 48-bit physical address.
- A single NS bit to select between Secure and Non-secure parts of the array.

The `AccType` parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of `AccType`, see [Address space](#) on page B2-68.

The actual implemented array of memory might be smaller than the 2^{48} bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#) on page B2-94, [Memory ordering](#) on page B2-84, and [Atomicity in the ARM architecture](#) on page B2-81.

`PAMax()` returns the IMPLEMENTATION DEFINED size of the physical address. This function is defined in [Chapter J1 ARMv8 Pseudocode](#)

D3.7.3 Aligned memory access

The two `MemSingle[]` accessors, Non-assignment (memory read) `AArch64.MemSingle[]` and Assignment (memory write) `AArch64.MemSingle[]`, make atomic, little-endian accesses of size bytes. These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

D3.7.4 Unaligned memory access

The two Mem[] accessors, Non-assignment (memory read) Mem[] and Assignment (memory write) Mem[], make accesses of the required type. If an access is not architecturally defined to be atomic, Mem[] synthesizes accesses from multiple calls to AArch64.MemSingle[]. It also reverses the byte order if the access is big-endian.

The AArch64.CheckAlignment() function checks the alignment of memory accesses.

D3.7.5 Exclusive monitors operations

The AArch64.SetExclusiveMonitors() function sets the exclusive monitors for a block of bytes, the size of which is determined by size, at the virtual address defined by address.

The AArch64.ExclusiveMonitorsPass() function checks whether the exclusive monitors are set to include the location of a number of bytes specified by size, at the virtual address defined by address. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return FALSE if the virtual address is not the same as that used in the previous call to AArch64.SetExclusiveMonitors().

The ExclusiveMonitorsStatus() function returns 0 if the previous atomic write was to the same physical memory locations selected by AArch64.ExclusiveMonitorsPass() and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The MarkExclusiveGlobal() procedure takes as arguments a FullAddress address, the PE identifier processorid and the size of the transfer. The procedure records that the PE processorid has requested exclusive access covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONSTRAINED UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The MarkExclusiveLocal() procedure takes as arguments a FullAddress address, the PE identifier processorid and the size of the transfer. The procedure records in a local record that PE processorid has requested exclusive access to an address covering at least size bytes from address paddress. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a MarkExclusiveGlobal() using the same parameters.

The IsExclusiveGlobal() function takes as arguments a FullAddress address, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked in a global record an address range as exclusive access requested that covers at least size bytes from address paddress. It is IMPLEMENTATION DEFINED whether it returns TRUE or FALSE if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, IsExclusiveGlobal() returns FALSE.

The IsExclusiveLocal() function takes as arguments a FullAddress address, the PE identifier processorid and the size of the transfer. The function returns TRUE if the PE processorid has marked an address range as exclusive access requested that covers at least the size bytes from address paddress. It is IMPLEMENTATION DEFINED whether this function returns TRUE or FALSE if the address marked as exclusive access requested does not cover all of size bytes from address paddress. If no address is marked as exclusive access requested, then this function returns FALSE. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of IsExclusiveGlobal() with the same parameters.

The ClearExclusiveByAddress() procedure takes as arguments a FullAddress address, the PE identifier processorid and the size of the transfer. The procedure clears the global records of all PEs, other than processorid, for which an address region including any of size bytes starting from paddress has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE processorid is also cleared if any of size bytes starting from paddress has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The ClearExclusiveLocal() procedure takes as arguments the PE identifier processorid. The procedure clears the local record of PE processorid for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE processorid that an address has had a request for an exclusive access.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

D3.7.6 Access permission checking

The function `AArch64.CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors. It returns the result of the call to `AArch64.NoFault()`.

These functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

The interpretation of access permission is shown in [Memory access control on page D4-1783](#).

D3.7.7 Abort exceptions

The function `AArch64.Abort()` generates either a Data Abort or an Instruction Abort exception by calling `AArch64.DataAbort()` or `AArch64.InstructionAbort()`. It also can generate a debug exception for debug related faults, see [Chapter D2 AArch64 Self-hosted Debug](#).

The function `AArch64.DataAbort()` generates a Data Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, `ESR_ELx`. See [Exception from a Data abort on page D1-1533](#). A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.DataAbort()` also sets the FAR to the VA of the abort.

The function `AArch64.InstructionAbort()` generates an Instruction Abort exception, routes the exception to EL2 or EL3, and records the information required for the Exception Syndrome registers, `ESR_ELx`. See [Exception from an Instruction abort on page D1-1533](#). A second stage abort might also record the intermediate physical address, IPA, but this depends on the type of the abort.

For a synchronous abort, `AArch64.InstructionAbort()` also sets the FAR to the VA of the abort.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. [Pseudocode description of the MMU faults on page D4-1809](#) provides a number of wrappers to generate `FaultRecords`.

The function `AArch64.NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

D3.7.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier`, `DataSynchronizationBarrier`, and `InstructionSynchronizationBarrier` perform the memory barriers.

Chapter D4

The AArch64 Virtual Memory System Architecture

This chapter provides a system level view of the AArch64 *Virtual Memory System Architecture* (VMSAv8-64), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state. It contains the following sections:

- *About the Virtual Memory System Architecture (VMSA)* on page D4-1722.
- *The VMSAv8-64 address translation system* on page D4-1726.
- *VMSAv8-64 translation table format descriptors* on page D4-1774.
- *Memory access control* on page D4-1783.
- *Memory region attributes* on page D4-1792.
- *MMU faults* on page D4-1800.
- *Translation Lookaside Buffers (TLBs)* on page D4-1810.
- *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1815.
- *Caches in a VMSAv8-64 implementation* on page D4-1829.

D4.1 About the Virtual Memory System Architecture (VMSA)

This chapter describes the ARMv8 *Virtual Memory System Architecture* (VMSA), and in particular how it applies to a PE that is executing in AArch64 state. In this state the PE is using VMSAv8-64, as defined in [ARMv8 VMSA naming](#). See [The ARMv8 VMSA when some Exception levels are using AArch32](#) for information about the VMSA in other contexts.

A VMSA provides a *Memory Management Unit* (MMU), that controls address translation, access permissions, and memory attribute determination and checking, for memory accesses made by the PE. The process of address translation maps the *virtual addresses* (VAs) used by the PE onto the *physical addresses* (PAs) of the physical memory system. The mapping of a VA to a PA requires either a single stage of translation, or two sequential stages of translation.

The translations are defined independently for different Exception levels and Security states, as described in [The VMSAv8-64 address translation system on page D4-1726](#).

VMSAv8-64 supports tagging of VAs, as described in [Address tagging in AArch64 state on page D4-1724](#). As that section describes, this address tagging has no effect on the address translation process.

The remainder of this chapter gives a full description of VMSAv8-64 for an implementation that includes all of the Exception levels. [The implemented Exception levels and the resulting translation stages and regimes on page D4-1769](#) describes the differences in the VMSA if some Exception levels are not implemented.

D4.1.1 ARMv8 VMSA naming

The ARMv8 VMSA naming model reflects the possible stages of address translation, as follows:

- VMSAv8** The overall translation scheme, within which an address translation has one or two stages.
- VMSAv8-32** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch32.
VMSAv8-32 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch32.
- VMSAv8-64** The translation scheme for a single stage of address translation that is managed from an Exception level that is using AArch64.
VMSAv8-64 is sometimes used to refer to the two stages of translation used to map a VA to a PA, where each stage is managed from an Exception level that is using AArch64.

D4.1.2 The ARMv8 VMSA when some Exception levels are using AArch32

As stated at the start of the chapter, this chapter describes VMSAv8-64, the ARMv8 VMSA that applies to an Exception level that is using AArch64. However, when a higher Exception level is using AArch64, and therefore using VMSAv8-64, lower Exception levels can be using AArch32. [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes VMSAv8-32, meaning it describes:

- The translation stages and translation regimes when EL3 is using AArch32.
- Any stages of address translation that are using VMSAv8-32 when EL3 is using AArch64.

However, a PE can be executing at EL0 using AArch32 when EL1 is using AArch64. In this case the PE is using the VMSAv8-64 EL1&0 translation regime as described in [Constraints on accesses from EL0 when EL0 is using AArch32 on page D4-1728](#).

D4.1.3 VMSA address types and address spaces

A description of the VMSA refers to the following address types.

———— **Note** —————

These descriptions relate to the VMSAv8 description and therefore give more detail than the generic definitions given in the glossary.

———— **Virtual address (VA)** ————

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

———— **Note** —————

This means that an address held in the PC, LR, SP, or an ELR, is a VA.

In AArch64 state, a VA address space has a maximum address width of 48 bits. As [About address translation and supported input address ranges on page D4-1728](#) describes, a stage of address translation can support one or two VA ranges:

———— **Translation stage with a single VA range** ————

For a translation stage that supports a single VA range the 48-bit VA width gives a maximum VA space of 256TB, with VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFFFF.

———— **Translation stage with two VA ranges** ————

For a translation stage that supports two VA subranges, one at the bottom of the full 64-bit address range of the PC, and one at the top, as follows:

- The bottom VA range runs up from address 0x0000000000000000. With the maximum address width of 48 bits this gives a VA range of 0x0000000000000000 to 0x0000FFFFFFFFFFFFFF.
- The top VA subrange runs up to address 0xFFFFFFFFFFFFFFFF. With the maximum address width of 48 bits this gives a VA range of 0xFFFFFFFF000000000000 to 0xFFFFFFFFFFFFFFFF. Reducing the address width for this subrange increases the bottom address of the range.

This means that there are two VA subranges, each of up to 256TB.

Each translation regime that takes a VA as an input address can be configured to support fewer than 48 bits of VA space, see [Address size configuration on page D4-1731](#).

———— **Intermediate physical address (IPA)** ————

In a translation regime that provides two stages of address translation, the IPA is:

- The OA from the stage 1 translation.
- The IA for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA. Alternatively, the translation regime can be considered as having no concept of IPAs.

The IPA address space has a maximum address width of 48 bits, see [Address size configuration on page D4-1731](#).

———— **Physical address (PA)** ————

The address of a location in a physical memory map. That is, an output address from the PE to the memory system.

The EL3 and Secure EL1 Exception levels provide independent definitions of the PA spaces for Secure and Non-secure operation. This means they provide two independent address spaces, where:

- A VA accessed in Secure state can be translated to either the Secure or the Non-secure PA space.
- When in Non-secure state, a VA is always mapped to the Non-secure PA space.

Each PA address space has a maximum address width of 48 bits, but an implementation can implement fewer than 48 bits of PA. See [Address size configuration on page D4-1731](#).

D4.1.4 Address tagging in AArch64 state

In AArch64 state, the ARMv8 architecture supports the tagging of addresses. In these cases the top eight bits of the VA are ignored when determining:

- If the translation system is enabled, whether the address is out of range and therefore causes a Translation fault.
- If the translation system is not enabled, whether the address is out of range and therefore causes an Address size fault.
- Whether the address requires invalidation when performing a TLB invalidation instruction by address.

The use of address tags is controlled as follows:

For addresses using a stage 1 translation that supports two VA ranges

The value of bit[55] of the VA determines the register bit that controls the use of address tags, as follows:

- | | |
|-----------|---|
| VA[55]==0 | TCR_ELx.TBI0 determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address. |
| VA[55]==1 | TCR_ELx.TBI1 determines whether address tags are used. If stage 1 translation is enabled, TTBR1_ELx holds the base address of the translation tables used to translate the address. |

For addresses using a stage 1 translation that supports a single VA range

TCR_ELx.TBI determines whether address tags are used. If stage 1 translation is enabled, TTBR0_ELx holds the base address of the translation tables used to translate the address.

———— Note ————

The TCR_ELx.TBI_n or TCR_ELx.TBI bit determines whether address tags are used regardless of whether the corresponding translation regime is enabled.

An address tag enable bit also has an effect on the PC value in the following cases:

- Any branch or procedure return within the controlled Exception level.
- On taking an exception to the controlled Exception level, regardless of whether this is also the Exception level from which the exception was taken.
- On performing an exception return to the controlled Exception level, regardless of whether this is also the Exception level from which the exception return was performed.
- Exiting from debug state to the controlled Exception level.

———— Note ————

As an example of what is meant by the *controlled Exception level*, TCR_EL3.TBI controls this effect for:

- A branch or procedure return within EL3.
- Taking an exception to EL3.
- Performing an exception return or a debug state exit to EL3.

The effect of the controlling TBI{n} bit is:

For a translation regime where the stage 1 translation supports two VA ranges

If the controlling TBI{n} bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be a sign-extension of bit[55] of that address.

For a translation regime where the stage 1 translation supports a single VA range

If the controlling TBI bit for the address being loaded into the PC is set to 1, then bits[63:56] of the PC are forced to be 0x00.

The `AddrTop()` pseudocode function shows the algorithm determining the most significant bit of the VA, and therefore whether the VA is using tagging. For a translation regime where the stage 1 translation supports two VA ranges, this pseudocode includes the selection between `TTBR0_ELx` and `TTBR1_ELx` described in *Selection between TTBR0 and TTBR1 when two VA ranges are supported on page D4-1759*. See also *Relaxation of the tagged address handling requirements on an Illegal exception return*.

———— **Note** —————

The required behavior prevents a tagged address being propagated to the program counter.

When address tagging is enabled for an address that causes a Data Abort or a Watchpoint, the address tag is included in the VA returned in the FAR.

Relaxation of the tagged address handling requirements on an Illegal exception return

The `AddrTop()` pseudocode function does not cover a relaxation to the requirements for tagged address handling that applies to an Illegal exception return. In the case of an Illegal exception return, it is IMPLEMENTATION DEFINED whether the exception return targets:

- The Exception level indicated by the current `SPSR` at the time of the exception return.
- The Exception level at which the exception return instruction was executed.

The `AArch64.ExceptionReturn()` pseudocode function includes this IMPLEMENTATION DEFINED choice.

———— **Note** —————

- The `TCR_ELx.TBI{n}` fields have the effect shown in the `AArch64.ExceptionReturn()` pseudocode regardless of whether the corresponding translation regime is enabled.
- In the case of an Illegal exception return, the tag bits of the address can be propagated to the PC if all of the following apply:
 - The implementation treats the `target_exception_level` as being the Exception level that was described in the `SPSR` at the time of the exception return.
 - For the Exception level that was described in the `SPSR` at the time of the exception return, the value of the applicable `TCR_ELx.TBI{n}` field is 0.
 - In the Exception level that the exception was taken from, the value of the applicable `TCR_ELx.TBI{n}` field is 1.

In all other cases, the tag bits cannot be propagated to the PC.

D4.2 The VMSAv8-64 address translation system

The following subsections describe the VMSAv8-64 address translation system, that maps VAs to PAs:

- [About the VMSAv8-64 address translation system.](#)
- [Controlling address translation stages on page D4-1729.](#)
- [Memory translation granule size on page D4-1736.](#)
- [Translation tables and the translation process on page D4-1742.](#)
- [Overview of the VMSAv8-64 address translation stages on page D4-1745.](#)
- [The VMSAv8-64 translation table format on page D4-1756.](#)
- [The algorithm for finding the translation table descriptors on page D4-1763.](#)
- [The effects of disabling a stage of address translation on page D4-1767.](#)
- [The implemented Exception levels and the resulting translation stages and regimes on page D4-1769.](#)
- [Pseudocode description of VMSAv8-64 address translation on page D4-1769.](#)
- [Address translation instructions on page D4-1771.](#)

Related to this:

- [VMSAv8-64 translation table format descriptors on page D4-1774](#) describes the translation table entries.
- [Memory region attributes on page D4-1792](#) describes the attributes that are held in the translation table entries, including how different attributes can interact.
- [Translation Lookaside Buffers \(TLBs\) on page D4-1810](#) describes the caching of translation table lookups in TLBs, and the architected instructions for maintaining TLBs.
- [AArch64 Address translation examples on page K7-5552](#) gives detailed descriptions of typical examples of translating a VA to a final PA, and obtaining the memory attributes of that PA.

D4.2.1 About the VMSAv8-64 address translation system

The *Memory Management Unit* (MMU) controls address translation, memory access permissions, and memory attribute determination and checking, for memory accesses made by the PE.

The general model of MMU operation is that the MMU takes information about a required memory access, including an *input address* (IA), and either:

- Returns an associated *output address* (OA), and the *memory attributes* for that address.
- Is unable to perform the translation for one of a number of reasons, and therefore causes an exception to be generated. This exception is called an MMU fault. System registers are used to report any MMU faults that occur.

The process of mapping an IA to an OA is an *address translation*, or more precisely a single stage of address translation.

When using a VMSA, a *translation regime* maps a VA to a PA using one or two stages of translation, and:

- [The AArch64 translation regimes on page D4-1727](#) defines the translation regimes.
- [VMSA address types and address spaces on page D4-1723](#) give more information about VAs and PAs.

The *translation granule* specifies the granularity of the mapping from IA to OA. That is, it defines both:

- The *page size* for a stage of address translation, where a page is the smallest block of memory for which an IA to OA mapping can be specified.
- The size of a complete translation table for that stage of address translation.

The MMU is controlled by System registers, that provide independent control of each address translation stage, including a control to disable the stage of address translation. [The effects of disabling a stage of address translation on page D4-1767](#) defines how the MMU handles an access for which a required address translation stage is disabled.

This section describes the address translation system for an implementation that includes all of the Exception levels, and gives a complete description of translations that are controlled by an Exception level that is using AArch64. In addition:

- [The ARMv8 VMSA when some Exception levels are using AArch32 on page D4-1722](#) gives information about the VMSA when some Exception levels are using AArch32.
- [The implemented Exception levels and the resulting translation stages and regimes on page D4-1769](#) describes the effect on the address translation model when some Exception levels are not implemented.

Each enabled stage of address translation uses a set of address translations and associated memory properties held in memory mapped tables called *translation tables*. A single translation table lookup can resolve only a limited number of bits of the IA, and therefore a single address translation can require multiple lookups. These are described as different *levels* of lookup.

Translation table entries can be cached in a *Translation Lookaside Buffer* (TLB).

As well as defining the OA that corresponds to the IA, the translation table entries define the following properties:

- For accesses made from Secure state, whether the access is to the Secure or Non-secure address map.
- Memory access permissions.
- Memory region attributes.

For more information, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1778](#).

The following subsections give more information:

- [The AArch64 translation regimes](#).
- [About address translation and supported input address ranges on page D4-1728](#).
- [The VMSAv8-64 translation table format on page D4-1729](#).

The AArch64 translation regimes

The architecture defines a number of *translation regimes*, where a translation regime comprises either:

- A single stage of address translation.
This maps an input VA to an output PA.
- Two, sequential, stages of address translation, where:
Stage 1 maps an input VA to an output IPA.
— Stage 2 maps an input IPA to an output PA.

[Figure D4-1](#) shows these translation stages and translation regimes when EL3 is using AArch64.

Translation regimes, when EL3 is using AArch64

Figure D4-1 VMSAv8 AArch64 translation regimes, translation stages, and associated controls

This means that in VMSAv8-64 the set of translation regimes is:

The Secure EL3 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

The Non-secure EL2 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports a single VA range.

The Secure EL1&0 translation regime

This has a single stage of translation, stage 1, that maps VAs to PAs and supports two VA ranges and the use of ASIDs.

The Non-secure EL1&0 translation regime

If cached in a TLB, a translation table lookup for this regime is associated with the VMID that identifies the current *virtual machine*. This regime has two stages of lookup:

Stage 1 Maps VAs to IPAs. This stage supports two VA ranges and the use of ASIDs.

Stage 2 Maps IPAs to PAs. This stage supports a single IPA range.

An MMU fault might be generated by a particular stage of translation. An MMU fault is described as either a stage 1 MMU fault or a stage 2 MMU fault.

Note

- In the ARM architecture, a software agent, such as an operating system, that uses or defines stage 1 memory translations, might be unaware of the second stage of translation, and of the distinction between IPA and PA.
- A more generalized description of the translation regimes is that a regime always comprises two sequential stages of translation, but in some regimes the stage 2 translation both:
 - Returns an OA that equals the IA. This is called a *flat mapping* of the IA to the OA.
 - Does not change the memory attributes returned by the stage 1 address translation.

Constraints on accesses from EL0 when EL0 is using AArch32

ARMv8 permits execution with EL1 using AArch64 and EL0 using AArch32. In this case, accesses from EL1 and from EL0 are using the VMSAv8-64 EL1&0 translation regime, but when the PE is executing at EL0 using AArch32 it is using the AArch32 memory model. In particular, this means it is limited to a 32-bit VA range.

About address translation and supported input address ranges

For a single stage of address translation, a *Translation table base register (TTBR)* indicates the start of the first translation table required for a mapping from input address (IA) to output address (OA). For a stage of address translation that supports two VA ranges each VA range is an independent mapping from IA to OA. This means that each implemented translation stage shown in *VMSAv8 AArch64 translation regimes, translation stages, and associated controls on page D4-1727* requires:

- Two associated sets of translation tables if it supports two IA ranges.
- One associated set of translation tables if it supports a single IA range.

Note

- Stage 2 translations never support two IA ranges. This means that, for the translation stages that support two IA ranges the IA is always a VA,
- *Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls on page D4-1760* shows how two supported VA ranges might be used.

Controlling address translation stages on page D4-1729 summarizes the System registers that control address translation by the MMU, and *Selection between TTBR0 and TTBR1 when two VA ranges are supported on page D4-1759* gives more information about the address translation stages that support two VA ranges.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single IA to OA translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The high bits of the required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation table entries can be cached in a *Translation Lookaside Buffer*, see [Translation Lookaside Buffers \(TLBs\)](#) on page D4-1810.

The VMSAv8-64 translation table format

Stages of address translation that are controlled by an Exception level that is using AArch64 use the VMSAv8-64 translation table format. This format uses 64-bit descriptor entries in the translation tables.

———— Note —————

This format is an extension of the VMSAv8-32 Long-descriptor translation table format originally defined by the ARMv7 Large Physical Address Extension, and extended slightly by ARMv8. VMSAv8-32 also supports a Short-descriptor translation table format. [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes both of these formats.

The VMSAv8-64 translation table format provides:

- Up to four levels of address lookup.
- Input addresses of up to 48 bits.
- Output addresses of up to 48 bits.
- A translation granule size of 4KB, 16KB, or 64KB.

D4.2.2 Controlling address translation stages

[The implemented Exception levels and the resulting translation stages and regimes](#) on page D4-1769 defines the translation regimes and stages. For each supported address translation stage:

- A System register bit enables the stage of address translation.
- A System register bit determines the endianness of the translation table lookups.
- A *Translation Control Register (TCR_ELx)* controls the stage of address translation.
- If a stage of address translation supports two VA ranges then that stage of translation provides a **TTBR** for each VA range, and the stage of address translation has:
 - A single **TCR**.
 - A **TTBR** for each VA range. **TTBR0** points to the translation tables for the address range that starts at 0x0000000000000000, and **TTBR1** points to the translation tables for the address range that ends at 0xFFFFFFFFFFFFFFFF.

Otherwise, a single **TTBR** holds the address of the translation table that must be used for the first lookup for the stage of address translation.

For address translation stages controlled from AArch64:

- [Table D4-1](#) shows the endianness bit (EE) and the enable bit (M or VM) for each stage of address translation. Each register entry in the table gives the endianness bit followed by the enable bit.

Table D4-1 Enable and endianness bits for the AArch64 translation stages

| Translation stage | Controlled from | Controlling register |
|--------------------------|-----------------|--------------------------|
| Secure EL3 stage 1 | EL3 | SCTLR_EL3.{EE, M} |
| Secure EL1&0 stage 1 | Secure EL1 | SCTLR_EL1.{EE, M} |
| Non-secure EL2 stage 1 | EL2 | SCTLR_EL2.{EE, M} |
| Non-secure EL1&0 stage 2 | EL2 | SCTLR_EL2.EE, HCR_EL2.VM |
| Non-secure EL1&0 stage 1 | Non-secure EL1 | SCTLR_EL1.{EE, M} |

Note

If the **PA** of the software that enables or disables a particular stage of address translation differs from its **VA**, speculative instruction fetching can cause complications. ARM strongly recommends that the **PA** and **VA** of any software that enables or disables a stage of address translation are identical if that stage of translation controls translations that apply to the software currently being executed.

- [Table D4-2](#) shows the **TCR** and **TTBR**, or **TTBRs**, for each stage of address translation. In the table, each *Controlling registers* entry gives the **TCR** followed by the **TTBR** or **TTBRs**.

Table D4-2 TCrs and TTBRs for the AArch64 translation stages

| Translation stage | Controlled from | Controlling registers |
|--------------------------|-----------------|-------------------------------|
| Secure EL3 stage 1 | EL3 | TCR_EL3, TTBR0_EL3 |
| Secure EL1&0 stage 1 | Secure EL1 | TCR_EL1, TTBR0_EL1, TTBR1_EL1 |
| Non-secure EL2 stage 1 | EL2 | TCR_EL2, TTBR0_EL2 |
| Non-secure EL1&0 stage 2 | EL2 | VTCR_EL2, VTTBR_EL2 |
| Non-secure EL1&0 stage 1 | Non-secure EL1 | TCR_EL1, TTBR0_EL1, TTBR1_EL1 |

The following subsections give more information about controlling address translation:

- [System registers relevant to MMU operation.](#)
- [Address size configuration on page D4-1731.](#)
- [Atomicity of register changes on changing virtual machine on page D4-1735.](#)
- [Use of out-of-context translation regimes on page D4-1735.](#)

System registers relevant to MMU operation

In AArch64 state, System registers have a suffix, that indicates the lowest Exception level from which they can be accessed. In some general descriptions of MMU control and address translation, this chapter uses a *Common abbreviation on page D4-1731* for each of the System registers that affects MMU operation, as [Table D4-3 on page D4-1731](#) shows. The common abbreviation is used when describing features that apply to multiple translation regimes or stages.

Note

The only translation regime that supports a stage 2 translation is the Non-secure EL1&0 translation regime.

Table D4-3 Abbreviations for System registers used in this chapter

| Common abbreviation | Translation stage | Exception level | | |
|---------------------|-------------------|----------------------|-----------|-----------|
| | | EL1 | EL2 | EL3 |
| HCR | - | - | HCR_EL2 | - |
| SCTLR | - | SCTLR_EL1 | SCTLR_EL2 | SCTLR_EL3 |
| TCR | Stage 1 | TCR_EL1 | TCR_EL2 | TCR_EL3 |
| | Stage 2 | - | VTCR_EL2 | - |
| TTBR | Stage 1 | TTBR0_EL1, TTBR1_EL1 | TTBR0_EL2 | TTBR0_EL3 |
| | Stage 2 | - | VTTBR_EL2 | - |

Address size configuration

The following subsections specify the configuration of the PA size and of the input and output address sizes for each of the stages of address translation:

- [Physical address size.](#)
- [Output address size on page D4-1732.](#)
- [Input address size on page D4-1733.](#)
- [Supported IPA size on page D4-1734.](#)

Physical address size

The `ID_AA64MMFR0_EL1.PARange` field indicates the implemented PA size, as [Table D4-4](#) shows.

Table D4-4 Physical address size implementation options

| <code>ID_AA64MMFR0_EL1.PARange</code> | Total PA size | PA address size |
|---------------------------------------|---------------|-------------------|
| 0000 | 4 GB | 32 bits, PA[31:0] |
| 0001 | 64 GB | 36 bits, PA[35:0] |
| 0010 | 1 TB | 40 bits, PA[39:0] |
| 0011 | 4 TB | 42 bits, PA[41:0] |
| 0100 | 16 TB | 44 bits, PA[43:0] |
| 0101 | 256 TB | 48 bits, PA[47:0] |

All other PARange values are reserved.

Output address size

For each enabled stage of address translation, **TCR.{I}PS** must be programmed to maximum output address size for that stage of translation, using the encodings as shown in [Table D4-5](#).

Table D4-5 Output address size implementation options

| TCR.{I}PS | Total output size | Output address size |
|------------------|--------------------------|-----------------------------------|
| 000 | 4 GB | 32 bits, PA[31:0] |
| 001 | 64 GB | 36 bits, PA[35:0] |
| 010 | 1 TB | 40 bits, PA[39:0] |
| 011 | 4 TB | 42 bits, PA[41:0] |
| 100 | 16 TB | 44 bits, PA[43:0] |
| 101 | 256 TB | 48 bits, PA[47:0] |

Note

- This field is called **IPS** in the [TCR_EL1](#), and **PS** in the other **TCRs**.
- The **{I}PS** fields are 3-bit fields, corresponding to the least-significant **PARange** bits shown in [Table D4-4](#) on page D4-1731.

If **{I}PS** is programmed to a value larger than the implemented **PA** size, then the **PE** behaves as if programmed with the implemented **PA** size, but software must not rely on this behavior. That is, the output address size is never larger than the implemented **PA** size. [Table D4-4](#) on page D4-1731 shows the implemented **PA** size.

The **PE** checks that the **TTBR**, translation table entries, and the output address for the stage of address translation have the address bits above the output address size set to zero. If this is not the case, an Address size fault is generated for the level and stage of translation that caused the fault. An Address size fault from the **TTBR** is always reported as a level 0 fault.

If stage 1 translation is disabled and the input address is larger than the implemented **PA** size, then a stage 1 level 0 Address size fault is generated.

Note

These faults are reported as level 0 faults even if they occur in a translation stage that does not perform level 0 lookups.

When using two stages of translation:

- If stage 2 translation is disabled and the output address from the stage 1 translation is larger than the implemented **PA** size, then a stage 1 Address size fault is generated for the level of the stage 1 translation that generated the output address.
- If stage 2 translation is enabled and the output address from the stage 1 translation does not generate a stage 1 Address Size fault, but is larger than the input address size specified for the stage 2 translation, then a stage 2 Translation fault is generated.

Input address size

For each enabled stage of address translation, the **TCR.TxSZ** fields specify the input address size:

For a stage of translation that supports two VA ranges

The **TCR** has two **TxSZ** fields, corresponding to the two **VA** ranges:

- **TCR.T0SZ** specifies the size for the lower **VA** range, translated using **TTBR0**.
- **TCR.T1SZ** specifies the size for the upper **VA** range, translated using **TTBR1**.

For a stage of translation that supports a single input address (IA) range

The **TCR** has a single **T0SZ** field, and IAs are translated using **TTBR0**.

Attempting to translate an address that is larger than the configured input address size generates a Translation fault. This means:

- For a **TCR** with a single **T0SZ** field, [Figure D4-2](#) shows the input address map:

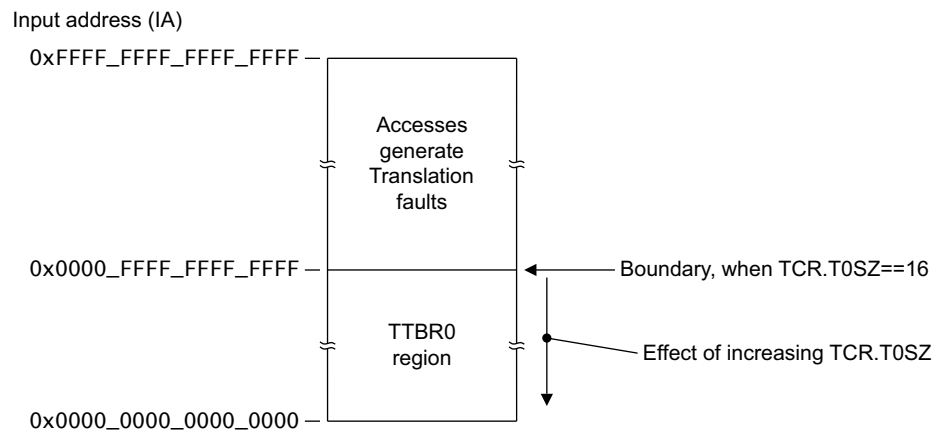

Figure D4-2 AArch64 input address map when using a single **TTBR**

- For a **TCR** with two **TxSZ** fields, the input address is always a **VA**, and [Selection between TTBR0 and TTBR1 when two VA ranges are supported on page D4-1759](#) describes the **VA** address map.

For the Non-secure EL1&0 translation regime, when both stages of translation are enabled, if the output address from the stage 1 translation does not generate a stage 1 address size fault, and is larger than the input address specified by **VTCR_EL2.T0SZ**, then the input address size check for the stage 2 translation generates a Translation fault.

Although software can configure the input address size to be smaller than 48 bits, all implemented AArch64 **TTBRs** must support address sizes of up to 48 bits.

[Overview of the VMSAv8-64 address translation stages on page D4-1745](#) gives more information about the relationship between the required input address size, the value of **TxSZ**, and the required initial lookup level, and how these are affected by the translation granule size. However:

For all translation stages

The maximum **TxSZ** value is 39. If **TxSZ** is programmed to a value larger than 39 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field is programmed to 39 for all purposes other than reading back the value of the field.
- Any use of the **TxSZ** value generates a Level 0 Translation fault for the stage of translation at which **TxSZ** is used.

For a stage 1 translation

The minimum TxSZ value is 16. If TxSZ is programmed to a value smaller than 16 then it is IMPLEMENTATION DEFINED whether:

- The implementation behaves as if the field were programmed to 16 for all purposes other than reading back the value of the field.
- Any use of the TxSZ value generates a stage 1 Level 0 Translation fault.

For a stage 2 translation

Supported IPA size defines the effective minimum value of T0SZ, that depends on the supported PA size, and also describes the possible effects of programming T0SZ to a value that is smaller than this effective minimum value.

Supported IPA size

For the Non-secure EL1&0 translation regime, the maximum IPA size is the maximum input address size for the second stage of translation, that must be specified by VTCR_EL2.T0SZ, see *Input address size on page D4-1733*. This value is constrained by the implemented PA size that is specified by ID_AA64MMFR0_EL1.PARange, see *Physical address size on page D4-1731*. This implemented PA size also constrains the maximum value of VTCR_EL2.SL0, that specifies the level of the initial lookup. SL0 also depends on the translation granule, as described in *Overview of the VMSAv8-64 address translation stages on page D4-1745*.

Table D4-6 PA size implications for the VTCR_EL2.{T0SZ, SL0} fields

| Supported PA size | Effective minimum T0SZ value | Maximum SL0 value | | |
|-------------------|--|-------------------|--------------|--------------|
| | | 4KB granule | 16KB granule | 64KB granule |
| 32 bits | 32 if EL1 is using AArch64 24 if EL1 is using AArch32 | 1 | 1 | 1 |
| 36 bits | 28 if EL1 is using AArch64 24 if EL1 is using AArch32 | 1 | 1 | 1 |
| 40 bits | 24 | 1 | 1 | 1 |
| 42 bits | 22 | 1 | 2 | 1 |
| 44 bits | 20 | 2 | 2 | 2 |
| 48 bits | 16 | 2 | 2 | 2 |

If VTCR_EL2.SL0 is programmed to a value larger than the maximum value shown in Table D4-6, or is programmed to a reserved value, then any memory access that uses the second stage of translation generates a stage 2 level 0 Translation fault.

If VTCR_EL2.T0SZ is programmed to a value smaller than the effective minimum value shown in Table D4-6 then the implementation consistently does one of the following:

- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than reading back the value of the field.
- Treat the VTCR_EL2.T0SZ field as being programmed to the effective minimum value for all purposes other than:
 - Reading back the value of the field.
 - Checking whether the value of VTCR_EL2.T0SZ is consistent with the value of VTCR_EL2.SL0.
- Generate a stage 2 level 0 Translation fault on any memory access that uses the second stage of translation.

Note

Programming [VTCR_EL2.T0SZ](#) to a value smaller than the effective minimum value shown in [Table D4-6 on page D4-1734](#) can never provide support for a larger address range than the range given by the effective minimum value, because the stage 1 output address will give an Address size fault if it is larger than either:

- The [PA](#) size, for a VMSAv8-64 stage 1 translation.
 - 40 bits, for a VMSAv8-32 stage 1 translation.
-

Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure EL1 or EL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure EL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
 - [MAIR_EL1](#) and [AMAIR_EL1](#).
 - [TTBR0_EL1](#), [TTBR1_EL1](#), [TCR_EL1](#), and [CONTEXTIDR_EL1](#).
 - [SCTLR_EL1](#).
- The registers associated with the stage 2 translations:
 - [VTTBR_EL2](#) and [VTCR_EL2](#).
 - [SCTLR_EL2](#).

Note

Only some bits of [SCTLR_EL1](#) affect the stage 1 translation, and only some bits of [SCTLR_EL2](#) affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure EL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3, EL2, or Secure EL1, the PE must not use the registers associated with the Non-secure EL1&0 translation regime for speculative memory accesses.
- When executing at EL3 or Secure EL1, the PE must not use the registers associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure EL1 translation regime for speculative memory accesses.

When entering an Exception level, on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an Exception level lower than the Exception level that has been entered will be observed by any observers, to the extent that those accesses are required to be observed as determined by the shareability and cacheability of those translation table entries.

Note

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.
- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

D4.2.3 Memory translation granule size

The memory translation granule size defines both:

- The maximum size of a single translation table.
- The memory *page* size. That is, the granularity of a translation table lookup.

VMSAv8-64 supports translation granule sizes of 4KB, 16KB, and 64KB. Support for each granule size is optional, and is indicated as shown in [Table D4-7](#):

Table D4-7 Identifying supported granule sizes

| Granule size | Support indicated by: | | Values |
|--------------|--------------------------|--------|----------------------------------|
| | Field | | |
| 4KB | ID_AA64MMFR0_EL1.TGRAN4 | 0b0000 | 4KB granule size supported. |
| | | 0b1111 | 4KB granule size not supported. |
| 16KB | ID_AA64MMFR0_EL1.TGRAN16 | 0b0000 | 16KB granule size not supported. |
| | | 0b0001 | 16KB granule size supported. |
| 64KB | ID_AA64MMFR0_EL1.TGRAN64 | 0b0000 | 64KB granule size supported. |
| | | 0b1111 | 64KB granule size not supported. |

In VMSAv8-64, each address translation stage is configured, independently, to use one of the supported granule sizes.

Note

- Using a larger granule size can reduce the maximum required number of levels of address lookup because:
 - The increased translation table size means the translation table holds more entries. This means a single lookup can resolve more bits of the input address.
 - The increased page size means more of the least-significant address bits are required to address a page. These address bits are flat mapped from the input address to the output address, and therefore do not require translation.
- ARM recommends that memory-mapped peripherals are separated by an integer multiple of the largest granule size supported by the operating system or hypervisor, to allow each peripheral to be managed independently.

Table D4-8 summarizes the effects of the different granule sizes.

Table D4-8 Effect of granule size on a stage of address translation

| Property | 4KB granule | 16KB granule | 64KB granule | Notes |
|--|-----------------------|-----------------------|-----------------------|--|
| Maximum number of entries in a translation table | 512 | 2048 (2K) | 8192 (8K) | - |
| Address bits resolved in one level of lookup | 9 | 11 | 13 | $2^9=512$, $2^{11}=2K$, $2^{13}=8K$ |
| Page size | 4KB | 16KB | 64KB | - |
| Page address range | VA[11:0]= PA[11:0] | VA[13:0]= PA[13:0] | VA[15:0]= PA[15:0] | $2^{12}=4K$, $2^{14}=16K$, $2^{16}=64K$ |

How the granule size affects the address translation process

As Table D4-8 shows, the translation granule determines the number of address bits:

- Required to address a memory page.
- That can be resolved in a single translation table lookup.

This means the translation granule determines how the *input address* (IA) is resolved to an *output address* (OA) by the translation process.

Because a single translation table lookup can resolve only a limited number of address bits, the IA to OA resolution requires multiple *levels* of lookup.

Considering the resolution of the maximum IA range of 48 bits, with a translation granule size of 2^n bytes:

- The least-significant n bits of the IA address the memory page. This means $OA[(n-1):0]=IA[(n-1):0]$.
- The remaining $(48-n)$ bits of the IA, $IA[47:n]$, must be resolved by the address translation.
- A translation table descriptor is 8 bytes. Therefore:
 - A complete translation table holds $2^{(n-3)}$ descriptors.
 - A single level of translation can resolve a maximum of $(n-3)$ bits of address.

Consider the translation process, working back from the final level of lookup, that resolves the least significant of the address bits that require translation. Because the translation needs to resolve $IA[47:n]$ and a level of lookup can resolve $(n-3)$ bits of address:

- The final level of lookup resolves $IA[(2n-4):n]$.
- The previous level of lookup resolves $IA[(3n-7):(2n-3)]$.

However, the level of lookup that resolves the most significant bits of the IA might not require a full-sized translation table. Therefore, in general, for a 48-bit IA the address bits resolved in a level of lookup are:

$IA[\text{Min}(47, ((x-3)(n-3)+2n-4)): (n+(x-3)(n-3))]$, where:

Min(a, b) Is a function that returns the minimum of a and b .

x Indicates the level of lookup. This is defined so that the level that resolves the least significant bit of the translated IA bits is level 3.

The following diagrams show this model, for each of the permitted granule sizes.

Figure D4-3 on page D4-1738 shows how a 48-bit IA is resolved when using the 4KB translation granule.

Using the 4KB translation granule

Figure D4-3 How a 48-bit IA is resolved when using the 4KB translation granule

Figure D4-4 shows how a 48-bit IA is resolved when using the 16KB translation granule.

Using the 16KB translation granule

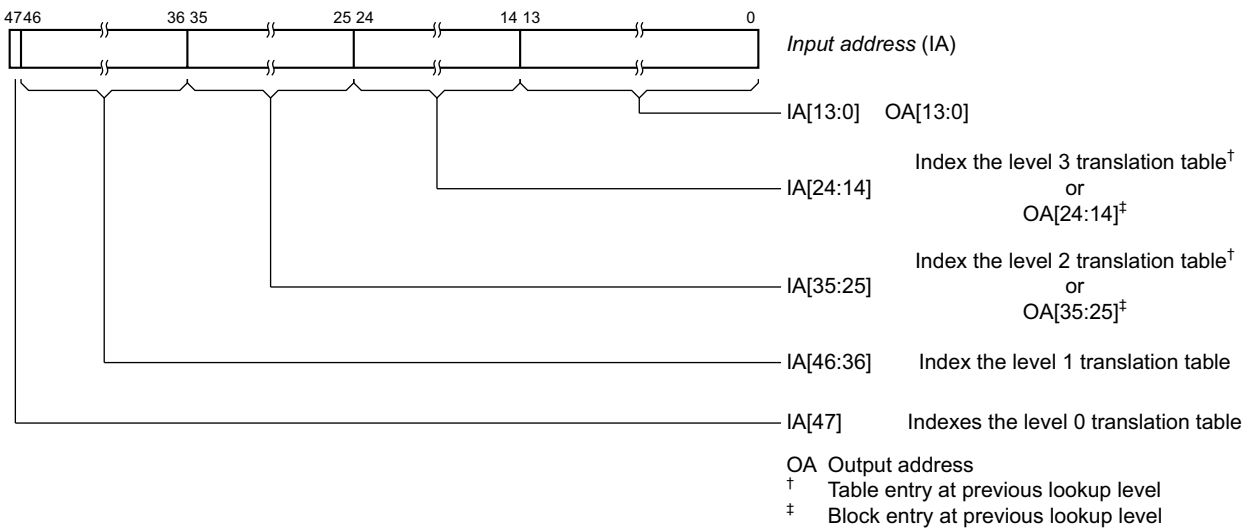

Figure D4-4 How a 48-bit IA is resolved when using the 16KB translation granule

Figure D4-5 shows how a 48-bit IA is resolved when using the 64KB translation granule.

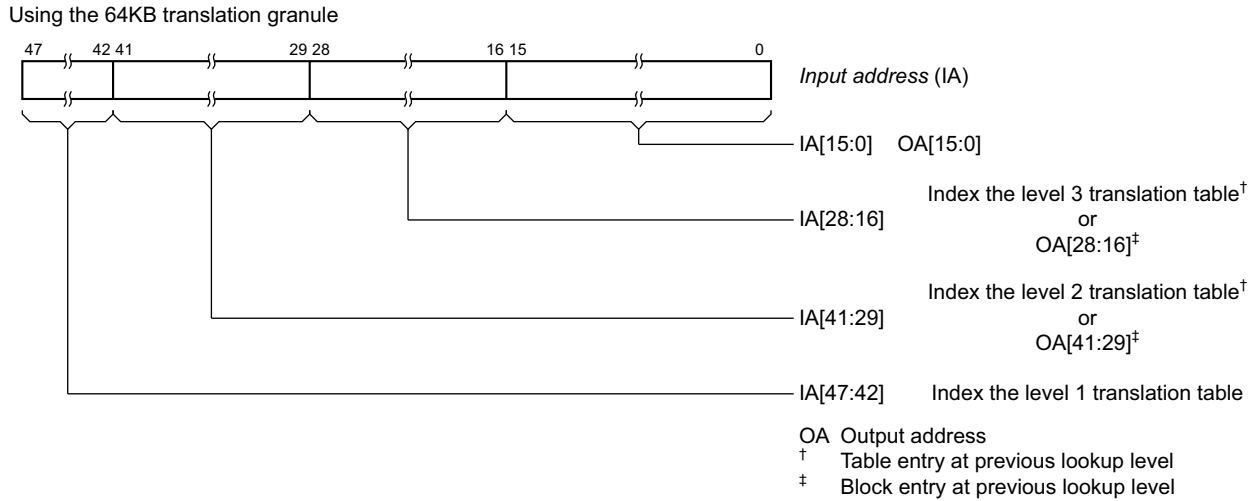

Figure D4-5 How a 48-bit IA is resolved when using the 64KB translation granule

Later sections of this chapter give more information about the translation process, and explain the terminology used in these figures.

Effect of granule size on translation table addressing and indexing

Table D4-9 shows the effect of the translation granule size on the addressing and indexing of the TTBR, and on the input address range that must be resolved.

Table D4-9 The effect of translation granule size on the translation tables

| Granule size | Translation table | | Translation resolves ^a | Notes |
|--------------|-------------------|-------------------------|-----------------------------------|---|
| | Addressed by | Indexed by ^b | | |
| 4KB | TTBR[47:12] | IA[(x + 8):x] | IA[47:12] | One level of lookup resolves up to ^c 9 bits of IA |
| 16KB | TTBR[47:14] | IA[(x + 10):x] | IA[47:14] | One level of lookup resolves up to ^c 11 bits of IA |
| 64KB | TTBR[47:16] | IA[(x + 12):x] | IA[47:16] | One level of lookup resolves up to ^c 13 bits of IA |

- When translating a maximum-sized input address of 48 bits, and accessing a page of memory.
- Where the value of x depends on the lookup level, see Table D4-10.
- Depending on the IA size, the initial lookup might resolve fewer bits of the IA.

Table D4-10 shows the IA bits resolved at each level of lookup, and how these correspond to the possible values of x in Table D4-9.

Table D4-10 IA bits resolved at different levels of lookup

| Lookup level | 4KB granule size | 16KB granule size | 64KB granule size |
|--------------|---------------------|--------------------------------|-----------------------------------|
| Zero | IA[47:39], $x = 39$ | IA[47 ^a], $x = 47$ | - ^b |
| First | IA[38:30], $x = 30$ | IA[46:36], $x = 36$ | IA[47 ^a :42], $x = 42$ |

Table D4-10 IA bits resolved at different levels of lookup (continued)

| Lookup level | 4KB granule size | 16KB granule size | 64KB granule size |
|--------------|---------------------|---------------------|---------------------|
| Second | IA[29:21], $x = 21$ | IA[35:25], $x = 25$ | IA[41:29], $x = 29$ |
| Third | IA[20:12], $x = 12$ | IA[24:14], $x = 14$ | IA[28:16], $x = 16$ |

- a. Smaller value than indicated in [Table D4-9 on page D4-1739](#), as explained in this section.
- b. Level 0 lookup not possible with 64KB granule size

[Table D4-9 on page D4-1739](#) refers to accessing a complete translation table, of 4KB, 16KB, or 64KB. However, the ARMv8 translation system supports the following possible variations from the information in [Table D4-9 on page D4-1739](#):

Reduced IA width

Depending on the configuration and implementation choices, the required input address width for the initial level of lookup might be smaller than the number of address bits that can be resolved at that level. This means that, for this initial level of lookup:

- The translation table size is reduced. For each 1 bit reduction in the input address size the size of the translation table is halved.

Note

- This has no effect on the translation table size for subsequent levels of lookup, for which the lookups always use full-sized translation tables.
- For a stage 2 translation, it might be possible to start the translation at a lower level, see [Concatenated translation tables on page D4-1741](#).

- More low-order **TTBR** bits are needed to hold the translation table base address.

[Example D4-1](#) shows how this applies to translating a 35-bit input address range using the 4KB granule.

Example D4-1 Effect of an IA width of 35 bits when using the 4KB granule size

With a 4KB granule size, a single level of lookup can resolve up to 9 bits of IA. If an implementation has a 35-bit input address range, IA[34:0], [Table D4-10 on page D4-1739](#) shows that lookup must start at level 1, and that the initial lookup must resolve IA[34:30], meaning it resolves 5 bits of address: This 4-bit reduction in the required resolution means:

- The translation table size is divided by 2^4 , giving a size of 256B.
- The **TTBR** requires 4 more bits for the translation table base address, which becomes **TTBR**[47:8].

When using the 64KB translation granule to translate the maximum IA size of 48 bits, [Table D4-10 on page D4-1739](#) shows that a level 1 lookup must resolve only IA[47:42]. This is 6 bits of address, compared to the 13 bits that can be resolved at a single level of lookup. This 7-bit reduction in the required resolution means:

- The translation table size is divided by 2^7 , giving a size of 512B.
- The **TTBR** requires 7 more bits for the translation table base address, which becomes **TTBR**[47:9].

Concatenated translation tables

For stage 2 address translations, for the initial lookup, up to 16 translation tables can be concatenated. This means additional IA bits can be resolved at that lookup level. The block of concatenated translation tables must be aligned to the size of the block of translation tables.

This means that each additional IA bit resolved:

- Doubles the number of translation tables required. Resolving an additional n bits requires 2^n concatenated translation tables at the initial lookup level.
- Reduces by 1 bit the width of the translation table base address held in the **TTBR**.

This means that, for the initial lookup of a stage 2 translation table, the IA ranges shown in [Table D4-10 on page D4-1739](#) can be extended by up to 4 bits. [Example D4-2](#) shows how concatenation can be used to resolve a 40-bit IA when using the 4KB translation granule.

Example D4-2 Concatenating translation tables to resolve a 40-bit IA range, with the 4K granule

[Table D4-10 on page D4-1739](#) shows that, when using the 4KB translation granule, a level 1 lookup can resolve a 39-bit IA, with the first lookup resolving IA[38:30]. For a stage 2 translation, to extend the IA width to 40 bits and resolve IA[39:30] with the first lookup:

- Two translation tables are concatenated, giving a total size of 8KB.
- The **TTBR** requires 1 fewer bit for the translation table base address, which becomes **TTBR**[47:13].

For more information, see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-1761](#).

In all cases, the translation table, or block of concatenated translation tables, must be aligned to the actual size of the table or block of concatenated tables.

The translation table base address held in the **TTBR** is defined in the OA map for that stage of address translation. The information given in this section assumes this stage of translation has an OA size of 48 bits, meaning the translation table base address is:

- **TTBR**[47:12] if using the 4KB translation granule.
- **TTBR**[47:14] if using the 16KB translation granule.
- **TTBR**[47:16] if using the 64KB translation granule.

If the OA address is smaller than 48 bits then the upper bits of this field must be written as zero. For example, for a 40-bit OA range:

- If using the 4KB translation granule:
 - **TTBR**[47:40] must be set to zero.
 - **TTBR**[39:12] holds the translation table base address.
- If using the 16KB translation granule:
 - **TTBR**[47:40] must be set to zero.
 - **TTBR**[39:14] holds the translation table base address.
- If using the 64KB translation granule:
 - **TTBR**[47:40] must be set to zero.
 - **TTBR**[39:16] holds the translation table base address.

In all cases, if **TTBR**[47:40] is not zero, any attempt to access the translation table generates an Address size fault.

D4.2.4 Translation tables and the translation process

The following subsections describe general properties of the translation tables and translation table walks, that are largely independent of the translation table format:

- [Translation table walks](#).
- [Ordering of memory accesses from translation table walks](#) on page D4-1744.
- [Security state of translation table lookups](#) on page D4-1744.
- [Control of translation table walks](#) on page D4-1744.

See also [Selection between TTBR0 and TTBR1 when two VA ranges are supported](#) on page D4-1759.

Translation table walks

A *translation table walk* comprises one or more *translation table lookups*. The translation table walk is the set of lookups that are required to translate the VA to the PA. For the Non-secure EL1&0 translation regime, this set includes lookups for both the stage 1 translation and the stage 2 translation, but *translation table walk* can also be used to refer to either:

- The set of lookups required for the stage 1 translation, that translates the VA to the IPA. This is the *stage 1 translation table walk*.
- The set of lookups required for the stage 2 translation, that translates the IPA to the PA. This is the *stage 2 translation table walk*.

The information returned by a successful translation table walk is:

- The required PA. If the access is from Secure state this includes identifying whether the access is to the Secure PA space or the Non-secure PA space, see [Security state of translation table lookups](#) on page D4-1744.
- The memory attributes for the target memory region, as described in [Memory types and attributes](#) on page B2-94. For more information about how the translation table descriptors specify these attributes see [Memory region attributes](#) on page D4-1792.
- The access permissions for the target memory regions. For more information about how the translation table descriptors specify these permissions see [Memory access control](#) on page D4-1783.

The translation table walk starts with a read of the translation table for the initial lookup. The TTBR for the stage of translation holds the base address of this table. Each translation table lookup returns a descriptor, that indicates one of the following:

- The entry is the final entry of the walk. In this case, the entry contains the OA, and the permissions and attributes for the access.
- An additional level of lookup is required. In this case, the entry contains the translation table base address for that lookup. In addition:
 - The descriptor provides hierarchical attributes that are applied to the final translation, see [Hierarchical control of Secure or Non-secure memory accesses](#) on page D4-1782 and [Hierarchical control of data access permissions](#) on page D4-1785.
 - If the translation is in a Secure translation regime, the descriptor indicates whether that base address is in the Secure or Non-secure address space, unless a hierarchical control at a previous level of lookup has indicated that it must be in the Non-secure address space.
- The descriptor is invalid. In this case, the memory access generates a Translation fault.

Figure D4-6 gives a generalized view of a single stage of address translation, where three levels of lookup are required.

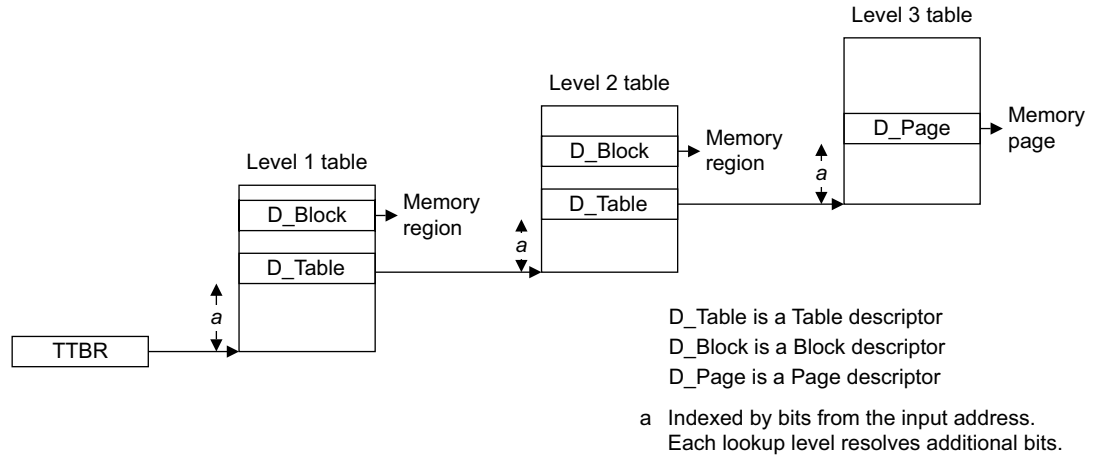

Figure D4-6 Generalized view of a stage of address translation

A translation table lookup from VMSAv8-64 performs a single-copy atomic 64-bit access to the translation table entry. This means the translation table entry is treated as a 64-bit object for the purpose of endianness. `SCTLR.EE` determines the endianness of the translation table lookups.

———— **Note** ————

Dynamically changing translation table endianness

Because any change to an `SCTLR.EE`, bit requires synchronization before it is visible to subsequent operations, ARM strongly recommends that any EE bit is changed only when either:

- Executing at an Exception level that does not use the translation tables affected by the EE bit being changed.
- Executing with address translation disabled for any stage of translation affected by the EE bit being changed.

Address translation stages are disabled by setting an `SCTLR.M` bit or the `HCR_EL2.VM` bit to 0. See the appropriate register description for more information.

The appropriate `TTBR` holds the output address of the base of the translation table used for the initial lookup, and:

- For all address translation stages other than Non-secure EL1&0 stage 1 translations, the output address held in the `TTBR`, and any translation table base address returned by a translation table descriptor, is the `PA` of the base of the translation table.
- For Non-secure EL1&0 stage 1 translations, the output address held in the `TTBR`, and any translation table base address returned by a translation table descriptor, is the `IPA` of the base of the translation table. This means that if stage 2 address translation is enabled, each of these OAs is subject to second stage translation.

———— **Note** ————

TLB caching can be used to minimise the number of translation table lookups that must be performed. For the Non-secure EL1&0 translation regime, because each stage 1 OA generated during a translation table walk is subject to a stage 2 translation, if the caching of translation table entries is ineffective, a `VA` to `PA` address translation with two stages of translation can give rise to multiple translation table lookups. The number of lookups required is given by the following equation:

$$(S1+1)*(S2+1) - 1$$

Where, for this translation regime, S1 is the number of levels of lookup required for a stage 1 translation, and S2 is the number of levels of lookup required for a stage 2 translation.

The **TTBR** also determines the memory cacheability and shareability attributes that apply, for the corresponding stage of translation, to all translation table lookups generated by that stage of translation.

The Normal memory type is the memory type defined for a translation table lookup for a stage of translation.

———— **Note** —————

- In a two stage translation regime, a translation table lookup from stage 1, that has the Normal memory type defined at stage 1 by this rule, can still be given the Device memory type as part of the stage 2 translation of that address. ARM strongly recommends against such a remapping of the memory type, and the architecture includes a trap of this behavior to EL2. For more information, see [Stage 2 fault on a stage 1 translation table walk on page D4-1806](#).
- The rules about mismatched attributes given in [Mismatched memory attributes on page B2-105](#) apply to the relationship between translation table walks and explicit memory accesses to the translation tables in the same way that they apply to the relationship between different explicit memory accesses to the same location. For this reason, ARM strongly recommends that the attributes that the **TCR** applies to the translation tables are the same as the attributes that are applied for explicit accesses to the memory that holds the translation tables.

For more information see [Overview of the VMSAv8-64 address translation stages on page D4-1745](#).

See also [Selection between TTBR0 and TTBR1 when two VA ranges are supported on page D4-1759](#).

Ordering of memory accesses from translation table walks

A translation table walk is considered to be a separate observer, and:

- A write to the translation tables can be observed by that separate observer at any time after the execution of the instruction that performed that write, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the instruction that performed that write to the translation tables.
- Any writes to the translation tables are not seen by any explicit memory access generated by a load or store that occurs in program order before the instruction that performs the write to the translation tables.

Security state of translation table lookups

For a Non-secure translation regime, all translation table lookups are performed to Non-secure output addresses.

For a Secure translation regimes, the initial translation table lookup is performed to a Secure output address.

If the translation table descriptor returned as a result of that initial lookup points to a second translation table, then the NSTable bit in that descriptor determines whether that translation table lookup is made to Secure or to Non-secure output addresses.

This applies for all subsequent translation table lookups as part of that translation table walk, with the additional rule that any translation table descriptor that is returned from Non-secure memory is treated as if the NSTable bit in that descriptor indicates that the subsequent translation table lookup is to Non-secure memory.

Control of translation table walks

For a stage 1 translation that supports two VA ranges the **TCR_ELx**.{EPD0, EPD1} bits determine whether the translation tables for the stage are valid. EPD0 indicates whether the table that **TTBR0_ELx** points to is valid, and EPD1 indicates whether the table that **TTBR1_ELx** points to is valid. The effect of these bits is:

EPD_n == 0 The translation table is valid, and can be used for a translation table lookup.

EPD_n == 1 If a TLB miss occurs based on **TTBR_n**, a Translation fault is returned, and no translation table walk is performed. The fault is reported as a level 0 fault.

D4.2.5 Overview of the VMsAv8-64 address translation stages

As shown in *Memory translation granule size* on page D4-1736, the granule size determines significant aspects of the address translation process. *Effect of granule size on translation table addressing and indexing* on page D4-1739 shows, for each granule size:

- How the required input address range determines the required initial lookup levels.
- For stage 2 translations, the possible effect described in *Concatenated translation tables* on page D4-1741.
- The **TTBR** addressing and indexing for the initial lookup.

The following subsections summarize the multiple levels of lookup that can be required for a single stage of address translation that might require the maximum number of lookups:

- *Overview of VMsAv8-64 address translation using the 4KB translation granule.*
- *Overview of VMsAv8-64 address translation using the 16KB translation granule* on page D4-1749.
- *Overview of VMsAv8-64 address translation using the 64KB translation granule* on page D4-1753.

Overview of VMsAv8-64 address translation using the 4KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 4KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding **TCR.TnSZ** field. When using the 4KB translation granule, [Table D4-11](#) shows this requirement.

Table D4-11 TCR.TnSZ values and IA ranges, 4K granule with no concatenation of tables

| Initial lookup level | TnSZ values for and input address ranges ^a for starting at this level | | | |
|----------------------|--|-------------------|---------------------|-------------------|
| | TnSZ _{min} | IA _{max} | TnSZ _{max} | IA _{min} |
| 0 | 16 | IA[47:12] | 24 | IA[39:12] |
| 1 | 25 | IA[38:12] | 33 | IA[30:12] |
| 2 | 34 | IA[29:12] | 39 | IA[24:12] |

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

Figure D4-7 shows the stage 1 address translation, for an address translation using the 4KB granule with an input address size greater than 39 bits.

Figure D4-7 General view of VMSAv8-64 stage 1 address translation, 4KB granule

Overview of stage 2 translations, 4KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-1761](#).

When using the 4KB translation granule, [Table D4-12](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-12 VTCR_EL2.T0SZ values and IA ranges, 4K granule with possible concatenation of translation tables

| Tables ^a | 1 | 2 | | 4 | | 8 | | 16 | | |
|----------------------|--|---------------------|------|-----------|------|-----------|------|-----------|------|-----------|
| Initial lookup level | T0SZ values and input address ranges ^b for starting at this level | | | | | | | | | |
| | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA |
| 0 | 16-24 | IA[47:12]-IA[39:12] | - | - | - | - | - | - | - | - |
| 1 | 25-33 | IA[38:12]-IA[30:12] | 24 | IA[39:12] | 23 | IA[40:12] | 22 | IA[41:12] | 21 | IA[42:12] |
| 2 | 34-39 | IA[29:12]-IA[24:12] | 33 | IA[30:12] | 32 | IA[31:12] | 31 | IA[32:12] | 30 | IA[33:12] |

a. Number of concatenated translation tables at the initial lookup level. 1 table corresponds to no concatenation, also shown in [Table D4-11 on page D4-1745](#).
b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the Note that follows.

Note

- When using the 4KB translation granule, the initial lookup cannot be at level 3.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 4KB translation granule, tables cannot be concatenated at level 0.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 4KB translation granule, IA[11:0] = OA[11:0] for all translations.

In addition, `VTCCR_EL2.SL0` indicates the required initial lookup level, as [Table D4-13](#) shows.

Table D4-13 `VTCCR_EL2.SL0` values, 4KB granule

| Initial lookup level | <code>VTCCR_EL2.SL0</code> |
|----------------------|----------------------------|
| 0 | 0b10 |
| 1 | 0b01 |
| 2 | 0b00 |

The `VTCCR_EL2.SL0` value 0b11 is reserved.

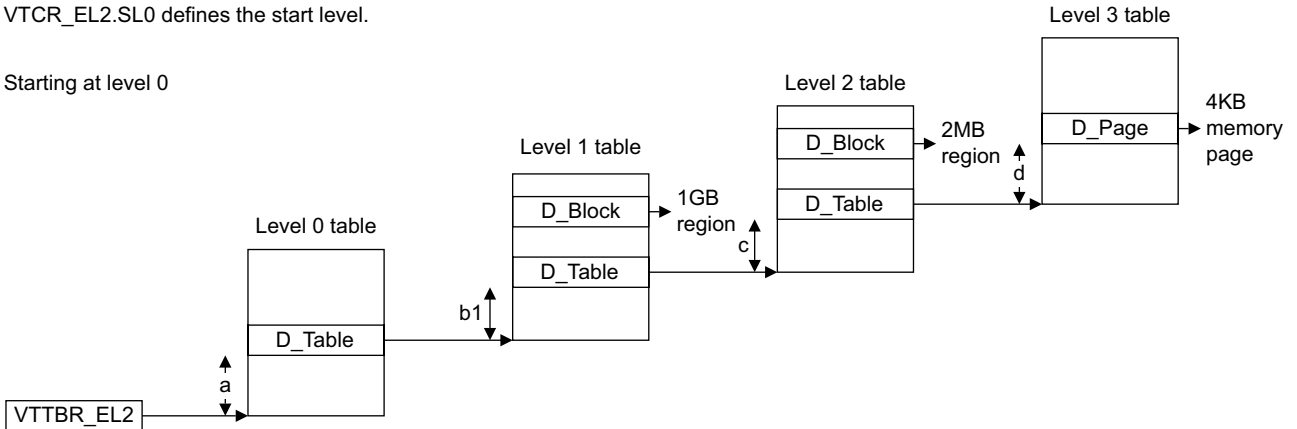

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted `VTCCR_EL2.{T0SZ, SL0}` values. [Table D4-12 on page D4-1746](#) shows the permitted T0SZ values for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or `VTCCR_EL2.SL0` is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

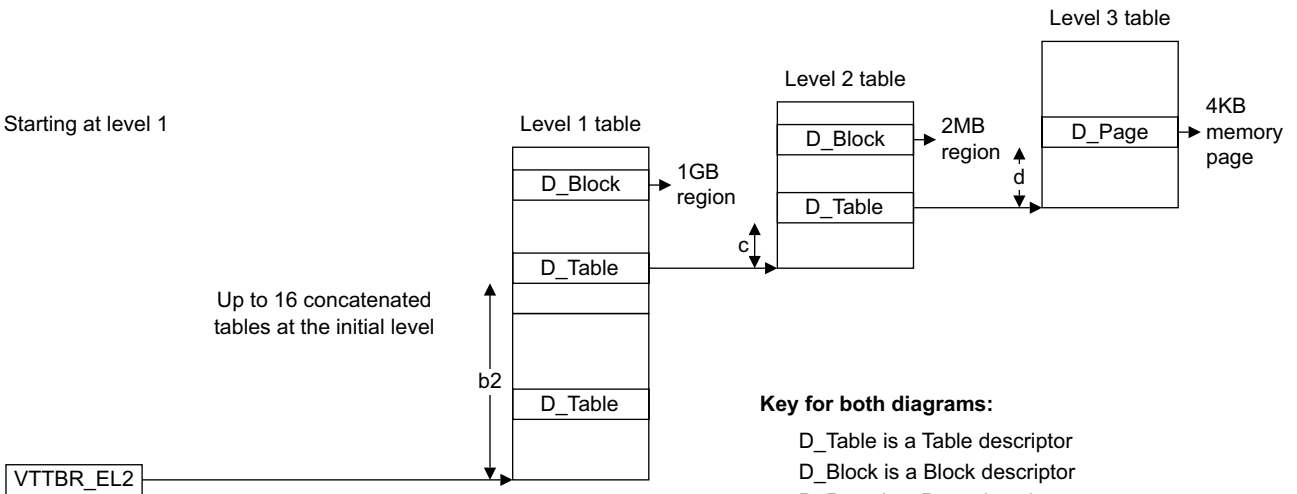

Figure D4-8 shows the stage 2 address translation, for an input address size of between 40 and 43 bits. For an input address size in this range, the lookup can start at either level 0 or level 1.

VTCR_EL2.SL0 defines the start level.

Starting at level 0

Starting at level 1

Key for both diagrams:

- D_Table is a Table descriptor
- D_Block is a Block descriptor
- D_Page is a Page descriptor
- a Indexed by IA[n:39], where IA width is (n+1) bits
- b1 Indexed by IA[38:30]
- b2 Indexed by IA[n:30], where IA width is (n+1) bits
- c Indexed by IA[29:21]
- d Indexed by IA[20:12]

Figure D4-8 General view of VMSAv8-64 stage 2 address translation, 4KB granule

Overview of VMSAv8-64 address translation using the 16KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 16KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR.TnSZ` field. When using the 16KB translation granule, Table D4-14 shows this requirement.

Table D4-14 `TCR.TnSZ` values and IA ranges, 16K granule with no concatenation of tables

| Initial lookup level | TnSZ values for and input address ranges ^a for starting at this level | | | |
|----------------------|--|-------------------|---------------------|-------------------|
| | TnSZ _{min} | IA _{max} | TnSZ _{max} | IA _{min} |
| 0 | 16 | IA[47:14] | - | - |
| 1 | 17 | IA[46:14] | 27 | IA[36:14] |
| 2 | 28 | IA[35:14] | 38 | IA[25:14] |
| 3 | 39 | IA[24:14] | - | - |

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

The configuration options for an initial lookup at level 1, level 2, or level 3 are also permitted for stage 2 translations, but stage 2 translation does not permit an initial lookup at level 0.

Note

- When using the 16KB translation granule, a maximum of 1 bit of IA is resolved by a level 0 lookup.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, `IA[13:0] = OA[13:0]` for all translations.

Figure D4-9 shows the stage 1 address translation, for an address translation using the 16KB granule with an input address size of 48 bits.

Figure D4-9 General view of VMSAv8-64 stage 1 address translation, 16KB granule

Overview of stage 2 translations, 16KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-1761](#).

When using the 16KB granule, for a stage 2 translation with an input address sized of 48 bits, the initial lookup must be at level 1, with two concatenated translation tables at this level.

When using the 16KB translation granule, [Table D4-15](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-15 VTCR_EL2.T0SZ values and IA ranges, 16K granule with possible concatenation of translation tables

| Tables ^a | 1 | | 2 | | 4 | | 8 | | 16 | |
|----------------------|--|---------------------|------|-----------|------|-----------|------|-----------|------|-----------|
| Initial lookup level | T0SZ values and input address ranges ^b for starting at this level | | | | | | | | | |
| | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA |
| 1 | 17-27 | IA[46:14]-IA[36:14] | 16 | IA[47:14] | - | - | - | - | - | - |
| 2 | 28-38 | IA[35:14]-IA[25:14] | 27 | IA[36:14] | 26 | IA[37:14] | 25 | IA[38:14] | 24 | IA[39:14] |
| 3 | 39 | IA[24:14] | 38 | IA[25:14] | 37 | IA[26:14] | 36 | IA[27:14] | 35 | IA[28:14] |

- a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, also shown in [Table D4-14 on page D4-1749](#).
- b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

Note

- When using the 16KB translation granule for a stage 2 translation, the initial lookup cannot be at level 0. When a 48-bit input address is required, translation must start with a level 1 lookup using two concatenated translation tables.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 16KB translation granule, IA[13:0] = OA[13:0] for all translations.

In addition, VTCR_EL2.SL0 indicates the required initial lookup level, as [Table D4-16](#) shows.

Table D4-16 VTCR_EL2.SL0 values, 16KB granule

| Initial lookup level | VTCR_EL2.SL0 |
|----------------------|--------------|
| 1 | 0b10 |
| 2 | 0b01 |
| 3 | 0b00 |

The VTCR_EL2.SL0 value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. [Table D4-15](#) shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

When stage 2 translation supports a 48-bit input address range, translation must start with a level 1 lookup using two concatenated translation tables. Figure D4-10 shows the translation for this case.

Figure D4-10 VMSAv8-64 stage 2 address translation, 16KB granule, 48 bit input address

However, for an input address size of between 37 and 40 bits, Table D4-15 on page D4-1750 shows that translation can start with either a level 1 lookup or a level 2 lookup, and Figure D4-11 shows these options.

VTCR_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

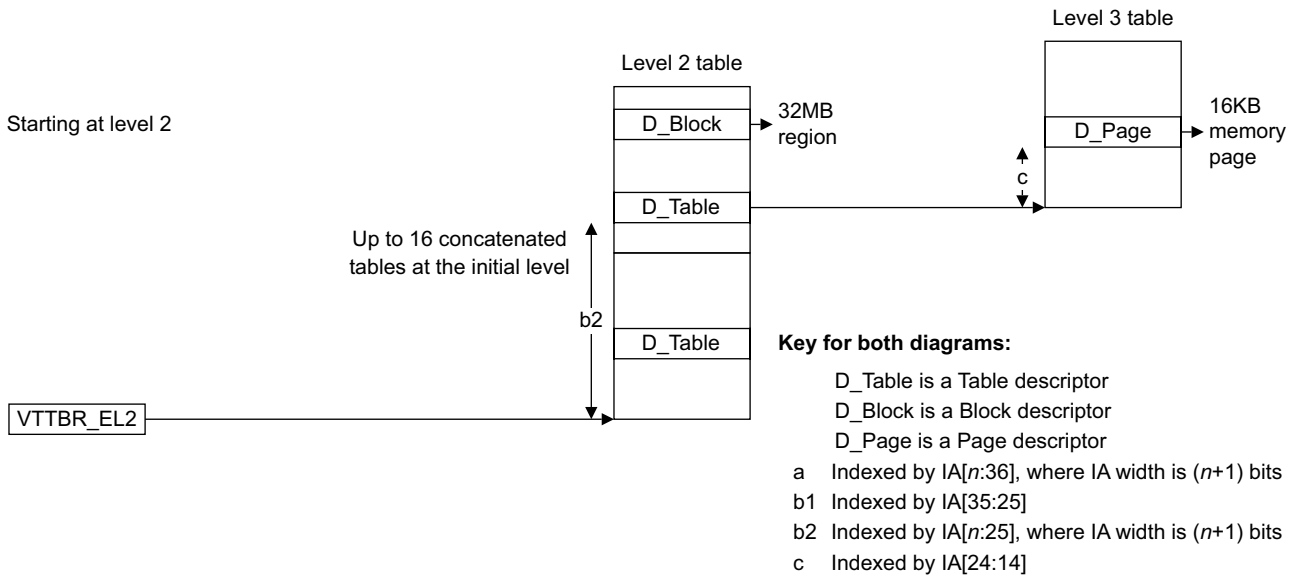

Figure D4-11 General view of VMSAv8-64 stage 2 address translation, 16KB granule

Overview of VMSAv8-64 address translation using the 64KB translation granule

The requirements for the level of the initial lookup are different for stage 1 and stage 2 translations.

Overview of stage 1 translations, 64KB granule

For a stage 1 translation, the required initial lookup level is determined only by the required input address range specified by the corresponding `TCR.TnSZ` field. When using the 64KB translation granule, Table D4-17 shows this requirement.

Table D4-17 `TCR.TnSZ` values and IA ranges, 64K granule with no concatenation of tables

| Lookup level | TnSZ values for and input address ranges ^a for starting at this level | | | |
|--------------|--|-------------------|---------------------|-------------------|
| | TnSZ _{min} | IA _{max} | TnSZ _{max} | IA _{min} |
| 1 | 16 | IA[47:16] | 21 | IA[42:16] |
| 2 | 22 | IA[41:16] | 34 | IA[29:16] |
| 3 | 35 | IA[28:16] | 39 | IA[24:16] |

a. The IAs show the address bits to be resolved when addressing a page of memory, see the *Note* that follows.

These configuration options are also permitted for stage 2 translations.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, `IA[15:0] = OA[15:0]` for all translations.

Figure D4-12 shows the stage 1 address translation, for an address translation using the 64KB granule with an input address size greater than 42 bits.

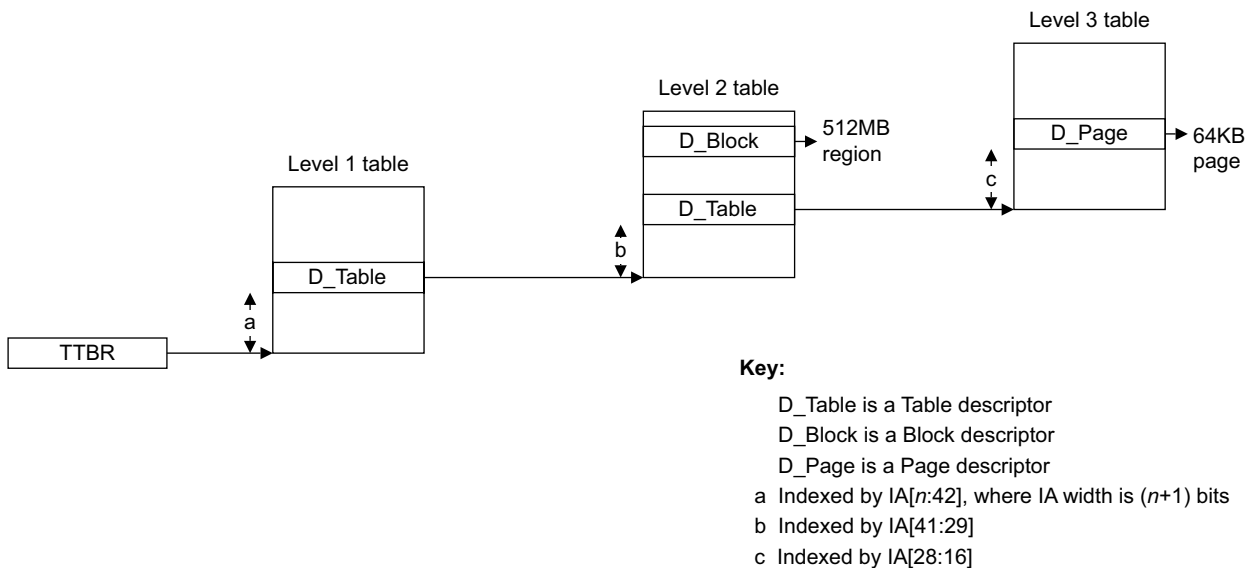

Figure D4-12 General view of VMSAv8-64 stage 1 address translation, 64KB granule

Overview of stage 2 translations, 64KB granule

For a stage 2 translation, up to 16 translation tables can be concatenated at the initial lookup level. For certain input address sizes, concatenating tables in this way means that the lookup starts at a lower level than would otherwise be the case. For more information see [Use of concatenated translation tables for the initial stage 2 lookup on page D4-1761](#).

When using the 64KB translation granule, [Table D4-18](#) shows all possibilities for the initial lookup for a stage 2 translation.

Table D4-18 VTCR_EL2.T0SZ values and IA ranges, 64K granule with possible concatenation of translation tables

| Tables ^a | T0SZ values and input address ranges ^b for starting at this level | | | | | | | | | |
|----------------------|--|---------------------|------|-----------|------|-----------|------|-----------|------|-----------|
| Initial lookup level | 1 | | 2 | | 4 | | 8 | | 16 | |
| | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA | T0SZ | IA |
| 1 | 16-21 | IA[47:16]-IA[42:16] | - | - | - | - | - | - | - | - |
| 2 | 22-34 | IA[41:16]-IA[29:16] | 21 | IA[42:16] | 20 | IA[43:16] | 19 | IA[44:16] | 18 | IA[45:16] |
| 3 | 35-39 | IA[28:16]-IA[24:16] | 34 | IA[29:16] | 33 | IA[30:16] | 32 | IA[31:16] | 31 | IA[32:16] |

- a. Number of concatenated translation tables at the initial lookup level. *1 table* corresponds to no concatenation, also shown in [Table D4-17 on page D4-1753](#).
- b. The IAs shown in the table indicate the address bits to be resolved by an address translation addressing a page of memory, see the *Note* that follows.

Note

- When using the 64KB translation granule, there are no level 0 lookups.
- Because concatenating translation tables reduces the number of levels of lookup required, when using the 64KB translation granule, tables cannot be concatenated at level 1.
- Some bits of the IA do not require resolution by the translation table lookup, because they always map directly to the OA. When using the 64KB translation granule, IA[15:0] = OA[15:0] for all translations.

VTCR_EL2.SL0 indicates the required initial lookup level, as [Table D4-19](#) shows.

Table D4-19 VTCR_EL2.SL0 values, 64K granule

| Initial lookup level | VTCR_EL2.SL0 |
|----------------------|--------------|
| 1 | 0b10 |
| 2 | 0b01 |
| 3 | 0b00 |

The VTCR_EL2.SL0 value 0b11 is reserved.

Because the maximum number of concatenated translation tables is 16, there is a relationship between the permitted VTCR_EL2.{T0SZ, SL0} values. [Table D4-18](#) shows the permitted values of T0SZ for each initial lookup level.

If, when a translation table walk is started, the T0SZ value is not consistent with the SL0 value, or VTCR_EL2.SL0 is programmed to a reserved value, a stage 2 level 0 Translation fault is generated.

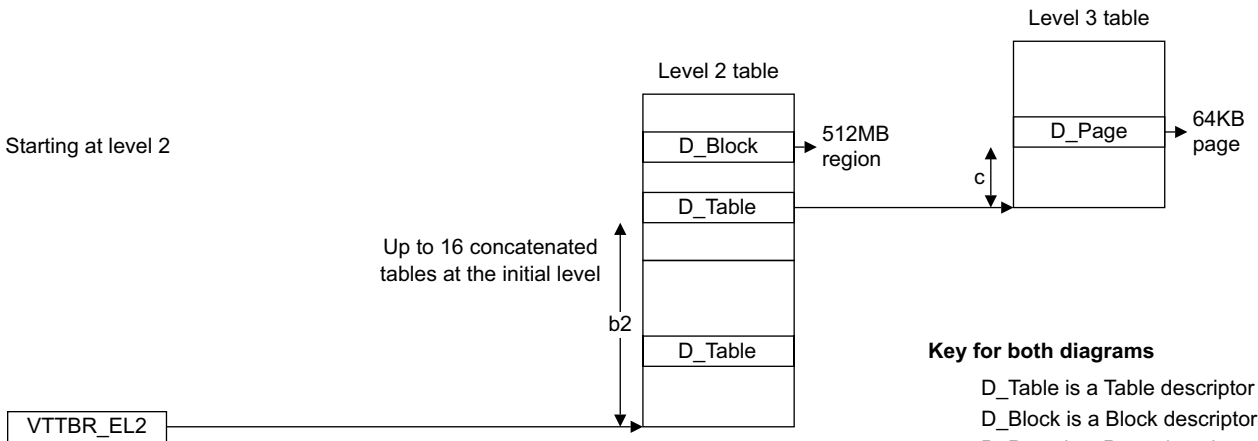

Figure D4-13 shows the stage 2 address translation, for an input address size of between 43 and 46 bits. This means the lookup can start at either level 1 or level 2.

VTCR_EL2.SL0 defines the start level.

Starting at level 1

Starting at level 2

Key for both diagrams

- D_Table is a Table descriptor
- D_Block is a Block descriptor
- D_Page is a Page descriptor
- a Indexed by IA[n:42], where IA width is (n+1) bits
- b1 Indexed by IA[41:29]
- b2 Indexed by IA[n:29], where IA width is (n+1) bits
- c Indexed by IA[28:16]

Figure D4-13 General view of VMSAv8-64 stage 2 address translation, 64KB granule

D4.2.6 The VMSAv8-64 translation table format

This section provides the full description of the VMSAv8-64 translation table format, its use for address translations that are controlled by an Exception level using AArch64. For these translation regimes:

For a stage 1 translation that supports two VA ranges

- For the lower VA range, that uses [TTBR0_ELx](#):
 - The [TCR_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
 - The [TCR_ELx](#).TG0 field defines the Translation granule size.
- For the upper VA range, that uses [TTBR1_ELx](#):
 - The [TCR_ELx](#).{SH1, ORGN1, IRGN1} fields define memory region attributes for the translation table walks.
 - The [TCR_ELx](#).TG1 field defines the Translation granule size.
- Each of [TTBR0_ELx](#) and [TTBR1_ELx](#) contains an ASID field, and the [TCR_ELx](#).A1 field selects which of these specifies the [ASID](#) to use.

For a stage 1 translation that supports one VA range

The translation table walks use [TTBR0_ELx](#), and:

- The [TCR_ELx](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [TCR_ELx](#).TG0 field defines the Translation granule size.

For a stage 2 translation

The translation table walks use [VTTBR_EL2](#), and:

- The [VTCR_EL2](#).{SH0, ORGN0, IRGN0} fields define memory region attributes for the translation table walks.
- The [VTCR_EL2](#).TG0 field defines the Translation granule size.

For the VMSAv8-64 translation table format, [Overview of the VMSAv8-64 address translation stages](#) on page D4-1745 summarizes the lookup levels, and [Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats](#) on page D4-1775 describes the translation table entries.

The following subsections describe the use of this translation table format:

- [Translation granule size and associate block and page sizes](#) on page D4-1757.
- [Selection between TTBR0 and TTBR1 when two VA ranges are supported](#) on page D4-1759.
- [Use of concatenated translation tables for the initial stage 2 lookup](#) on page D4-1761.
- [Possible translation table registers programming errors](#) on page D4-1762.

Translation granule size and associate block and page sizes

Table D4-20 shows the supported granule sizes, block sizes and page sizes, for the different granule sizes. For completeness, this table includes information for AArch32 state. In the table, the OA bit ranges are the OA bits that the translation table descriptor specifies to address the block or page of memory, in an implementation that supports a 48-bit OA range.

Table D4-20 Translation table granule sizes, with block and page sizes, and output address ranges

| Granule size | Table level | Block size and OA bit range | Page size and OA bit range |
|--------------|-------------|-----------------------------|----------------------------|
| 4KB | Zero | - | - |
| | One | 1GB, OA[47:30] | - |
| | Two | 2MB, OA[47:21] | - |
| | Three | - | 4KB, OA[47:12] |
| 16KB | Zero | - | - |
| | One | - | - |
| | Two | 32MB, OA[47:25] | - |
| | Three | - | 16KB, OA[47:14] |
| 64KB | One | - | - |
| | Two | 512MB, OA[47:29] | - |
| | Three | - | 64KB, OA[47:16] |

Bit[1] of a translation table descriptor identifies whether the descriptor is a block descriptor, and:

- The 4KB granule size supports block descriptors only in level 1 and level 2 translation tables.
- The 16KB and 64KB granule sizes support block descriptors only in level 2 translation tables,

If bit[1] of a descriptor is 0 in a translation table that does not support block descriptors then a translation table walk that accesses that descriptor generates a Translation fault.

For translations managed from AArch64 state, the following tables expand the information for each granule size, showing for an access to a single translation table at each lookup level:

- The maximum IA size, and the address bits that are resolved for that maximum size.
- The maximum OA range resolved by the translation table descriptors at this level, and the corresponding memory region size.
- The maximum size of the translation table. This is the size required for the maximum IA size.

Table D4-21 on page D4-1758 shows this information for the 4KB translation granule size, Table D4-22 on page D4-1758 shows this information for the 16KB translation granule size, and Table D4-23 on page D4-1758 shows this information for the 64KB translation granule size.

Table D4-21 Properties of the address lookup levels, 4KB granule size

| Level | Maximum input address | | Maximum output address | | Number of entries | Block entries supported? |
|-------|-----------------------|----------------|------------------------|---------------------------------------|-------------------|--------------------------|
| | Size | Address range | Address range | Size of addressed region ^a | | |
| Zero | 256TB | Address[47:39] | Address[47:39] | 512GB | Up to 512 | No |
| One | 512GB | Address[38:30] | Address[47:30] | 1GB | Up to 512 | Yes |
| Two | 1GB | Address[29:21] | Address[47:21] | 2MB | Up to 512 | Yes |
| Three | 2MB | Address[20:12] | Address[47:12] | 4KB | 512 | Page only |

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

Table D4-22 Properties of the address lookup levels, 16KB granule size

| Level | Maximum input address | | Maximum output address | | Number of entries | Block entries supported? |
|-------|-----------------------|----------------|------------------------|---------------------------------------|-------------------|--------------------------|
| | Size | Address range | Address range | Size of addressed region ^a | | |
| Zero | 256TB | Address[47] | Address[47] | 128TB | 2 ^b | No |
| One | 128TB | Address[46:36] | Address[47:36] | 64GB | Up to 2048 | No |
| Two | 64GB | Address[35:25] | Address[47:25] | 32MB | Up to 2048 | Yes |
| Three | 32MB | Address[24:14] | Address[47:14] | 16KB | 2048 | Page only |

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

Table D4-23 Properties of the address lookup levels, 64KB granule size

| Level | Maximum input address | | Maximum output address | | Number of entries | Block entries supported? |
|-------|-----------------------|----------------|------------------------|---------------------------------------|-----------------------|--------------------------|
| | Size | Address range | Address range | Size of addressed region ^a | | |
| One | 256TB | Address[47:42] | Address[47:42] | 4TB | Up to 64 ^b | No |
| Two | 4TB | Address[41:29] | Address[47:29] | 512MB | Up to 8192 | Yes |
| Three | 512MB | Address[28:16] | Address[47:16] | 64KB | 8192 | Page only |

a. That is, the size of the region either addressed by descriptors at this level or to be resolved at this and the subsequent levels of lookup.

b. The translation table size is less than the maximum for this granule size, and therefore the number of entries is reduced.

For the initial lookup level:

- If the IA range specified by the `TCR.TxSZ` field is smaller than the maximum size shown in these table then this reduces the number of addresses in the table and therefore reduces the table size. The smaller translation table is aligned to its table size.
- For stage 2 translations, multiple translation tables can be concatenated to extend the maximum IA size beyond that shown in these tables. For more information see the stage 2 translation overviews in *Overview of the VMSAv8-64 address translation stages on page D4-1745* and *Use of concatenated translation tables for the initial stage 2 lookup on page D4-1761*.

If a supplied input address is larger than the configured input address size, a Translation fault is generated.

———— **Note** ————

Larger translation granule sizes typically requires fewer levels of translation tables to translate a particular size of VA.

For the `TCR` programming requirements for the initial lookup, see *Overview of the VMSAv8-64 address translation stages on page D4-1745*.

Selection between TTBR0 and TTBR1 when two VA ranges are supported

Every translation table walk starts by accessing the translation table addressed by the `TTBR` for the stage 1 translation for the required translation regime.

For a stage 1 translation that supports two VA ranges, [Figure D4-14](#) shows this VA range split, and:

- `TTBR0_ELx` points to the initial translation table for the lower VA range, that starts at address `0x0000_0000_0000_0000`,
- `TTBR1_ELx` points to the initial translation table for the upper VA range, that runs up to address `0xFFFFFFFFFFFFFFFF`.

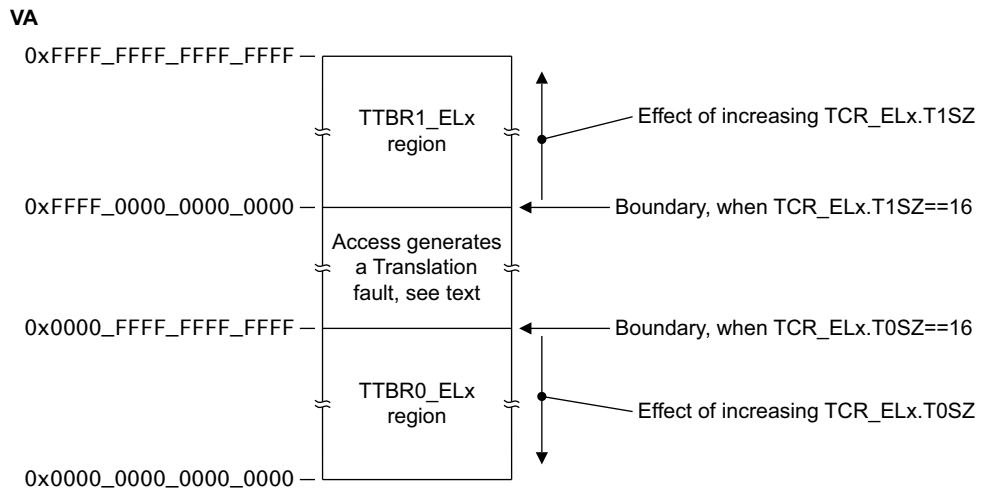

Figure D4-14 AArch64 `TTBRn` boundaries and VA ranges

Which `TTBR` is used depends only on the VA presented for translation:

- If the top bits of the VA are zero, then `TTBR0_ELx` is used.
- If the top bits of the VA are one, then `TTBR1_ELx` is used.

It is configurable whether this determination depends on the values of `VA[63:56]` or on the values of `VA[55:48]`, see *Address tagging in AArch64 state on page D4-1724*.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the `TCR_ELx.TnSZ` values and the region for which an access generates a Translation fault is wider than shown in [Figure D4-14 on page D4-1759](#). That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. [Possible translation table registers programming errors on page D4-1762](#) describes this possibility.

[Example D4-3](#) shows a typical application of this VA split.

Example D4-3 Example use of the split VA range, and the TTBR0_ELx and TTBR1_ELx controls

An example of using the split VA range is:

TTBR0_ELx Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- `TTBR0_ELx` is updated to point to the level 1 translation table for the new context
- `TCR_ELx` is updated if this change changes the size of the translation table
- `CONTEXTIDR_ELx` is updated.

TTBR1_ELx Used for operating system and I/O addresses, that do not change on a context switch.

For each VA subrange, the input address size is $2^{(64-TnSZ)}$, where `TnSZ` is one of `TCR_EL1.{T0SZ, T1SZ}`,

This means the two VA subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to $(2^{(64-T0SZ)} - 1)$.

Upper VA subrange $(2^{64} - 2^{(64-T1SZ)})$ to `0xFFFF_FFFF_FFFF_FFFF`.

The minimum `TnSZ` value is 16, corresponding to the maximum input address range of 48 bits. [Example D4-4](#) shows the two VA subranges when `T0SZ` and `T1SZ` are both set to this minimum value.

Example D4-4 Maximum VA ranges when a stage of translation supports two ranges

The maximum VA subranges correspond to `T0SZ` and `T1SZ` each having the minimum value of 16. In this case the subranges are:

Lower VA subrange `0x0000_0000_0000_0000` to `0x0000_FFFF_FFFF_FFFF`.

Upper VA subrange `0xFFFF_0000_0000_0000` to `0xFFFF_FFFF_FFFF_FFFF`.

[Figure D4-14 on page D4-1759](#) indicates the effect of varying the `TnSZ` values.

As described in [Overview of the VMSAv8-64 address translation stages on page D4-1745](#), the `TnSZ` values also determine the initial lookup level for the translation.

Use of concatenated translation tables for the initial stage 2 lookup

Overview of the VMsAv8-64 address translation stages on page D4-1745 introduced the ability to concatenate translation tables for the initial stage 2 translation lookup. This section gives more information about that concatenation.

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

When using the 16KB translation granule, if a 48-bit input address size is required for the stage 2 translations, lookup must start with two concatenated translation tables at level 1.

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program `VTTBR_EL2` to hold the address of the first of the concatenated translation tables.
- Program `VTCR_EL2` to indicate the required input address range and initial lookup level.

———— Note —————

The use of concatenated translation tables avoids the overhead of an additional level of translation.

Concatenating additional translation tables at the initial level of look up resolves additional address bits at that level. To resolve n additional address bits requires 2^n concatenated translation tables. [Example D4-5](#) shows how, for level 1 lookups using the 4KB translation granule, translation tables can be concatenated to resolve three additional address bits.

Example D4-5 Adding three bits of address resolution at level 1 lookup, using the 4KB granule

When using the 4KB translation granule, a level 1 lookup with a single translation table resolves address bits[38:30]. To add three more address bits requires 2^3 translation tables, that is, eight translation tables. This means:

- The total size of the concatenated translation tables is $8 \times 4\text{KB} = 32\text{KB}$.
- This block of concatenated translation tables must be aligned to 32KB.
- The address range resolved at this lookup level is A[41:30], of which:
 - Bits A[41:39] select the 4KB translation table.
 - Bits A[38:30] index a descriptor within that translation table.

As an example of the concatenation of translation tables at the initial lookup level, when using the 4KB translation granule, [Table D4-24](#) shows the possible uses of concatenated translation tables to permit lookup to start at level 1 rather than at level 0. For completeness, the table starts with the case where the required IPA range means lookup starts at level 1 with a single translation table at that level.

Table D4-24 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule

| Configured stage 2 IA size | | Lookup starts at level 0 | Lookup starts at level 1 | |
|----------------------------|-----------------------|--------------------------|-------------------------------|---------------------------------|
| IPA range | Size | Required level 0 entries | Number of concatenated tables | Required alignment ^a |
| IPA[38:0] | 2 ³⁶ bytes | - | 1 | 4KB |
| IPA[39:0] | 2 ³⁷ bytes | 2 | 2 | 8KB |

Table D4-24 Possible uses of concatenated translation tables for level 1 lookup, 4KB granule (continued)

| Configured stage 2 IA size | | Lookup starts at level 0 | Lookup starts at level 1 | |
|----------------------------|-----------------------|--------------------------|-------------------------------|---------------------------------|
| IPA range | Size | Required level 0 entries | Number of concatenated tables | Required alignment ^a |
| IPA[40:0] | 2 ³⁸ bytes | 4 | 4 | 16KB |
| IPA[41:0] | 2 ³⁹ bytes | 8 | 8 | 32KB |
| IPA[42:0] | 2 ⁴⁰ bytes | 16 | 16 | 64KB |

a. Required alignment of the set of concatenated level 2 tables.

Note

Because concatenation is permitted only for a stage 2 translation, the input addresses in the table are [IPAs](#).

[Overview of the VMSAv8-64 address translation stages on page D4-1745](#) identifies all of the possible uses of concatenation. In all cases, the block of concatenated translation tables must be aligned to the block size.

Possible translation table registers programming errors

This subsection describes possible errors in programming the translation table registers.

Misprogramming the `VTCCR_EL2.{T0SZ, SL0}` fields

For a stage 2 translation, the programming of the `VTCCR_EL2.{T0SZ, SL0}` fields must be consistent. If these fields are not consistent, or if `SL0` is programmed to a reserved value, any translation table walk that uses stage 2 translation generates a stage 2 level 0 Translation fault. For more information see [Overview of the VMSAv8-64 address translation stages on page D4-1745](#).

Misprogramming of the Contiguous bit

For more information about the Contiguous bit, and the range of translation table entries that must have the bit set to 1 to mark the entries as contiguous, see [The Contiguous bit on page D4-1796](#).

If one or more of the following errors is made in programming the translation tables, the TLB might contain overlapping entries:

- One or more of the contiguous translation table entries does not have the Contiguous bit set to 1.
- One or more of the contiguous translation table entries holds an output address that is not consistent with all of the entries pointing to the same aligned contiguous address range.
- The attributes and permissions of the contiguous entries are not all the same.

Such misprogramming of the translation tables means the output address, memory permissions, or attributes for a lookup might be corrupted, and might be equal to values that are not consistent with any of the programmed translation table values.

In some implementations, such misprogramming might also give rise to a TLB Conflict abort.

The architecture guarantees that misprogramming of the Contiguous bit cannot provide a mechanism for any of the following to occur:

- Software executing at EL1 or EL0 accessing regions of physical memory that are not accessible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.
- Software executing at EL1 or EL0 accessing regions of physical memory with attributes or permissions that are not possible by programming the translation tables, from EL1, with arbitrary chosen values that do not misprogram the Contiguous bit.

- Software executing in Non-secure state accessing Secure physical memory.

———— **Note** —————

Hardware implementations must ensure that use of the Contiguous bit cannot provide a mechanism for avoiding output address range checking. This might occur if a Contiguous bit block size of 0.5 GB or 1 GB is used in a system with the output address size configured to 4 GB. The architecture permits the implemented mechanism for preventing any avoidance of output address range checking to suppress the use of the Contiguous bit for such entries in such a system.

Where the Contiguous bit is used to mark a set of blocks as contiguous, if the address range translated by a set of blocks marked as contiguous is larger than the size of the input address supported at a stage of translation used to translate that address at that stage of translation, as defined by the `TCR.TxSZ` field, then this is a programming error. An implementation is permitted, but not required, to:

- Treat such a block within a contiguous set of blocks as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation, as defined by the `TCR.TxSZ` field.
- Treat such a block within a contiguous set of blocks as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, as defined by the `TCR.TxSZ` field, provided that both of the following apply:
 - The block is valid.
 - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

D4.2.7 The algorithm for finding the translation table descriptors

This subsection gives the algorithms for finding the translation table descriptor that corresponds to a given IA, for each required level of lookup. The algorithms encode the descriptions of address translation given earlier in this section. The algorithm details depend on the translation granule size for the stage of address translation, see:

- [Finding the translation table descriptor when using the 4KB translation granule on page D4-1764.](#)
- [Finding the translation table descriptor when using the 16KB translation granule on page D4-1765.](#)
- [Finding the translation table descriptor when using the 64KB translation granule on page D4-1766.](#)

Each subsection uses the following terms:

- BaseAddr** The base address for the level of lookup, as defined by:
- For the initial lookup level, the value of the appropriate `TTBR.BADDR` field.
 - Otherwise, the translation table address returned by the previous level of lookup.
- PAMax** The supported `PA` width, in bits.
- IA** The supplied IA for this stage of translation.
- TnSZ** The translation table size for this stage of translation:
- For EL1&0 stage 1** `TCR_EL1.T0SZ` or `TCR_EL1.T1SZ`, as appropriate.
 - For EL1&0 stage 2** `VTCR_EL2.T0SZ`.
 - For EL2 stage 1** `TCR_EL2.T0SZ`.
 - For EL3 stage 1** `TCR_EL3.T0SZ`.
- SL0** `VTCR_EL2.SL0`. Applies to the Non-secure EL1&0 stage 2 translation only.

These subsections show only architecturally-valid programming of the `TCR`. See also [Possible translation table registers programming errors on page D4-1762](#).

Finding the translation table descriptor when using the 4KB translation granule

Table D4-25 shows the translation table descriptor address, for each level of lookup, when using the 4KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-1763 for more information about terms used in the table.

Table D4-25 Translation table entry addresses when using the 4KB translation granule

| Lookup level | Entry address and conditions | | General conditions |
|--------------|---|--|--------------------|
| | Stage 1 translation | Stage 2 translation | |
| Zero | BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if ^a $16 \leq TnSZ \leq 24$ then $x = (28 - TnSZ)$ | BaseAddr[PAMax-1:x]:IA[y:39]:0b000 if $SL0^b == 2$ then if ^a $16 \leq T0SZ \leq 24$ then $x = (28 - T0SZ)$ | $y = (x + 35)$ |
| One | BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if ^a $25 \leq TnSZ \leq 33$ then $x = (37 - TnSZ)$ else ^c $x = 12$ | BaseAddr[PAMax-1:x]:IA[y:30]:0b000 if $SL0^b == 1$ then if ^a $21 \leq T0SZ \leq 33$ then $x = (37 - T0SZ)$ elseif $SL0^{b,c} == 2$ then $x = 12$ | $y = (x + 26)$ |
| Two | BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if ^a $34 \leq TnSZ \leq 39$ then $x = (46 - TnSZ)$ else ^c $x = 12$ | BaseAddr[PAMax-1:x]:IA[y:21]:0b000 if $SL0^b == 0$ then if ^a $30 \leq T0SZ \leq 39$ then $x = (46 - T0SZ)$ elseif $SL0^{b,c} > 0$ then $x = 12$ | $y = (x + 17)$ |
| Three | BaseAddr[PAMax-1:12]:IA[20:12]:0b000 | BaseAddr[PAMax-1:12]:IA[20:12]:0b000 | - |

- This line indicates the range of permitted values for $TnSZ$, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 4KB translation granule* on page D4-1745.
- $SL0 == 0$ if the initial lookup is level 2, $SL0 == 1$ if the initial lookup is level 1, and $SL0 == 2$ if the initial lookup level is level 0.
- This is the case where this level of lookup is not the initial level of lookup.

Table D4-7 on page D4-1736 shows how software can determine whether an implementation supports the 4KB granule size.

Finding the translation table descriptor when using the 16KB translation granule

Table D4-26 shows the translation table descriptor address, for each level of lookup, when using the 16KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-1763 for more information about terms used in the table.

Table D4-26 Translation table entry addresses when using the 16KB translation granule

| Lookup level | Entry address and conditions | | General conditions |
|--------------|---|---|-------------------------|
| | Stage 1 translation | Stage 2 translation | |
| Zero | BaseAddr[PAMax-1:4]:IA[47]:0b000 ^a $16 \leq TnSZ$ | - | Only applies to stage 1 |
| One | BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if ^a $17 \leq TnSZ \leq 27$ then $x = (31 - TnSZ)$ else ^c $x = 14$ | BaseAddr[PAMax-1:x]:IA[y:36]:0b000 if $SL0^b == 2$ then if ^a $16 \leq T0SZ \leq 27$ then $x = (31 - T0SZ)$ | $y = (x + 32)$ |
| Two | BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if ^a $28 \leq TnSZ \leq 38$ then $x = (42 - TnSZ)$ else ^c $x = 14$ | BaseAddr[PAMax-1:x]:IA[y:25]:0b000 if $SL0^b == 1$ then if ^a $24 \leq T0SZ \leq 38$ then $x = (42 - T0SZ)$ elsif $SL0^b, ^c == 2$ then $x = 14$ | $y = (x + 21)$ |
| Three | BaseAddr[PAMax-1:14]:IA[24:14]:0b000 | BaseAddr[PAMax-1:x]:IA[y:14]:0b000 if $SL0^b == 0$ then if ^a $35 \leq T0SZ \leq 39$ then $x = (53 - T0SZ)$ elsif $SL0^b, ^c > 0$ then $x = 14$ | $y = (x + 10)$ |

- a. This line indicates the range of permitted values for $TnSZ$, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 16KB translation granule* on page D4-1749.
- b. $SL0 == 0$ if the initial lookup is level 3, $SL0 == 1$ if the initial lookup is level 2, and $SL0 == 2$ if the initial lookup level is level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.

Table D4-7 on page D4-1736 shows how software can determine whether an implementation supports the 16KB granule size.

Finding the translation table descriptor when using the 64KB translation granule

Table D4-27 shows the translation table descriptor address, for each level of lookup, when using the 64KB translation granule. See the start of *The algorithm for finding the translation table descriptors* on page D4-1763 for more information about terms used in the table.

Table D4-27 Translation table entry addresses when using the 64KB translation granule

| Lookup level | Entry address and conditions | | General conditions |
|--------------|---|---|--------------------|
| | Stage 1 translation | Stage 2 translation | |
| One | BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if ^a $16 \leq TnSZ \leq 21$ then $x = (25 - TnSZ)$ | BaseAddr[PAMax-1:x]:IA[y:42]:0b000 if $SL0^b == 2$ then if ^a $16 \leq T0SZ \leq 21$ then $x = (25 - T0SZ)$ | $y = (x + 38)$ |
| Two | BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if ^a $22 \leq TnSZ \leq 34$ then $x = (38 - TnSZ)$ else ^c $x = 16$ | BaseAddr[PAMax-1:x]:IA[y:29]:0b000 if $SL0^b == 1$ then if ^a $18 \leq T0SZ \leq 34$ then $x = (38 - T0SZ)$ elsif $SL0^{b,c} == 2$ then $x = 16$ | $y = (x + 25)$ |
| Three | BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if ^a $35 \leq TnSZ \leq 39$ then $x = (51 - TnSZ)$ else ^c $x = 16$ | BaseAddr[PAMax-1:x]:IA[y:16]:0b000 if $SL0^b == 0$ then if ^a $31 \leq T0SZ \leq 39$ then $x = (51 - T0SZ)$ elsif $SL0^{b,c} > 0$ then $x = 16$ | $y = (x + 12)$ |

- a. This line indicates the range of permitted values for $TnSZ$, for a lookup that starts at this level, see *Overview of VMSAv8-64 address translation using the 64KB translation granule* on page D4-1753.
- b. $SL0 == 0$ if the initial lookup is level 3, $SL0 == 1$ if the initial lookup is level 2, and $SL0 == 2$ if the initial lookup level is at level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.

Table D4-7 on page D4-1736 shows how software can determine whether an implementation supports the 64KB granule size.

D4.2.8 The effects of disabling a stage of address translation

The following sections describe the effect on MMU behavior of disabling each stage of translation:

- [Behavior when stage 1 address translation is disabled.](#)
- [Behavior when stage 2 address translation is disabled on page D4-1768.](#)
- [Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1768.](#)

Behavior when stage 1 address translation is disabled

When a stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of translation are treated as follows:

Non-secure EL1 and EL0 accesses if the [HCR_EL2.DC](#) bit is set to 1

For the Non-secure EL1&0 translation regime, when the value of [HCR_EL2.DC](#) is 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

———— **Note** —————

This applies for both instruction and data accesses.

—————

All other accesses

For all other accesses, when stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns the Normal memory attribute, with the cacheability and shareability attributes determined by the value of the [SCTLR.I](#) bit for the translation regime, as follows:

When the value of I is 0

The stage 1 translation assigns the Non-cacheable and Outer Shareable attributes.

When the value of I is 1

The stage 1 translation assigns the Cacheable, Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Outer Shareable attribute.

For this stage of translation, no memory access permission checks are performed. Therefore no MMU faults can be generated for this stage of address translation.

———— **Note** —————

Alignment checking is performed, and therefore Alignment faults can occur.

—————

For every access, the input address of the stage 1 translation is flat-mapped to the output address.

For a Non-secure EL1 or EL0 access, if EL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

When the value of [HCR_EL2.DC](#) is 1, in Non-secure state:

- The [SCTLR_EL1.M](#) bit behaves as if it is 0, for all purposes other than reading the value of the bit. This means Non-secure EL1&0 stage 1 address translation is disabled.
- The [HCR_EL2.VM](#) bit behaves as if it is 1, for all purposes other than reading the value of the bit. This means that Non-secure EL1&0 stage 2 address translation is enabled.

See also [Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1768.](#)

Effect of disabling address translation on maintenance and address translation instruction instructions

Cache maintenance instructions act on the target cache regardless of whether any stages of address translation are disabled, and regardless of the values of the memory attributes. However, if a stage of address translation is disabled, they use the flat address mapping for that translation stage.

TLB invalidate operations act on the target TLB regardless of whether any stage of address translation is disabled.

The value of [HCR_EL2.DC](#) affect some address translation instructions, see [Address translation instructions, AT*](#) on page D4-1771.

Behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The [IPA](#) output from the stage 1 translation maps flat to the [PA](#).
- The memory attributes and permissions from the stage 1 translation apply to the [PA](#).

When both stages of address translation are disabled, see also [Behavior of instruction fetches when all associated stages of translation are disabled](#).

Behavior of instruction fetches when all associated stages of translation are disabled

When EL3 is using AArch64, this section applies to:

- The Secure EL1&0 translation regime when Secure EL1&0 stage 1 address translation is disabled.
- The Secure EL3 translation regime, when Secure EL3 stage 1 address translation is disabled.
- The Non-secure EL2 translation regime, when Non-secure EL2 stage 1 address translation is disabled
- The Non-secure EL1&0 translation regime, when both stages of address translation are disabled.

Note

- The behaviors in Non-secure state apply regardless of the Execution state that EL3 is using.
- When the value of [HCR_EL2.DC](#) is 1, then the behavior of the Non-secure EL1&0 translation regime is as if stage 1 translation is disabled and stage 2 translation is enabled, as described in [Behavior when stage 1 address translation is disabled on page D4-1767](#).

In these cases, when execution is in AArch64 state, a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same block of memory as, or in the next contiguous block of memory to, an instruction that a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
 - The last reset.
 - The last synchronization of instruction cache maintenance targeting the address of the branch instruction.

In this description, the blocks of memory referred to are of the size of the minimum implemented translation granule and are aligned to that size.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

———— **Note** ————

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when all associated stages of address translation are disabled are located in blocks of the address space, of the translation granule size, that contain only memory that is tolerant to speculative accesses.
- Each block of the address space, of the translation granule size, that immediately follows a similar block that holds instructions that will be executed when all associated stages address translation are disabled, contains only memory that is tolerant to speculative accesses.

D4.2.9 The implemented Exception levels and the resulting translation stages and regimes

Elsewhere, this chapter describes an implementation that includes all Exception levels, and describes the control of address translation by Exception levels that are using AArch64. This subsection describes how the address translation scheme changes if an implementation does not include all of the Exception levels.

If an implementation does not include EL3, it has only a single Security state, with MMU controls equivalent to the Secure state MMU controls.

If an implementation does not include EL2 then:

- If it also does not include EL3, the MMU provides only a single EL1&0 stage 1 translation regime.
- If it includes EL3, the MMU provides an EL1&0 stage 1 translation regime in each Security state.

[Figure D4-1 on page D4-1727](#) shows the set of translation regimes for an implementation that implements all of the Exception levels. [Table D4-28](#) shows how the supported translation stages depend on the implemented Exception levels, and in some cases on the Execution state being used by the highest implemented Exception level.

Table D4-28 The relation between the implemented translation stages and Exception levels for AArch64

| Translation stage | Requires |
|--------------------------|---|
| Secure EL3 stage 1 | EL3 implemented and using AArch64. |
| Secure EL1&0 stage 1 | Either: <ul style="list-style-type: none"> • EL3 implemented and using AArch64. • Only EL1 and EL0 implemented, all operation is in Secure state, and EL1 is using AArch64. |
| Non-secure EL2 stage 1 | EL2 implemented. |
| Non-secure EL1&0 stage 2 | EL2 implemented. |
| Non-secure EL1&0 stage 1 | Any implementation except: <ul style="list-style-type: none"> • Only EL1 and EL0 implemented, with all operation in the Secure state. |

D4.2.10 Pseudocode description of VMSAv8-64 address translation

The following subsections outline a pseudocode description of the translation table walk:

- [Definitions required for address translation on page D4-1770.](#)
- [Performing the full address translation on page D4-1770.](#)
- [Stage 1 translation on page D4-1770.](#)
- [Stage 2 translation on page D4-1770.](#)
- [Translation table walk on page D4-1770.](#)
- [Support functions on page D4-1770.](#)

Definitions required for address translation

In pseudocode, the result of a translation table lookup, in either Execution state, is returned in a [TLBRecord](#) structure.

[Memory data type definitions](#) on page D3-1717 includes definitions of the Permissions and AddressDescriptor parameters.

Performing the full address translation

The function [AArch64.FullTranslate\(\)](#) performs a full translation table walk. For any translation regime it performs a stage 1 translation for the supplied VA, and for the Non-secure EL1&0 translation regime it then performs a stage 2 translation of the returned address.

Stage 1 translation

The function [AArch64.FirstStageTranslate\(\)](#) performs a stage 1 translation, calling the function [AArch64.TranslationTableWalk\(\)](#), described in [Translation table walk](#), to perform the required translation table walk. However, if stage 1 translation is disabled, it calls the function [AArch64.TranslateAddressS10ff\(\)](#) to set the memory attributes.

Stage 2 translation

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. Function [AArch64.SecondStageWalk\(\)](#) performs this translation, by calling the [AArch64.SecondStageTranslate\(\)](#) function. When called from [AArch64.SecondStageWalk\(\)](#), the [AArch64.SecondStageTranslate\(\)](#) function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section.

Translation table walk

The function [AArch64.TranslationTableWalk\(\)](#) returns the result, in the form of a [TLBRecord](#), of a translation table walk made for a memory access from an Exception level that is using AArch64.

Support functions

In the translation table walk functions, the [WalkAttrDecode\(\)](#) function determines the attributes for a translation table lookup.

The function [AArch64.S1AttrDecode\(\)](#) decodes the attributes from a stage 1 translation table lookup.

The function [AArch64.CheckPermission\(\)](#) checks the access permissions returned by a stage 1 translation table lookup, see [Access permission checking](#) on page D3-1719.

The function [AArch64.CheckS2Permission\(\)](#) checks the access permissions returned by a stage 2 translation table lookup.

The function [AddrTop\(\)](#) returns the bit number of the most significant valid bit of a VA in the current translation regime. If EL1 is using AArch64 and EL0 is using AArch32 then an address from EL0 is zero-extended to 64 bits.

D4.2.11 Address translation instructions

Each of the ARMv8 instruction sets provides instructions that return the result of translating an input address, supplied as an argument to the instruction, using a specified translation stage or regime.

The available instructions only perform translations that are accessible from the Security state and Exception level at which the instruction is executed. That is:

- No instruction executed in Non-secure state can return the result of a Secure address translation stage.
- No instruction can return the result of an address translation stage that is controlled by an Exception level that is higher than the Exception level at which the instruction is executed.

*Address translation instructions, AT** summarizes the A64 address translation instructions.

See also *A64 system instructions for address translation on page C5-365*.

Address translation instructions, AT*

The A64 assembly language syntax for address translation instructions is:

```
AT <operation>, <Xt>
```

Where:

<operation> Is one of S1E1R, S1E1W, S1E0R, S1E0W, S12E1R, S12E1W, S12E0R, S12E0W, S1E2R, S1E2W, S1E3R, or S1E3W.

<operation> has a structure of <stages><level><read|write>, where:

<stages> Is one of:

S1 Stage 1 translation.

S12 Stage 1 translation followed by stage 2 translation.

<level> Describes the Exception Level that the translation applies to. Is one of:

E0 EL0.

E1 EL1.

E2 EL2.

E3 EL3.

If <level> is higher than the current Exception Level the instruction is UNDEFINED.

<read|write>

Is one of:

R Read.

W Write.

<Xt> The address to be translated. No alignment restrictions apply for the address.

If EL2 is not implemented, the AT S1E2R and AT S1E2W instructions are UNDEFINED.

————— Note —————

If EL2 is not implemented but EL3 is implemented, the AT S12E* instructions are not UNDEFINED, but behave the same way as the equivalent AT S1E* instructions. This is consistent with the behavior if EL2 is implemented but stage 2 translation is disabled.

In each case, the address being translated is held in the 64-bit address argument register, Xt. If the address translation instruction uses a translation regime that is using AArch32, meaning it requires a VA of only 32 bits, then VA[63:32] is RES0.

If the address translation is successful, the resulting PA is returned in PAR_EL1.PA, and PAR_EL1.F is set to 0 to indicate that the translation was successful. Otherwise, see *Synchronous faults generated by address translation instructions on page D4-1772*.

Note

The architecture provides a single PAR, [PAR_EL1](#), that is used regardless of:

- The Exception level at which the instruction was executed.
 - The Exception level that controls the stage or stages of translation used by the instruction.
-

For all of these instructions, the current context information determines which entries in TLB caching structures are used, and how the translation table walk is performed. However, it is IMPLEMENTATION DEFINED whether the Address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

When Non-secure EL1&0 stage 1 address translation is disabled, any AT S1E0*, AT S1E1*, AT S1E2E0*, or AT S1E2E1* address translation instruction that accesses the Non-secure state translation reflects the effect of the [HCR_EL2.DC](#) bit as described in *Behavior when stage 1 address translation is disabled on page D4-1767*.

Executing AT S1E2R or AT S1E2W at EL3 with [SCR_EL3.NS==0](#) is UNDEFINED.

Note

AT S1E* instructions at EL3 with [SCR_EL3.NS==0](#) are not UNDEFINED but behave the same way as the equivalent AT S1E* instructions.

Synchronous faults generated by address translation instructions

The address translation instructions use the translation mechanism, and that mechanism can generate the following synchronous faults:

- Translation fault.
- Access flag fault.
- Permission fault.
- Domain fault, when translating using the AArch32 translation systems.
- Address size fault.
- TLB conflict fault.
- Synchronous external aborts during a translation table walk.

In addition:

- If the address translation instruction requires two stages of translation then these faults could arise from either stage 1 or stage 2.
- For a stage 1 translation for the Non-secure EL1&0 translation regime, the fault might be generated on the stage 2 translation of an address accessed as part of the stage 1 translation table walk, see *Stage 2 fault on a stage 1 translation table walk on page D4-1806*.

Except as described in this section, these faults are not taken as an exception for the address translation instructions, but instead the [PAR_EL1.FST](#) field holds the fault status information. In these cases the [PAR_EL1.PA](#) field does not hold the output address of the translation.

The exceptions to this reporting the fault in [PAR_EL1](#) are:

- Synchronous external aborts during a translation table walk are taken as a Data Abort exception.
For an address translation instruction executed at a particular Exception level, if the synchronous external abort is generated on a stage 1 translation table walk, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 1 translation table walk for a memory access from that Exception level would be taken.

If the synchronous external abort is generated on a stage 2 translation table walk then:

- If the address translation instruction was executed at EL3, the synchronous Data Abort exception is taken to EL3.
- If the address translation instruction was executed at EL2 or EL1, the Data Abort exception is taken to the Exception level to which a synchronous external abort on a stage 2 translation table walk for a memory access from that Exception level would be taken.

In any case where the address translation instruction causes a synchronous Data Abort exception to be taken:

- The [PAR_EL1](#) is UNKNOWN.
 - The [ESR_ELx](#) of the target Exception Level of the exception indicates that the fault was due to a translation table walk for a cache maintenance instruction.
 - The [FAR_ELx](#) of the target Exception Level holds the [VA](#) for the translation request.
- For the AT S1E0* and AT S1E1* instructions executed from the Non-secure EL1 Exception level, if there is a synchronous stage 2 fault on a memory access made as part of the translation table walk then if the value of [SCR_EL3.EA](#) is 1 then a synchronous external abort on a stage 2 translation table walk is taken to EL3. In all other cases of a synchronous stage 2 fault on a memory access made as part of the translation table walk, the fault is taken as an exception to EL2, and:
 - [PAR_EL1](#) is UNKNOWN
 - [ESR_EL2](#) indicates that the fault occurred on a translation table walk, and that the operation that faulted was a cache maintenance instruction.
 - [HPFAR_EL2](#) holds the [IPA](#) that faulted
 - [FAR_EL2](#) holds the [VA](#) that the executing software supplied to the address translation instruction.

This fault can occur for any of the following reasons:

- Stage 2 Translation fault.
- Stage 2 Access fault.
- Stage 2 Permission fault.
- Stage 2 Address size fault.
- Synchronous external abort on a stage 2 translation table walk.

Synchronization requirements of the address translation instructions

Where an instruction results in an update to a System register, as is the case with the AT * address translation instructions, explicit synchronization must be performed before the result is guaranteed to be visible to subsequent direct reads of the [PAR_EL1](#).

Note

This is consistent with the AArch32 requirement, where the [VA](#) to [PA](#) translation instructions are executed as writes to the (coproc==0b1111) System register encoding space, and the effect of those writes to other registers require explicit synchronization before the result is guaranteed to be visible to subsequent instructions.

D4.3 VMSAv8-64 translation table format descriptors

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the ARMv8 translation table descriptor formats:

- [VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats](#).
- [ARMv8 translation table level 3 descriptor formats on page D4-1777](#).

[Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1778](#) then gives more information about the descriptor attribute fields, and [Control of Secure or Non-secure memory access on page D4-1782](#) describe how the NS and NSTable together control whether a memory access from Secure state accesses the Secure memory map or the Non-secure memory map.

D4.3.1 VMSAv8-64 translation table level 0, level 1, and level 2 descriptor formats

In the VMSAv8-64 translation table format, the difference in the formats of the level 0, level 1 and level 2 descriptors is:

- Whether a block entry is permitted.
- If a block entry is permitted, the size of the memory region described by that entry.

These differences depend on the translation granule, as follows:

4KB granule A level 0 descriptor does not support block translation.

A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

16KB granule Level 0 and level 1 descriptors do not support block translation.

A block entry in a level 2 table describes the mapping of the associated 32MB input address range.

64KB granule Level 0 lookup is not supported.

A level 1 descriptor does not support block translation.

A block entry in a level 2 table describes the mapping of the associated 512MB input address range.

[Figure D4-15 on page D4-1775](#) shows the ARMv8 level 0, level 1, and level 2 descriptor formats:

With the 4KB granule size, for the level 1 descriptor n is 30, and for the level 2 descriptor, n is 21.
 With the 16KB granule size, for the level 2 descriptor, n is 25.
 With the 64KB granule size, for the level 2 descriptor, n is 29.

With the 4KB granule size m is 12, with the 16KB granule size m is 14[‡], and with the 64KB granule size, m is 16[‡].

A level 0 Table descriptor returns the address of the level 1 table.
 A level 1 Table descriptor returns the address of the level 2 table.
 A level 2 Table descriptor returns the address of the level 3 table.

[‡] When $m > 12$, bits [(m-1):12] are RES0.

Figure D4-15 VMSAv8-64 level 0, level 1, and level 2 descriptor formats

Descriptor encodings, ARMv8 level 0, level 1, and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory, as follows:

4KB translation granule

- For a level 1 Block descriptor, bits[47:30] are bits[47:30] of the output address. This output address specifies a 1GB block of memory.
- For a level 2 descriptor, bits[47:21] are bits[47:21] of the output address. This output address specifies a 2MB block of memory.

16KB translation granule

For a level 2 Block descriptor, bits[47:25] are bits[47:25] of the output address. This output address specifies a 32MB block of memory.

64KB translation granule

For a level 2 Block descriptor, bits[47:29] are bits[47:29] of the output address. This output address specifies a 512MB block of memory.

Bits[63:52, 11:2] provide attributes for the target memory block, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1778](#). The position and contents of these bits are identical in the level 2 block descriptor and in the level 3 page descriptor.

Table descriptor

Gives the translation table address for the next-level lookup, as follows:

4KB translation granule

- Bits[47:12] are bits[47:12] of the address of the required next-level table, which is:
 - For a level 0 Table descriptor, the address of a level 1 table.
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[11:0] of the table address are zero.

16KB translation granule

- Bits[47:14] are bits[47:14] of the address of the required next-level table, which is:
 - For a level 0 Table descriptor, the address of a level 1 table.
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[13:0] of the table address are zero.

64KB translation granule

- Bits[47:16] are bits[47:16] of the address of the required next-level table, which is:
 - For a level 1 Table descriptor, the address of a level 2 table.
 - For a level 2 Table descriptor, the address of a level 3 table.
- Bits[15:0] of the table address are zero.

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1778](#).

If the translation table defines the Non-secure EL1&0 stage 1 translations, then the output address in the descriptor is the [IPA](#) of the target block or table. Otherwise, it is the [PA](#) of the target block or table.

D4.3.2 ARMv8 translation table level 3 descriptor formats

For the 4KB granule size, each entry in a level 3 table describes the mapping of the associated 4KB input address range.

For the 16KB granule size, each entry in a level 3 table describes the mapping of the associated 16KB input address range.

For the 64KB granule size, each entry in a level 3 table describes the mapping of the associated 64KB input address range.

Figure D4-16 shows the ARMv8 level 3 descriptor formats.

† Upper page attributes and Lower page attributes
‡ Field is RES0

Figure D4-16 VMSAv8-64 level 3 descriptor format

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page

Gives the address and attributes of a 4KB, 16KB, or 64KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Gives the output address of a page of memory, as follows:

4KB translation granule

Bits[47:12] are bits[47:12] of the output address for a page of memory.

16KB translation granule

Bits[47:14] are bits[47:14] of the output address for a page of memory.

64KB translation granule

Bits[47:16] are bits[47:16] of the output address for a page of memory.

Bits[63:52, 11:2] provide attributes for the target memory page, see [Memory attribute fields in the VMSAv8-64 translation table format descriptors on page D4-1778](#).

———— **Note** ————

The position and contents of bits[63:52, 11:2] are identical to bits[63:52, 11:2] in the level 0, level 1, and level 2 block descriptors.

For the Non-secure EL1&0 stage 1 translations, the output address in the descriptor is the [IPA](#) of the target page. Otherwise, it is the [PA](#) of the target page.

D4.3.3 Memory attribute fields in the VMSAv8-64 translation table format descriptors

[Memory region attributes on page D4-1792](#) describes the region attribute fields. The following subsections summarize the descriptor attributes as follows:

Table descriptor

Table descriptors for stage 2 translations do not include any attribute field. For a summary of the attribute fields in a stage 1 table descriptor, that define the attributes for the next lookup level, see [Next-level attributes in stage 1 VMSAv8-64 Table descriptors](#).

Block and page descriptors

These descriptors define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:

- [Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-1779](#)
- [Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors on page D4-1781](#).

Next-level attributes in stage 1 VMSAv8-64 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the attributes for the next-level translation table access, and bits[58:52] are IGNORED:

Next-level descriptor attributes, stage 1 only

† UXNTable for a translation regime that supports two VA ranges, XNTable for other regimes.
‡ Regimes that support two VA ranges only, RES0 in the other regimes.

These attributes are:

NSTable, bit[63]

For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses on page D4-1782](#).

For memory accesses from Non-secure state, including all accesses in the EL2 translation regime, this bit is RES0 and is ignored by the PE.

APTable, bits[62:61]

Access permissions limit for subsequent levels of lookup, see [Hierarchical control of data access permissions on page D4-1785](#).

APTable[0] is RES0:

- In the EL2 translation regime.
- In the EL3 translation regime.

UXNTable or XNTable, bit[60]

XN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D4-1789](#).

The naming of this field depends on whether the stage 1 translation supports two VA ranges:

Two VA ranges supported

This field is UXNTable, and determines whether execution at EL0 of instructions fetched from the region identified at a lower level of lookup permitted.

———— **Note** —————

PXNTable is the equivalent control of execution at a higher Exception level.

One VA range supported

This field is XNTable.

PXNTable, bit[59]

PXN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching on page D4-1789](#).

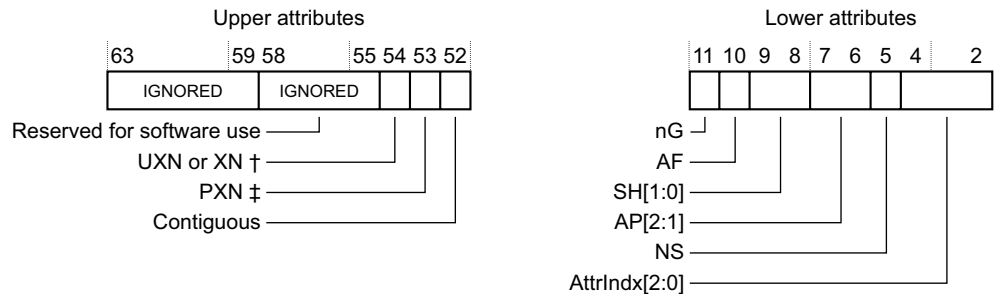

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-5718](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-1795](#).

Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 1 translation:

Attribute fields for VMSAv8-64 stage 1 Block and Page descriptors

† UXN for a translation regime that supports two VA ranges, XN for the other regimes.

‡ Regimes that support two VA ranges only, RES0 in the other regimes.

For a stage 1 descriptor, the attributes are:

UXN or XN, bit[54]

The Execute-never bit. Determines whether the region is executable, see [Access permissions for instruction execution on page D4-1786](#).

The naming of this field depends on whether the stage 1 translation supports two VA ranges:

Two VA ranges supported

This field is UXN (Unprivileged execute never), and determines whether execution at EL0 of instructions fetched from the region is permitted.

———— **Note** —————

PXN is the equivalent control of execution at a higher Exception level.

One VA range supported

This field is XN (Execute never).

PXN, bit[53] The Privileged execute-never bit. Determines whether the region is executable at EL1, see [Access permissions for instruction execution on page D4-1786](#).

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see [The Contiguous bit on page D4-1796](#).

nG, bit[11] The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See [Global and process-specific translation table entries on page D4-1812](#).

This field is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

AF, bit[10] The Access flag, see [The Access flag on page D4-1791](#).

SH, bits[9:8] Shareability field, see [Memory region attributes on page D4-1792](#).

AP[2:1], bits[7:6]

Data Access Permissions bits, see [Memory access control on page D4-1783](#).

————— **Note** —————

The ARMv8 translation table descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is valid only for a stage 1 translation that supports two VA ranges. It is RES0 for stage 1 translations that support only one VA range.

NS, bit[5] Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access on page D4-1782](#).

For memory accesses from Non-secure state, including all accesses in the EL2 translation regime, this bit is RES0 and is ignored by the PE.

AttrIdx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the MAIR_ELx, see [Stage 1 memory region type and Cacheability attributes on page D4-1792](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-5718](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-1795](#).

Attribute fields in stage 2 VMSAv8-64 Block and Page descriptors

In Block and Page descriptors, the memory attributes are split into an upper block and a lower block, as shown for a stage 2 translation:

Attribute fields for VMSAv8-64 stage 2 Block and Page descriptors

For a stage 2 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see [Access permissions for instruction execution on page D4-1786](#).

Contiguous, bit[52]

A hint bit indicating that the translation table entry is one of a contiguous set or entries, that might be cached in a single TLB entry, see [The Contiguous bit on page D4-1796](#).

AF, bit[10] The Access flag, see [The Access flag on page D4-1791](#).

SH, bits[9:8] Shareability field, see [The stage 2 memory region attributes, EL1&0 translation regime on page D4-1794](#).

S2AP, bits[7:6]

Stage 2 data Access Permissions bits, see [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1785](#).

Note

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see [The stage 2 memory region attributes, EL1&0 translation regime on page D4-1794](#).

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see [IGNORED on page Glossary-5718](#). For more information about these fields see [Other fields in the VMSAv8-64 translation table format descriptors on page D4-1795](#).

D4.3.4 Control of Secure or Non-secure memory access

As this section describes, the NS bit in the translation table entries:

- For accesses from Secure state, if the translation table entry was held in secure memory, determines whether the access is to Secure or Non-secure memory.
- Is ignored by:
 - Accesses from Non-secure state.
 - Accesses from Secure state if the translation table entry was held in Non-secure memory.

In the VMSAv8-64 translation table format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, that affects accesses at lower levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses](#).

The NS and NSTable bits are valid only for memory accesses from Secure state described by translation table descriptors that are fetched from Secure memory, and:

- In the translation table descriptors in a Non-secure translation table, the NS and NSTable bits are SBZ.
- Memory accesses from Non-secure state, including all accesses from EL2, ignore the values of these bits.

In the Secure translation regimes, for translation table descriptors that are fetched from Secure memory, the NS bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map, as follows:

NS == 0 Access the Secure PA space.
NS == 1 Access the Non-secure PA space.

For Non-secure translation regimes, and for translation table descriptors fetched from Non-secure memory, the corresponding bit is RES0 and is ignored by the PE. The access is made to Non-secure memory, regardless of the value of the bit.

Hierarchical control of Secure or Non-secure memory accesses

For VMSAv8-64 table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure PA space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure PA space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if nG==1, regardless of the value of the nG bit. For more information about the nG bit, see [Global and process-specific translation table entries on page D4-1812](#).

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

D4.4 Memory access control

The access control fields in the translation table descriptors determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [About access permissions.](#)
- [The data access permission controls on page D4-1784.](#)
- [Access permissions for instruction execution on page D4-1786.](#)
- [The Access flag on page D4-1791.](#)

Note

This section describes the access controls for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.

A translation applies to memory accesses from either:

- Only a single Exception level, for example the EL3 translation regime.
- EL0 and one higher Exception level, for example the EL1&0 translation regime.

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of the target memory region. These fields can be classified as address map control, access control, and region attribute fields. [Control of Secure or Non-secure memory access on page D4-1782](#) describes the address map control, and [Memory region attributes on page D4-1792](#) describes the other fields.

D4.4.1 About access permissions

Note

This section gives a general description of memory access permissions. In an implementation that includes EL2, software executing at EL1 in Non-secure state can see only the access permissions defined by the Non-secure EL1&0 stage 1 translations. However, software executing at EL2 can modify these permissions. This modification is invisible to the Non-secure software executing at EL1 or EL0.

The access permission bits control access to the corresponding memory region. The VMSAv8-64 translation table format:

- In stage 1 translations, uses AP[2:1] to define the data access permissions, see [The AP\[2:1\] data access permissions, for stage 1 translations on page D4-1784.](#)

Note

The description of the access permission field as AP[2:1] is for consistency with the VMSAv8-32 Short-descriptor translation table format, see [The VMSAv8-32 Short-descriptor translation table format on page G4-4040](#). The VMSAv8-64 translation table format does not define an AP[0] bit.

- In stage 2 translations, uses S2AP[1:0] to define the data access permissions, see [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1785.](#)
- Uses the UXN, XN and PXN bits to define access controls for instruction fetches, see [Access permissions for instruction execution on page D4-1786.](#)

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation.

———— **Note** ————

In an implementation that includes EL2, each stage of the translation of a memory access made using the Non-secure EL1&0 translation regime has its own, independent, permission check.

D4.4.2 The data access permission controls

The following subsections describe the data access permission controls:

- [The AP\[2:1\] data access permissions, for stage 1 translations.](#)
- [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1785.](#)
- [Hierarchical control of data access permissions on page D4-1785.](#)

The AP[2:1] data access permissions, for stage 1 translations

In VMSAv8-64, for a translation regime that applies to both EL0 and a higher Exception level, the AP[2:1] bits control the stage 1 data access permissions, and:

AP[2] Selects between read-only and read/write access.

AP[1] Selects between Application level (EL0) control and the higher Exception level control.

This provides four permission settings for data accesses:

- Read-only at all levels.
- Read/write at all levels.
- Read-only at the higher Exception level, no access by software executing at EL0.
- Read/write at the higher Exception level, no access by software executing at EL0.

———— **Note** ————

In ARMv8.0, the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime.

For translation regimes that apply only to accesses from a single Exception level, AP[2] determines the stage 1 data access permissions, and AP[1] is RES1, meaning it is ignored by hardware and is treated as if it is 1.

[Table D4-29](#) shows the meaning of the AP[2:1] field for stage 1 of a translation regime that applies to both EL0 and a higher Exception level. In this table, an entry of None indicates that any access from that Exception level faults.

Table D4-29 Data access permissions for stage 1 translations that applies to EL0 and a higher Exception level

| AP[2:1] | Access from higher Exception level | Access from EL0 |
|---------|------------------------------------|-----------------|
| 00 | Read/write | None |
| 01 | Read/write | Read/write |
| 10 | Read-only | None |
| 11 | Read-only | Read-only |

For the Non-secure EL1&0 translation regime:

- The stage 2 translation also defines data access permissions, see [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1785.](#)
- When both stages of translation are enabled, [Combining the stage 1 and stage 2 data access permissions on page D4-1797](#) describes how these permissions are combined.

Table D4-30 shows the effect of the AP[2] field for stage 1 of a translation regime that applies to only a single Exception level.

Table D4-30 Data access permissions for stage 1 translations that apply to only a single Exception level

| AP[2] | Access permission |
|-------|-------------------|
| 0 | Read/write |
| 1 | Read-only |

The S2AP data access permissions, Non-secure EL1&0 translation regime

In the Non-secure EL1&0 translation regime, when stage 2 address translation is enabled, the S2AP field in the stage 2 translation table descriptors define the data access permissions as Table D4-31 shows. In this table, an entry of None indicates that any access generates a Permission fault.

Table D4-31 Data access permissions for stage 2 of the Non-secure EL1&0 translation regime

| S2AP | Access from Non-secure EL1 or Non-secure EL0 |
|------|--|
| 00 | None |
| 01 | Read-only |
| 10 | Write-only |
| 11 | Read/write |

The S2AP access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined by AP[2:1], see [Combining the stage 1 and stage 2 data access permissions on page D4-1797](#).

[Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1797](#) gives more information about the use of the stage 1 and stage 2 access permissions in an implementation of virtualization.

Hierarchical control of data access permissions

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the data access permissions.

———— **Note** —————

Similar hierarchical controls apply to instruction fetching, see [Hierarchical control of instruction fetching on page D4-1789](#).

The restrictions apply only to subsequent levels of lookup for the same stage of translation. The APTable[1:0] field restricts the access permissions, as Table D4-32 shows.

As stated in the table footnote, for a translation regime that applies to only a single Exception level, APTable[0] is RES0, meaning it is ignored by the hardware.

Table D4-32 Effect of APTable[1:0] on subsequent levels of lookup

| APTable[1:0] | Effect |
|--------------|--|
| 00 | No effect on permissions in subsequent levels of lookup. |

Table D4-32 Effect of APTable[1:0] on subsequent levels of lookup (continued)

| APTable[1:0] | Effect |
|---------------------|--|
| 01 ^a | Access at EL0 not permitted, regardless of permissions in subsequent levels of lookup. |
| 10 | Write access not permitted, at any Exception level, regardless of permissions in subsequent levels of lookup. |
| 11 ^a | Regardless of permissions in subsequent levels of lookup: <ul style="list-style-type: none"> • Write access not permitted, at any Exception level. • Read access not permitted at EL0. |

a. Not valid any translation regime that applies to only a single Exception level. In the translation tables for such a regime, APTable[0] is RES0.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The VMSAv8-64 provides APTable[1:0] control only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

D4.4.3 Access permissions for instruction execution

Execute-never controls determine whether instructions can be executed from a memory region. These controls are:

UXN, Unprivileged execute never

Descriptor bit[54], defined as UXN only for stage 1 of any translation regime that applies to EL0 and a higher Exception level.

PXN, Privileged execute never

Descriptor bit[53], used only for stage 1 of the any translation regime that applies to EL0 and a higher Exception level:

- For stage 1 of a translation regime that applies to only a single Exception level the descriptors define a PXN bit that is RES0, meaning it is ignored by hardware.
- For stage 2 of the Non-secure EL1&0 translation regime, descriptor bit[53] is RES0, meaning it is ignored by hardware.

XN, Execute never

Descriptor bit[54], defined as XN for:

- Stage 1 of any translation regime that applies to only a single Exception level.
- Stage 2 of the EL1&0 translation regime.

Note

In ARMv8.0, the only translation regime that applies to EL0 and a higher Exception level is the EL1&0 translation regime.

Each of these fields is set to 1 to indicate that instructions cannot be executed from the target memory region. In addition:

- For a translation regime that applies to EL0 and a higher Exception level, if the value of the AP[2:1] bits is 0b01, permitting write access from EL0, then the PXN bit is treated as if it has the value 1, regardless of its actual value.
- In the Non-secure EL1&0 translation regime, a region is execute-never if the value of the applicable execute-never field is 1 in one or both of:
 - The stage 1 translation table descriptor.
 - The stage 2 translation table descriptor.
- For each translation regime, if the value of the corresponding SCTL_R_EL_x.WXN bit is 1 then any memory region that is writable is treated as XN, regardless of the value of the corresponding UXN, XN, or PXN bit. For more information see [Preventing execution from writable locations on page D4-1790](#).
- The SCR_EL3.SIF bit prevents execution in Secure state of any instruction fetched from Non-secure memory, see [Restriction on Secure instruction fetch on page D4-1791](#).

The execute-never controls apply to speculative instruction fetching, meaning speculative instruction fetch from a memory region that is execute-never at the current Exception level is prohibited.

———— **Note** —————

- Although the execute-never controls apply to speculative fetching, on a speculative instruction fetch from an execute-never location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an execute-never location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as execute-never, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as execute-never. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
- When no stage of address translation for the translation regime is enabled, memory regions cannot have UXN, XN, or PXN attributes assigned. [Behavior of instruction fetches when all associated stages of translation are disabled on page D4-1768](#) describes how disabling all stages of address translation affects instruction fetching.

The following subsections describe the data access permission controls:

- [Stage 1 instruction access and execution permissions](#).
- [Stage 2 instruction execution permissions on page D4-1789](#).
- [Hierarchical control of instruction fetching on page D4-1789](#).
- [Preventing execution from writable locations on page D4-1790](#).
- [Restriction on Secure instruction fetch on page D4-1791](#).

Stage 1 instruction access and execution permissions

Table D4-33 on page D4-1788 and Table D4-34 on page D4-1789 include the AP[2:1] read and write permissions shown in Table D4-29 on page D4-1784 and Table D4-30 on page D4-1785. These permissions are shown as:

- R** Indicates Read permission granted.
- W** Indicates Write permission granted.

Table D4-33 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to EL0 and a higher Exception level.

Table D4-33 Stage 1 access permissions for instruction execution for a translation regime that applies to EL0 and a higher Exception level

| UXN | PXN | AP[2:1] | SCTLR_ELx.WXN ^a | Access from higher Exception level | Access from EL0 | |
|-----|-----|---------|----------------------------|------------------------------------|-----------------------------------|----------------------|
| 0 | 0 | 00 | 0 | R, W, Executable | Executable | |
| | | | 1 | R, W, Not executable ^b | Executable | |
| | | 01 | 0 | R, W, Not executable ^c | R, W, Executable | |
| | | | 1 | R, W, Not executable | R, W, Not executable ^d | |
| | | 10 | x | R, Executable | Executable | |
| | | 11 | x | R, Executable | R, Executable | |
| 0 | 1 | 00 | x | R, W, Not executable | Executable | |
| | | | 0 | R, W, Not executable | R, W, Executable | |
| | | 01 | 1 | R, W, Not executable | R, W, Not executable ^d | |
| | | | x | R, Not executable | Executable | |
| | | 11 | x | R, Not executable | R, Executable | |
| 1 | 0 | 00 | 0 | R, W, Executable | Not executable | |
| | | | 1 | R, W, Not executable ^b | Not executable | |
| | | 01 | x | R, W, Not executable ^c | R, W, Not executable | |
| | | 10 | x | R, Executable | Not executable | |
| | | 11 | x | R, Executable | R, Not executable | |
| | 1 | 1 | 00 | x | R, W, Not executable | Not executable |
| | | | | x | R, W, Not executable | R, W, Not executable |
| | | | 01 | x | R, Not executable | Not executable |
| | | | | x | R, Not executable | R, Not executable |

- a. Where ELx is the higher Exception level to which the translation regime applies.
- b. Not executable because of SCTLR_ELx.WXN control, because region is writable at ELx.
- c. Not executable, because AArch64 execution treats all regions writable at EL0 as being PXN.
- d. Not executable because of SCTLR_ELx.WXN control, because region is writable at EL0.

Table D4-34 shows the stage 1 access permissions for instruction execution when using a translation regime that applies to only a single Exception level.

Table D4-34 Access permissions for instruction execution for a translation regime that applies to only a single Exception level

| XN | AP[2] | SCTLR_ELx.WXN ^a | Access permission |
|----|-------|----------------------------|-----------------------------------|
| 0 | 0 | 0 | R, W, Executable |
| | | 1 | R, W, Not executable ^b |
| | 1 | x | R, Executable |
| 1 | 0 | x | R, W, Not executable |
| | 1 | x | R, Not executable |

- a. Where ELx is the higher Exception level to which the translation regime applies.
b. Not executable because of the SCTLR_ELx.WXN control, because region is writable at ELx.

Note

The Access permissions for an AArch64 translation regime that applies to only a single Exception level are consistent with the following fields in the translation table entries being treated as shown:

- AP treated as RES1.
- APTable[0] treated as RES0.
- PXN treated as RES0.
- PXNTable treated as RES0.

Stage 2 instruction execution permissions

For the Non-secure EL1&0 stage 2 translation, the XN bit in the stage 2 translation table descriptors controls the execution permission, and this control is completely independent of the S2AP access permissions.

Table D4-35 Access permissions for instruction execution for stage 2 of the Non-secure EL1&0 translation regime,

| XN | Access from Non-secure EL1or Non-secure EL0 |
|----|---|
| 0 | Executable |
| 1 | Not executable |

The stage 2 XN access permissions make no distinction between Non-secure accesses from EL1 and Non-secure accesses from EL0. However, when both stages of address translation are enabled, these permissions are combined with the stage 1 access permissions defined at stage 1 of the translation, see [Combining the stage 1 and stage 2 instruction execution permissions on page D4-1798](#).

Hierarchical control of instruction fetching

The VMSAv8-64 translation table format includes mechanisms by which entries at one level of translation table lookup can set limits on the permitted entries at subsequent levels of lookup. This subsection describes how these controls apply to the instruction fetching controls.

Note

Similar hierarchical controls apply to data accesses, see [Hierarchical control of data access permissions on page D4-1785](#).

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- [UXNTable](#) or [XNTable](#) restricts the execute-never control:
 - When the value of the [XNTable](#) bit is 1, the [XN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
 - When the value of the [UXNTable](#) bit is 1, the [UXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of its actual value.
 - When the value of a [UXNTable](#) or [XNTable](#) bit is 0 the bit has no effect.
- For a translation regime that applies to EL0 and a higher Exception level, [PXNTable](#) restricts the [PXN](#) control:
 - When the value of [PXNTable](#) is 1, the [PXN](#) bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
 - When the value of [PXNTable](#) is 0 it has no effect.

Note

The [UXNTable](#), [XNTable](#), and [PXNTable](#) settings are combined with the [UXN](#), [XN](#), and [PXN](#) bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The [UXNTable](#), [XNTable](#), and [PXNTable](#) controls are provided only for stage 1 translations. The corresponding bits are RES0 in the stage 2 translation table descriptors.

The effect of [UXNTable](#), [XNTable](#), or [PXNTable](#) applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to [UXNTable](#), [XNTable](#), or [PXNTable](#) requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Preventing execution from writable locations

ARMv8 provides control bits that, when corresponding stage 1 address translation is enabled, force writable memory to be treated as [UXN](#), [PXN](#), or [XN](#), regardless of the value of the [UXN](#), [PXN](#), or [XN](#) bit:

- For a translation regime that applies to EL0 and a higher Exception value, when the value of the applicable [SCTLR_ELx.WXN](#) field is 1:
 - All regions that are writable from EL0 at stage 1 of the address translation are treated as [UXN](#).
 - All regions that are writable from EL1 at stage 1 of the address translation are treated as [PXN](#).
- For a translation regime that applies to only a single Exception level, when the value of the applicable [SCTLR_ELx.WXN](#) field is 1, all regions that are writable at stage 1 of the address translation are treated as [XN](#).

Note

- The [SCTLR_ELx.WXN](#) controls are intended to be used in systems with very high security requirements.
 - Setting a [WXN](#) bit to 1 changes the interpretation of the translation table entry, overriding a zero value of a [UXN](#), [XN](#), or [PXN](#) field. It does not cause any change to the translation table entry.
-

For any given virtual machine, ARM expects WXN to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. This means that any change of these fields without a corresponding change of VMID might require synchronization and TLB invalidation, as described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1815.

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, SCR_EL3.SIF. When the value of this bit is 1, and execution is using the EL3 translation regime or the Secure EL1 translation regime, any attempt to execute an instruction fetched from Non-secure physical memory causes a Permission fault. TLB entries might reflect the value of this bit, and therefore any change to the value of this bit requires synchronization and TLB invalidation, as described in *TLB maintenance requirements and the TLB maintenance instructions* on page D4-1815.

D4.4.4 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0.

The AF bit in the translation table descriptors is the Access flag.

In ARMv8.0, the Access flag is managed by software as described in *Software management of the Access flag*.

Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of Access flag is 0.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

———— Note —————

If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

D4.5 Memory region attributes

The memory region attribute fields control the memory type, accesses to the caches, and whether the memory region is Shareable and therefore is coherent. This section also describes some additional translation table fields, that this manual groups with the memory region attributes.

In the EL1&0 translation regime, each enabled stage of address translation assigns memory region attributes, as described in this section. When both stages of translation are enabled, [Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime on page D4-1797](#) describes how the assignments from the two stages are combined.

———— Note —————

In a virtualization implementation, a hypervisor, executing at EL2, might usefully:

- Reduce the permitted cacheability of a region.
- Increase the required shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

The following sections describe these attributes:

- [The stage 1 memory region attributes.](#)
- [The stage 2 memory region attributes, EL1&0 translation regime on page D4-1794.](#)
- [Other fields in the VMSAv8-64 translation table format descriptors on page D4-1795.](#)

———— Note —————

This section describes the memory region attributes for each of the translation regimes, and for each stage of translation in the Non-secure EL1&0 translation regime.

A translation applies to memory accesses from either:

- Only a single Exception level, for example the EL3 translation regime.
- EL0 and one higher Exception level, for example the EL1&0 translation regime.

In general, attribute assignment is simpler in a regime that applies to only a single Exception level, and in these regimes behavior is consistent with fields in the translation tables being treated as follows:

- [AP\[1\]](#) is RES1, meaning the PE ignores the value of the bit and behaves as if it is 1.
- [APTable\[0\]](#) is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
- The [PXN](#) field is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.
- The [PXNTable](#) bit is RES0, meaning the PE ignores the value of the bit and behaves as if it is 0.

D4.5.1 The stage 1 memory region attributes

The description of the memory region attributes in a translation descriptor divides into:

Memory type and Cacheability

These are described indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description. [Stage 1 memory region type and Cacheability attributes](#) describes this encoding.

Shareability The SH[1:0] field in the translation table descriptor encodes shareability information. [Stage 1 Shareability attribute, for Normal memory on page D4-1793](#) describes this encoding.

Stage 1 memory region type and Cacheability attributes

In the VMSAv8-64 translation table format, the AttrIdx[2:0] field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field in the [MAIR_ELx](#) that specifies the attributes for the corresponding memory region. The required field is Attr_n, where $n = \text{AttrIdx}[2:0]$. For more information about AttrIdx[2:0] see [Attribute fields in stage 1 VMSAv8-64 Block and Page descriptors on page D4-1779](#)

———— **Note** ————

Each MAIR_ELx is a 64-bit register that is architecturally mapped to a pair of AArch32 registers. See the MAIR_ELx register descriptions for more information.

Each MAIR_ELx.Attrn field defines, for the corresponding memory region:

- The memory type, Device or Normal.
- For Device memory, the Device memory type, one of:
 - Device-nGnRnE.
 - Device-nGnRE.
 - Device-nGRE.
 - Device-GRE.
- For Normal memory:
 - The inner and outer cacheability, Non-cacheable, Write-Through, or Write-Back
 - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *No Allocate*, and the Transient allocation hints, if supported.

For more information about the memory type and attributes, see *Memory types and attributes* on page B2-94 and *Cacheability, cache allocation hints, and cache transient hints* on page D3-1695.

Stage 1 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-36 shows the encoding of this field.

Table D4-36 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

| SH[1:0] | Normal memory |
|---------|--|
| 00 | Non-shareable |
| 01 | Reserved, CONSTRAINED UNPREDICTABLE ^a |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492 for the permitted CONSTRAINED UNPREDICTABLE behavior.

———— **Note** ————

The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1799 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

D4.5.2 The stage 2 memory region attributes, EL1&0 translation regime

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- [Stage 2 memory region type and Cacheability attributes](#) describes how the MemAttr[3:0] field defines these attributes.
- The SH[1:0] field in the translation table descriptor encodes shareability information. [Stage 2 Shareability attribute, for Normal memory on page D4-1795](#) describes this encoding.

The following sections describe how, when both stages of address translation are enabled, the memory region attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- [Combining the stage 1 and stage 2 memory type attributes on page D4-1798](#).
- [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-1799](#).
- [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-1799](#).

Stage 2 memory region type and Cacheability attributes

[Table D4-37](#) shows how MemAttr[3:2] gives a top-level definition of the memory type, and of the Outer cacheability of a Normal memory region.

Table D4-37 VMSAv8-64 MemAttr[3:2] encoding, stage 2 translation

| MemAttr[3:2] | Memory type | Outer cacheability |
|--------------|--|-------------------------------|
| 00 | Device. MemAttr[1:0] encodes the Device memory type. | Not applicable |
| 01 | Normal. MemAttr[1:0] encodes the Inner Cacheability. | Outer Non-cacheable |
| 10 | | Outer Write-Through Cacheable |
| 11 | | Outer Write-Back Cacheable |

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2] == 0b00, indicating Device memory, [Table D4-38](#) shows the encoding of MemAttr[1:0].

Table D4-38 MemAttr[1:0] encoding for Device memory

| MemAttr[1:0] | Meaning when MemAttr[3:2] == 0b00 |
|--------------|-----------------------------------|
| 00 | Region is Device-nGnRnE memory |
| 01 | Region is Device-nGnRE memory |
| 10 | Region is Device-nGRE memory |
| 11 | Region is Device-GRE memory |

- When MemAttr[3:2] != 0b00, indicating Normal memory, [Table D4-39](#) shows the encoding of MemAttr[1:0].

Table D4-39 MemAttr[1:0] encoding for Normal memory

| MemAttr[1:0] | Meaning when MemAttr[3:2] != 0b00 |
|--------------|--|
| 00 | Reserved, CONSTRAINED UNPREDICTABLE ^a |

Table D4-39 MemAttr[1:0] encoding for Normal memory (continued)

| MemAttr[1:0] | Meaning when MemAttr[3:2] != 0b00 |
|--------------|-----------------------------------|
| 01 | Inner Non-cacheable |
| 10 | Inner Write-Through Cacheable |
| 11 | Inner Write-Back Cacheable |

a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492 for the permitted CONSTRAINED UNPREDICTABLE behavior.

Note

- The stage 2 translation does not assign any allocation hints.
- The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
 - MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
 - MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.

Stage 2 Shareability attribute, for Normal memory

When using the VMSAv8-64 translation table format, the SH[1:0] field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region. Table D4-40 shows the encoding of this field.

Table D4-40 SH[1:0] field encoding for Normal memory, VMSAv8-64 translation table format

| SH[1:0] | Normal memory |
|---------|--|
| 00 | Non-shareable |
| 01 | Reserved, CONSTRAINED UNPREDICTABLE ^a |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

a. See *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492 for the permitted CONSTRAINED UNPREDICTABLE behavior.

Note

- This encoding is the same as the shareability encoding described in *Stage 1 Shareability attribute, for Normal memory* on page D4-1793.
- The shareability field is only relevant if the memory is a Normal Cacheable memory type. All Device and Normal Non-cacheable memory regions are always treated as Outer Shareable, regardless of the translation table shareability attributes.

See *Combining the stage 1 and stage 2 shareability attributes for Normal memory* on page D4-1799 for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

D4.5.3 Other fields in the VMSAv8-64 translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors:

- *The Contiguous bit* on page D4-1796.
- *IGNORED fields* on page D4-1796.
- *Field reserved for software use* on page D4-1797.

The Contiguous bit

When the value of the Contiguous bit is 1, it indicates that the entry is one of a number of adjacent translation table entries that point to a *contiguous output address range*. The required number of adjacent entries depends on the current translation granule size, as follows:

4KB granule 16 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 16 entries must be aligned in the translation table. If accessing a full-sized 4KB translation table, this means that the top 5 of the 9 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

16KB granule This bit indicates that adjacent translation table entries point to contiguous output address range that has the same permissions and attributes. With the 16KB granule, the number of contiguous entries indicated by setting this bit to 1 depends on the lookup level of the translation table:

Level 2 lookup The bit indicates 32 contiguous entries, giving a 1GB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 6 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Level 3 lookup The bit indicates 128 contiguous entries, giving a 2MB block of memory. These entries must be aligned in the translation table. When accessing a full-sized 16KB translation table, this means the top 4 of the 11 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 128 translation table entries at the same translation table level.

64KB granule 32 adjacent translation table entries point to a contiguous output address range that has the same permissions and attributes. These 32 entries must be aligned in the translation table. If accessing a full-sized 64KB translation table, this means that the top 8 of the 13 input addresses bits that index the descriptor positions in the translation table are the same for all of the entries.

The contiguous output address range must be aligned to size of 32 translation table entries at the same translation table level.

Setting this bit to 1 means that the TLB can cache a single entry to cover the contiguous translation table entries.

This section defines the requirements for programming the Contiguous bit. [Possible translation table registers programming errors on page D4-1762](#) describes the effect of not meeting these requirements.

The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of the Contiguous bit.

TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues.

IGNORED fields

In the VMSAv8-64 translation table descriptors, the following fields are identified as IGNORED, meaning the architecture guarantees that a PE makes no use of these fields:

- In the stage 1 table descriptors, bits[58:52].
- In the stage 1 and stage 2 block and page descriptors, bits[63:59] and bits[58:55].

Of these fields:

- In the stage 1 and stage 2 block and page descriptors, bits[58:55] are reserved for software use, see [Field reserved for software use](#).
- In the stage 2 block and page descriptors, bits[63:60] are reserved for use by a System MMU control.

Field reserved for software use

The architecture reserves a 4-bit IGNORED field in the Block and Page table descriptors, bits[58:55], for software use. The definition of IGNORED means the architecture guarantees that hardware makes no use of this field.

———— Note —————

This means there is no need to invalidate the TLB if these bits are changed.

D4.5.4 Combining the stage 1 and stage 2 attributes, Non-secure EL1&0 translation regime

The Non-secure EL1&0 translation regime comprises two stage of translation, each of which can be enabled independently:

- Stage 1 translation is configured and controlled from EL1. When enabled, stage 1 translation can define access permissions independently for access from EL0 and for accesses from EL1.

Stage 1 MMU faults are taken to EL1.

- When stage 2 translation is enabled, the stage 2 access controls defined at EL2:
 - Affect only the Non-secure stage 1 access permissions settings.
 - Take no account of whether the accesses are at EL1 or EL0.
 - Permit software executing at EL2 to assign a write-only attribute to a memory region.

Stage 2 MMU faults are taken to EL2.

———— Note —————

In an implementation of virtualization, the attributes defined in the stage 2 translation tables mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The effects of the combination of attributes defined by the Hypervisor are functionally transparent to the Guest OS.

Combining the stage 1 and stage 2 data access permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [The AP\[2:1\] data access permissions, for stage 1 translations on page D4-1784](#).
- The stage 2 permissions described in [The S2AP data access permissions, Non-secure EL1&0 translation regime on page D4-1785](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an access is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an access is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.

3. If an access is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 instruction execution permissions

When both stages of translation are enabled, the following access permissions are combined:

- The stage 1 permissions described in [Stage 1 instruction access and execution permissions on page D4-1787](#).
- The stage 2 permissions described in [Stage 2 instruction execution permissions on page D4-1789](#).

The stage 1 and stage 2 permissions are combined as follows:

1. If an instruction fetch is not permitted by the stage 1 permissions, then it generates a Stage 1 Permission fault, regardless of the stage 2 permissions.
2. If an instruction fetch is permitted by the stage 1 permissions, but is not permitted by the stage 2 Permissions, then it generates a Stage 2 Permission fault.
3. If an instruction fetch is permitted by both the stage 1 permissions and the stage 2 permissions, then it does not generate a Permission fault.

Combining the stage 1 and stage 2 memory type attributes

[Table D4-41](#) shows the rules for combining the stage 1 and stage 2 memory type assignments.

Table D4-41 Combining the stage 1 and stage 2 memory type assignments

| Rule | If either stage of translation assigns: | The resultant memory type is: |
|--|---|-------------------------------|
| Device has precedence over Normal | Any Device memory type | A Device memory type |
| Non-Gathering has precedence over Gathering | A Device-nGxx memory type | A Device-nGxx memory type |
| Non-Reordering has precedence over Reordering | A Device-nGnRx memory type | A Device-nGnRx memory type |
| No Early write acknowledge has precedence over Early write acknowledge | The Device-nGnRnE memory type | The Device-nGnRnE memory type |

Regardless of any shareability attribute obtained as described in [Combining the stage 1 and stage 2 shareability attributes for Normal memory on page D4-1799](#):

- Any location for which the resultant memory type is any type of Device memory is always treated as Outer Shareable.
- Any location for which the resultant memory type is Normal Inner Non-cacheable, Outer Non-cacheable is always treated as Outer Shareable.

For information about how the cacheability attribute is obtained from the attributes assigned at each stage of translation see [Combining the stage 1 and stage 2 cacheability attributes for Normal memory on page D4-1799](#).

The combining of the memory type attributes from the two stages of translation means a translation table walk for stage 1 translation can be made to a type of Device memory. If this occurs then:

- If the value of [HCR_EL2.PTW](#) is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of [HCR_EL2.PTW](#) is 1, then the memory access generates a stage 2 Permission fault.

Combining the stage 1 and stage 2 cacheability attributes for Normal memory

For a Normal memory region, [Table D4-42](#) shows how the stage 1 and stage 2 cacheability assignments are combined. This combination applies, independently, for the Inner cacheability and Outer cacheability attributes.

Table D4-42 Combining the stage 1 and stage 2 cacheability assignments for Normal memory

| Assignment in stage 1 | Assignment in stage 2 | Resultant cacheability |
|---------------------------------------|---------------------------------------|-------------------------|
| Non-cacheable | Any | Non-cacheable |
| Any | Non-cacheable | Non-cacheable |
| Write-Through Cacheable | Write-Through or Write-Back Cacheable | Write-Through Cacheable |
| Write-Through or Write-Back Cacheable | Write-Through Cacheable | Write-Through Cacheable |
| Write-Back Cacheable | Write-Back Cacheable | Write-Back Cacheable |

Combining the stage 1 and stage 2 shareability attributes for Normal memory

A memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation, if either:

- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D4-1798](#), is any type of Device memory.
- The resultant memory type attribute, described in [Combining the stage 1 and stage 2 memory type attributes on page D4-1798](#), is Normal memory, and the resultant cacheability, described in [Combining the stage 1 and stage 2 cacheability attributes for Normal memory](#), is Inner Non-cacheable, Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal, that is not Inner Non-cacheable, Outer Non-cacheable, [Table D4-43](#) shows how the stage 1 and stage 2 shareability assignments are combined.

Table D4-43 Combining the stage 1 and stage 2 Shareability assignments for Normal memory^a

| Assignment in stage 1 | Assignment in stage 2 | Resultant shareability |
|-----------------------|-----------------------|------------------------|
| Outer Shareable | Any | Outer Shareable |
| Inner Shareable | Outer Shareable | Outer Shareable |
| Inner Shareable | Inner Shareable | Inner Shareable |
| Inner Shareable | Non-shareable | Inner Shareable |
| Non-shareable | Outer Shareable | Outer Shareable |
| Non-shareable | Inner Shareable | Inner Shareable |
| Non-shareable | Non-shareable | Non-shareable |

a. Applies only if the Normal memory is not Inner Non-cacheable, Outer Non-cacheable, see text.

D4.6 MMU faults

In a VMSAv8-64 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

| | |
|------------------------|--|
| Debug exception | An exception caused by the debug configuration, see Chapter D2 AArch64 Self-hosted Debug . |
| Alignment fault | An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Alignment support on page B2-76 . |
| MMU fault | An MMU fault is a fault generated by the fault checking sequence for the current translation regime. The remainder of this section describes MMU faults. |
| External abort | Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault. |

Collectively, these mechanisms are called *aborts*.

In AArch64 state MMU faults are synchronous exceptions that are reported as either:

- Data Aborts.
- Instruction Aborts

Note

Instruction Aborts report any synchronous memory abort on an instruction fetch.

External aborts can be reported synchronously or asynchronously. Asynchronous external aborts are reported using the SError interrupt. For more information, see [External aborts on page D3-1714](#).

An access that causes an abort is said to be aborted, and uses the *Fault Address Registers* (FARs) and *Exception Syndrome Registers* (ESRs) to record context information.

For more information, see [Synchronous exception types, routing and priorities on page D1-1547](#).

The Exception level that the MMU fault is taken to depends on the translation regime that generated the fault. The fault context saved in the appropriate `ESR_ELx`, where ELx is the Exception level that the fault is taken to, is dependent on whether:

- The MMU fault is due to an Instruction or Data Abort.
- The exception is taken from the same or a lower Exception level.

Software stepping, which is a debug feature, and a PC alignment fault exception are the only exceptions that are higher priority than an Instruction Abort. Only watchpoints are at a lower priority than Data Aborts in the exception priority hierarchy. For more information see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#).

The following sections describe the abort mechanisms:

- [Types of MMU faults on page D4-1801](#).
- [The MMU fault-checking sequence on page D4-1803](#).
- [AArch64 state prioritization of synchronous aborts from a single stage of address translation on page D4-1807](#).
- [Pseudocode description of the MMU faults on page D4-1809](#).

D4.6.1 Types of MMU faults

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page D4-1803. The following list includes all the types of exceptions that can occur:

- Alignment fault on a data access, see *Alignment support* on page B2-76.
- Permission fault, see *Permission fault*.
- Translation fault, see *Translation fault* on page D4-1802.
- Address size fault, see *Address size fault* on page D4-1802.
- Synchronous external abort on a translation table walk, see *External abort on a translation table walk* on page D4-1802.
- Access flag fault, see *Access flag fault* on page D4-1803.
- TLB conflict abort, see *TLB conflict aborts* on page D4-1814.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as Device.

The following subsections describe the MMU faults that are not described elsewhere in this Manual.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *About access permissions* on page D4-1783 for information about conditions that cause a Permission fault.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access.

This maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache maintenance instructions cannot generate Permission faults, except that:

- A stage 1 translation table walk performed as part of a cache maintenance instruction can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page D4-1806.
- When the value of `SCTLR_EL1.UCI` is 1, enabling EL0 execution of the `DC CVAU`, `DC CVAC`, `DC CIVAC`, and `IC IVAU` instructions:
 - Executing a `DC CVAU`, `DC CVAC`, or `DC CIVAC` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
 - It is IMPLEMENTATION DEFINED whether executing a `IC IVAU` instruction at EL0 to a location that does not have read permission at EL0 generates a Permission fault.
- A `DC IVAC` instruction requires write permission to the address it invalidates, otherwise it generates a Permission fault.

————— Note —————

- Execution of the `DCIMVAC` instruction in AArch32 state does not have this write permission requirement.
- When Non-secure EL1&0 stage 2 address translation is enabled, a `DC IVAC` instruction executed in Non-secure state operates as a `DC CIVAC` instruction, as described in *Effects of virtualization and security on the cache maintenance instructions* on page D3-1707.

The Data Cache Zero instruction, `DC ZVA`, operates as set of stores to each byte within the block being accessed, and therefore it generates a Permission fault if the translation system does not permit writes to these locations.

Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see [VMSAv8-64 translation table format descriptors on page D4-1774](#).

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a **TTBR**, or the **TTBR** range that it maps onto is disabled. In these cases the fault is reported as a level 0 Translation fault on the translation stage at which the mapping to a region described by a **TTBR** failed.

A data or unified cache maintenance by **VA** instruction can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by **VA** operation can generate a Translation fault.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Address size fault

An Address size fault can be generated at any level of lookup.

An Address size fault is generated if one of the following has nonzero address bits above the output address size, for the current stage of translation:

- The **TTBR** used for the translation.
- A translation table entry.
- The output address of the translation.

For an Address size fault generated because the **TTBR** used for the translation has nonzero address bits above the output address size, the reported fault code indicates a fault at level 0. Otherwise, the reported fault code indicates the lookup level at which the fault occurred.

A data or unified cache maintenance by **VA** instruction can generate an Address size fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by **VA** instruction can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

For more information on Address size faults, see [Output address size on page D4-1732](#).

External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
 - A synchronous Instruction Abort exception if the translation table walk is for an instruction fetch.
 - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using the SError interrupt exception.

Behavior of external aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in [Address translation instructions, functional group on page G4-4204](#) require translation table walks. An external abort can occur in the translation table walk. This is reported as follows:

- If the external abort is synchronous, using a synchronous Data Abort exception.
- If the external abort is asynchronous, using the SError interrupt exception.

For more information, see [Synchronous faults generated by address translation instructions on page D4-1772](#).

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if a translation table descriptor with the Access flag bit set to 0 is used.

For more information about the Access flag bit, see [VMSAv8-64 translation table format descriptors on page D4-1774](#).

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to execute any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance by VA instructions can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see [The Access flag on page D4-1791](#).

D4.6.2 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates an Instruction Abort.
- If an data memory access faults it generates a Data Abort.

MMU fault checking is performed for each stage of address translation.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see [About address translation and supported input address ranges on page D4-1728](#).

———— Note —————

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in [TLB conflict aborts on page D4-1814](#).

[Types of MMU faults on page D4-1801](#) describes the faults that an MMU fault-checking sequence can report.

[Figure D4-17 on page D4-1804](#) shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, if the translation is stage 1 of the Non-secure EL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

Figure D4-17 Fetching the descriptor in a VMSAv8-64 translation table walk

Figure D4-18 on page D4-1805 shows the full VMSA fault checking sequence, including the alignment check on the initial access.

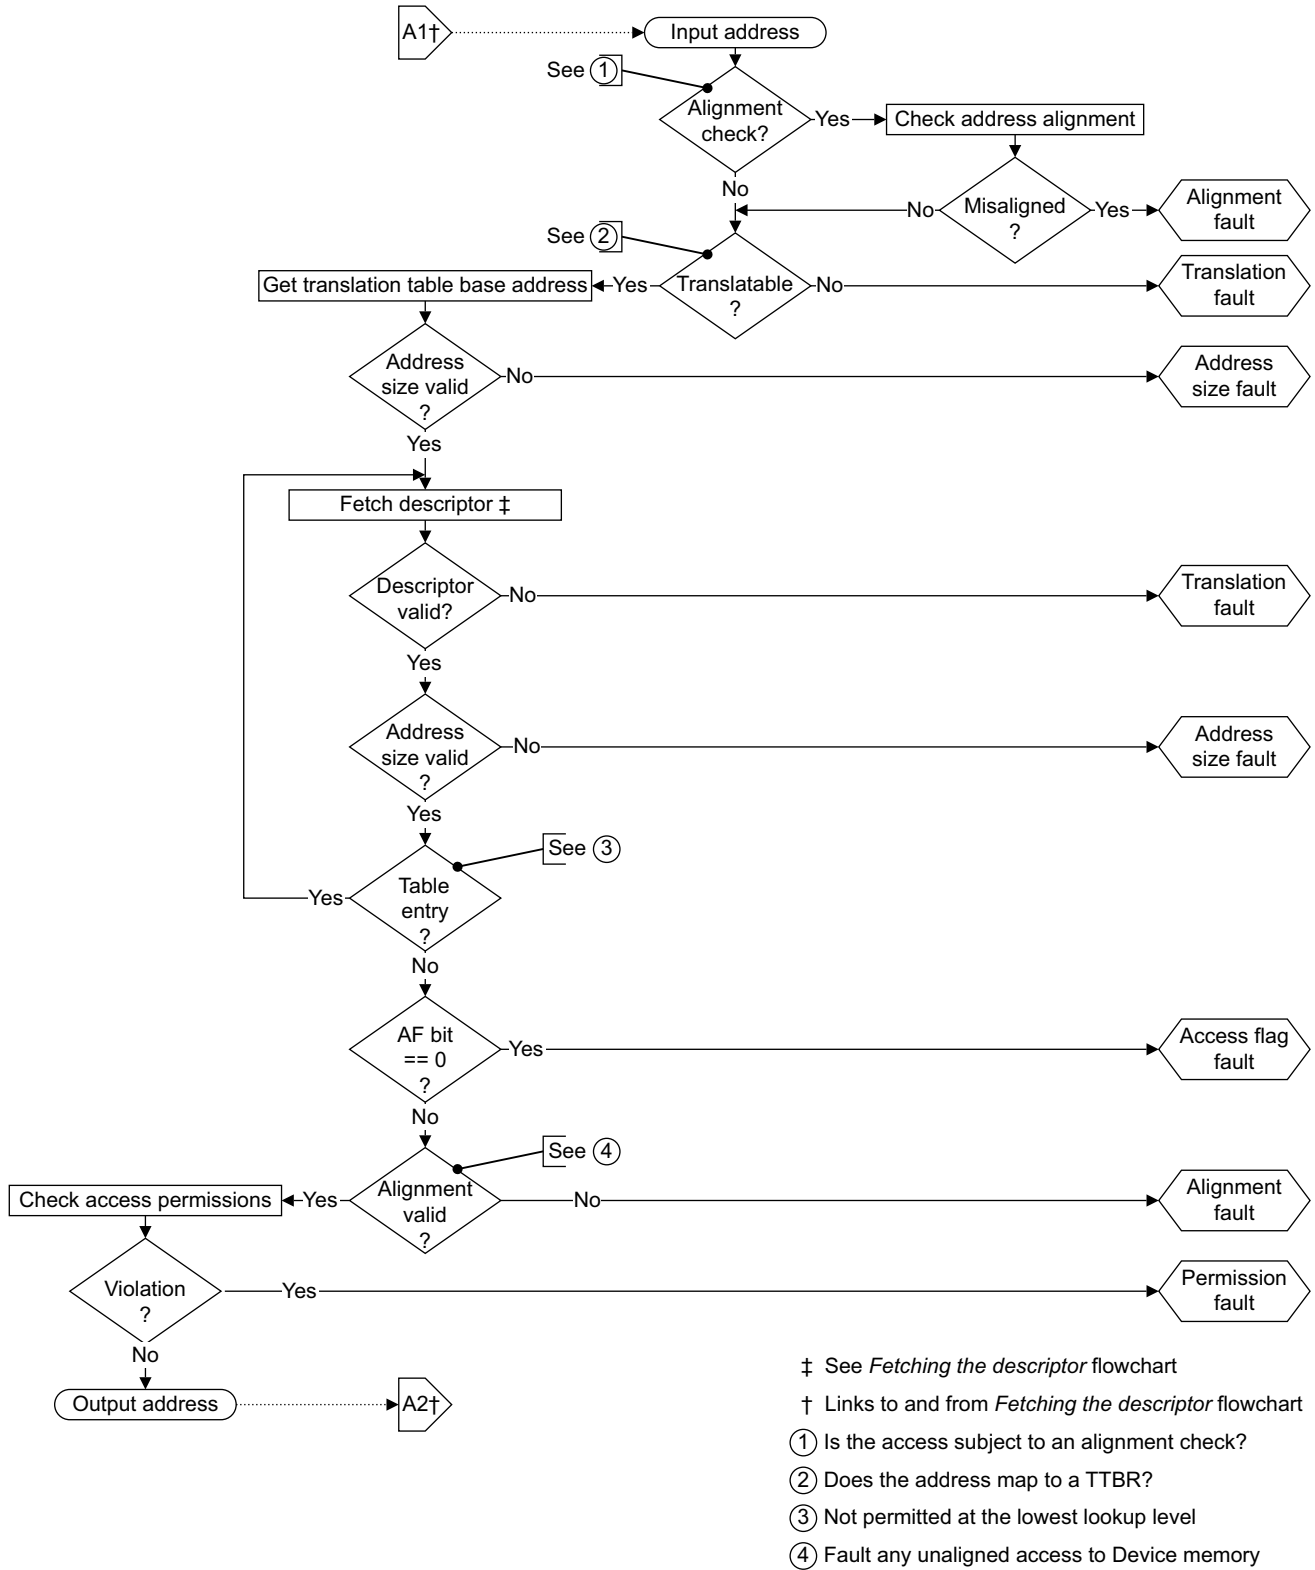

Figure D4-18 VMSAv8-64 fault checking sequence

Stage 2 fault on a stage 1 translation table walk

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If SCR_EL3.EA is set to 1, a synchronous external abort is taken to EL3. Otherwise, these faults are reported as stage 2 memory aborts. ESR_EL2.ISS[7] is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see *Use of the ESR_EL1, ESR_EL2, and ESR_EL3 on page D1-1523*.

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the Device attribute assigned on the stage 2 translation of the address accessed. When the HCR_EL2.PTW bit is set to 1, such an access generates a stage 2 Permission fault.

———— Note ————

On most systems, such a mapping to Device memory on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of HCR_EL2.PTW. Therefore, if HCR_EL2.PTW is changed without changing the current VMID, the TLBs must be invalidated before executing in Non-secure EL1 or Non-secure EL0 state. For more information see *Changing HCR_EL2.PTW on page D4-1828*.

A cache maintenance instruction executed at Non-secure EL1 can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

The level associated with MMU faults

For MMU faults, [Table D4-44](#) shows how the LL bits in the ESR_ELx.STATUS fields encode the lookup level associated with the fault.

Table D4-44 Use of LL bits to encode the lookup level at which the fault occurred

| LL bits | Meaning |
|---------|---|
| 00 | Level 0 of translation or translation table base register. |
| 01 | Level 1. |
| 10 | Level 2. |
| 11 | Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved. |

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see *Synchronous external aborts from address translation caching structures on page D4-1808*

D4.6.3 AArch64 state prioritization of synchronous aborts from a single stage of address translation

Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548 describes the prioritization of exceptions taken to an Exception level that is using AArch64. This section gives additional information about the prioritization of MMU faults from VMSAv8-64 translation regimes.

———— **Note** —————

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-64 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in *AArch32 state prioritization of synchronous aborts from a single stage of address translation* on page G4-4120.

For a single stage of translation in a VMSAv8-64 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur*. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults:
- For synchronous external aborts from translation table walks see also *Synchronous external aborts from address translation caching structures* on page D4-1808.

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring a **TTBR** that is disabled. This includes **VTCCR_EL2.SL0** being inconsistent with **VTCCR_EL2.T0SZ** or programmed to a reserved value.
3. Address size fault on a **TTBR** caused by either:
 - The check on **TCR_EL1.IPS**, **TCR_EL2.PS**, **TCR_EL3.PS**, or **VTCCR_EL2.PS**.
 - The **PA** being out of the range implemented.
4. *Second stage abort on a level 0 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the **PA** being out of the range implemented. This is second stage abort during a first stage translation table walk.*
5. Synchronous parity or ECC error on a level 0 lookup of a translation table walk.
6. Synchronous external abort on a level 0 lookup level of a translation table walk.
7. Translation fault on a level 0 translation table entry.
8. Address Size fault a level 0 lookup translation table entry caused by either:
 - The check on **TCR_EL1.IPS**, **TCR_EL2.PS**, **TCR_EL3.PS**, or **VTCCR_EL2.PS**.
 - The output address being out of the range implemented.
9. *Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the **PA** being out of the range implemented. This is second stage abort during a first stage translation table walk.*
10. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
11. Synchronous external abort on a level 1 lookup level of a translation table walk.
12. Translation fault on a level 1 translation table entry.
13. Address size fault on a level 1 lookup translation table entry caused by either:
 - The check on **TCR_EL1.IPS**, **TCR_EL2.PS**, **TCR_EL3.PS**, or **VTCCR_EL2.PS**.
 - The output address being out of the range implemented.

14. *Second stage abort on a level 2 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.*
15. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.
16. Synchronous external abort on a level 2 lookup level of a translation table walk.
17. Translation fault on a level 2 translation table entry.
18. Address size fault on a level 2 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
19. *Second stage abort on a level 3 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented. This is second stage abort during a first stage translation table walk.*
20. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.
21. Synchronous external abort on a level 3 lookup level of a translation table walk.
22. Translation fault on a level 3 translation table entry.
23. Address size fault on a level 3 lookup translation table entry caused by either:
 - The check on [TCR_EL1.IPS](#), [TCR_EL2.PS](#), [TCR_EL3.PS](#), or [VTCCR_EL2.PS](#).
 - The output address being out of the range implemented.
24. Access Flag fault.
25. Alignment fault caused by the memory type.
26. Permission fault.
27. *A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the PA being out of the range implemented.*
28. Synchronous parity or ECC error on the memory access.
29. Synchronous External Abort on the memory access.

Note

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

Synchronous external aborts from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous external aborts arising from the caching structure, including parity or ECC errors, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.

- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
 - The lowest-numbered level that could have given rise to the error.
 - Level 0 if the PE cannot determine any information about the level.

D4.6.4 Pseudocode description of the MMU faults

The following functions generate fault records that describe MMU faults:

- [AArch64.AccessFlagFault\(\)](#).
- [AArch64.AddressSizeFault\(\)](#).
- [AArch64.PermissionFault\(\)](#).
- [AArch64.TranslationFault\(\)](#).

Abort exceptions on page D3-1719 describes how fault records are used.

D4.7 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and the VMSA provides TLB maintenance instructions for the management of TLB contents.

———— **Note** ————

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

The following sections describe the architectural requirements for Translation Lookaside Buffers (TLBs) and their maintenance:

- [Use of ASIDs and VMIDs to reduce TLB maintenance requirements.](#)
- [About ARMv8 Translation Lookaside Buffers \(TLBs\) on page D4-1811.](#)
- [TLB maintenance requirements and the TLB maintenance instructions on page D4-1815.](#)

In these descriptions, TLB entries for a translation regime for a particular Exception level are *out of context* when executing at a higher Exception level.

D4.7.1 Use of ASIDs and VMIDs to reduce TLB maintenance requirements

To reduce the need for TLB maintenance on context switches, the lookups from some translation regimes can be associated with an ASID, or with an ASID and a VMID, as follows:

ASIDs For stage 1 translations that support two VA ranges the VMSA can distinguish between *Global pages* and *Process-specific pages*. The *Address Space Identifier (ASID)* identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

For these stage 1 translations, each of `TTBR0_ELx` and `TTBR1_ELx` has a valid ASID field, and `TCR_ELx.A1` determines which of these holds the current ASID.

———— **Note** ————

The selected ASID applies regardless of which set of translation tables are used. For example, when the value of `TCR_ELx.A1` is 0, any translation table lookup using this stage of translation is associated with the ASID from `TTBR0_ELx.ASID`, regardless of whether the translation lookup uses `TTBR0_ELx` or `TTBR1_ELx`.

See also [ASID size on page D4-1811](#) and [Global and process-specific translation table entries on page D4-1812](#).

For a symmetric multiprocessor cluster where a single operating system is running on the set of processing elements, the ARM architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all processing elements in the system.

VMIDs For the Non-secure EL1&0 translation regime, the *virtual machine identifier (VMID)* identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs.

`VTTBR_EL2.VMID` holds the current VMID.

ASID size

In VMSAv8-64, the [ASID](#) size is an IMPLEMENTATION DEFINED choice of 8 bits or 16 bits, and [ID_AA64MMFR0_EL1.ASIDBits](#) identifies the supported size. When an implementation supports a 16-bit [ASID](#), [TCR_ELx.AS](#) selects whether the top 8 bits of the [ASID](#) are used. When the value of [TCR_ELx.AS](#) is 0, [ASID\[15:8\]](#):

- Are ignored by hardware for every purpose other than direct reads of [TTBR0_ELx.ASID](#) and [TTBR1_ELx.ASID](#).
- Are treated as if they are all zeros when used for allocating and matching entries in the TLB.

———— **Note** —————

VMSAv8-32 uses an 8-bit [ASID](#). For backwards compatibility, when executing using translations controlled from an Exception level that is using AArch32, the [ASID](#) size remains at 8 bits. If the implementation supports 16-bit [ASIDs](#), the 8-bit [ASID](#) used is zero-extended to 16 bits.

D4.7.2 About ARMv8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement for every memory access to perform a translation table walk in memory. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in a TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

———— **Note** —————

A TLB can hold a translation table entry that does not itself generate a Translation fault but that points to a subsequent table in the translation table walk. This is referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not have been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- [Global and process-specific translation table entries on page D4-1812.](#)
- [TLB matching on page D4-1812.](#)
- [TLB behavior at reset on page D4-1813.](#)
- [TLB lockdown on page D4-1813.](#)
- [TLB conflict aborts on page D4-1814.](#)

See also [TLB maintenance requirements and the TLB maintenance instructions on page D4-1815.](#)

Global and process-specific translation table entries

In a VMSA implementation, system software can divide the virtual memory map used by a stage of translation that supports two VA ranges into global and non-global regions, indicated by the nG bit in the translation table descriptors:

nG == 0 The translation is global, meaning the region is available for all processes.

nG == 1 The translation is non-global, or process-specific, meaning it relates to the current [ASID](#), as defined by:

- [TTBR0_ELx.ASID](#), if the value of [TCR_ELx.A1](#) is 0.
- [TTBR1_ELx.ASID](#), if the value of [TCR_ELx.A1](#) is 01.

As indicated by the nG field definitions, each non-global region has an associated [ASID](#). These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

Note

- The selected [ASID](#) applies to the translation of any address for which the value of the nG bit is 1, regardless of whether the address is translated based on [TTBR0_EL1](#) or on [TTBR1_EL1](#).
- In ARMv8.0, the only stage of translation that supports two VA ranges is stage 1 of the EL1&0 translation regime.

[ASIDs](#) are supported only by stage 1 translations that support two VA ranges. Stage 2 translations, and stage 1 translations that support only a single VA range do not support [ASIDs](#), and all descriptors in these regimes are treated as global.

In a translation regime that supports global and non-global translations, translation table entries from lookup levels other than the final level of lookup are treated as being non-global, regardless of the value of the nG bit.

When a PE is using the VMSAv8-64 translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see [Control of Secure or Non-secure memory access on page D4-1782](#).

TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in [TLB maintenance requirements and the TLB maintenance instructions on page D4-1815](#) can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular [ASID](#) and [VMID](#) are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in [Using break-before-make when updating translation table entries on page D4-1816](#) is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB conflict fault code, see [TLB conflict aborts on page D4-1814](#).
- Might lead to **CONSTRAINED UNPREDICTABLE** behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. For more information see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5480](#).

TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs. The architecture recognizes that an implementation might require caches, including TLBs, to maintain their contents over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see [Controlling address translation stages on page D4-1729](#).
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.
ARM recommends that if an invalidation routine is required for this purpose, the routine is based on the TLB maintenance instructions described in [TLB maintenance instructions on page D4-1817](#).

Similar rules apply to cache behavior, see [Behavior of caches at reset on page D3-1698](#).

TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- VMSAv8-64 does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that a region of the system instruction encoding space is reserved for IMPLEMENTATION DEFINED functions, see [Reserved encodings for IMPLEMENTATION DEFINED registers on page C5-291](#). An implementation might use some of these encodings to implement TLB lockdown functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

In an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in Non-secure EL1 or Non-secure EL0 state can be routed to either:

- Non-secure EL1, as a Data Abort exception.
- Non-secure EL2, as a Hyp Trap exception.

For more information, see [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1577](#).

TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

———— **Note** —————

An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by the architecture has not been performed.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort:

- On an instruction fetch is reported as an Instruction abort, see [ISS encoding for an exception from an Instruction Abort on page D7-1953](#).
- On a data access is reported as a Data abort, see [ISS encoding for an exception from a Data Abort on page D7-1955](#).

ARMv8 defines the fault status encoding of 0b110000 for TLB conflict aborts. On a TLB conflict abort, the returned syndrome includes the address that generated the fault. That is, it includes the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

———— **Note** —————

A stage 2 abort cannot be generated if stage 2 of the Non-secure EL1&0 translation regime is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of a TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort is generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5480](#). The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Exception level.

D4.8 TLB maintenance requirements and the TLB maintenance instructions

Translation Lookaside Buffers (TLBs) are an implementation mechanism that caches translations or translation table entries. The ARM architecture does not specify the form of any TLB structures, but defines the mechanisms by which TLBs can be maintained. The following sections describe the VMSA TLB maintenance instructions:

- [General TLB maintenance requirements](#).
- [TLB maintenance instructions on page D4-1817](#).

See also:

- [Maintenance requirements on changing System register values on page D4-1828](#).
- [Atomicity of register changes on changing virtual machine on page D4-1735](#).

D4.8.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures to ensure that changes to the translation tables are reflected correctly in those TLB caching structures.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault, provided that the entry does not, itself, cause a Translation fault, an Address size fault, or an Access Flag fault. This means that the entries that can be cached include:

- Entries in translation tables that point to subsequent tables to be used in that stage of translation.
- Stage 2 translation table entries used as part of a stage 1 translation table walk
- Stage 2 translation table entries used to translate the output address of the stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are used during a translation table walk and that are distinct from the data caches in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction of the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries, and in particular for translation regimes that involve two stages of translation, it is recognized that such caching structures might contain:

- Entries containing information from stage 1 translation table entries, at any level of the translation table walk.
- Entries containing information from stage 2 translation table entries, at any level of the translation table walk.
- Entries that combine information from stage 1 and stage 2 translation table entries, at any level of the translation table walk.

———— **Note** —————

For the purpose of TLB maintenance, the term *TLB entry* denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entries in caching structures that include any stage 1 information that are used to translate the address being invalidated.

———— **Note** —————

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
- As stated in [Global and process-specific translation table entries on page D4-1812](#), translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their **ASID**, regardless of whether the final level is global. This means that TLB invalidations that involve the **ASID** require the **ASID** to match such entries to perform the required invalidation.

- Required to apply to stage 2 entries only, then:
 - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
 - It must apply to caching structures that contain information only from stage 2 translation table entries.
- Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Whenever translation tables entries associated with a particular **VMID** or **ASID** are changed, the corresponding entries must be invalidated from the TLB to ensure that these changes are visible to subsequent execution, including speculative execution, that uses the changed translation table entries.

Some System register field descriptions state that the effect of the field is permitted to be cached in a TLB. This means that all TLB entries that might be affected by a change of the field must be invalidated whenever that field is changed, to ensure that the effect of the change of that control field is visible to subsequent execution, including speculative execution, that uses that control field. This invalidation is required in addition to, and after, the normal synchronization of the System registers described in [Synchronization requirements for AArch64 System registers on page D7-1889](#), and applies to any stage of address translation that is implemented for the translation regime, and **VMID** if appropriate, that is affected by that control field. A control field that is permitted to be cached in a TLB requires this maintenance even when all stages of address translation are disabled.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see [Cache maintenance requirement created by changing translation table attributes on page D4-1832](#).

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access Flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB invalidation.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see [Using break-before-make when updating translation table entries](#).

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the exclusive monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entry and the new translation table entry is writable.
- A change to the size of block used by the translation system. This applies both:
 - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
 - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

D4.8.2 TLB maintenance instructions

The architecture defines TLB maintenance instructions, that provide the following:

- Invalidate all entries in the TLB.
- Invalidate a single TLB entry by [ASID](#) for a non-global entry.
- Invalidate all TLB entries that match a specified [ASID](#).
- Invalidate all TLB entries that match a specified [VA](#), regardless of the [ASID](#).

Each instruction can be specified as applying only to the PE that executes the instruction, or as applying to all PEs in the same Inner Shareable shareability domain as the PE that executes the instruction.

The following subsections describe these instructions:

- [TLB maintenance instruction syntax](#).
- [Operation of the TLB maintenance instructions on page D4-1819](#).
- [Scope of the A64 TLB maintenance instructions on page D4-1820](#).
- [Invalidation of TLB entries from stage 2 translations on page D4-1823](#).
- [Broadcast TLB maintenance between AArch32 and AArch64 on page D4-1824](#).
- [Broadcast TLB maintenance with different translation granule sizes on page D4-1825](#).
- [Ordering and completion of TLB maintenance instructions on page D4-1826](#).
- [TLB maintenance in the event of TLB conflict on page D4-1826](#).
- [The interaction of TLB lockdown with TLB maintenance instructions on page D4-1827](#).

[TLB maintenance instructions on page C5-278](#) describes the encoding of the TLB maintenance instructions.

TLB maintenance instruction syntax

The A64 syntax for TLB maintenance instructions is:

```
TLBI <operation>{, <Xt>}
```

Where:

<operation> Is one of ALLE1, ALLE2, ALLE3, ALLE1IS, ALLE2IS, ALLE3IS, VMALLE1, VMALLE1IS, VMALLS12E1, VMALLS12E1IS, ASIDE1, ASIDE1IS, VA{L}E1, VA{L}E2, VA{L}E3, VA{L}E1IS, VA{L}E2IS, VA{L}E3IS, VAA{L}E1, VAA{L}E1IS, IPAS2{L}E1, or IPAS2{L}E1IS.

<operation> has a structure of <type><level>{IS} where:

<type> Is one of:

ALL All translations used at <level>.

For the scope of ALL instructions see [ALL on page D4-1820](#).

The ALL instructions are valid for all values of <level>.

VMALL All stage 1 translations used at <level> with the current [VMID](#), if appropriate.

For the scope of the VMALL instructions see [VMALL on page D4-1820](#).

The VMALL instructions are valid only when `level == E1`.

- VMALLS12** All stage 1 and stage 2 translations used at EL1 with the current **VMID**, if appropriate.
For the scope of the **VMALLS12** instructions see [VMALLS12 on page D4-1821](#).
The **VMALLS12** instructions are valid only when `level == E1`.
- ASID** All translations used at EL1 with the supplied **ASID**.
For the scope of the **ASID** instructions see [ASID on page D4-1821](#).
The **ASID** instructions are valid only when `level == E1`.
- VA{L}** Translations used at `<level>` for the specified address and, if appropriate, the specified **ASID**.
For the scope of the **VA** instructions see [VA on page D4-1821](#). For the scope of the **VAL** instructions see [VAL on page D4-1821](#).
The **VA{L}** instructions are valid for all values of `<level>`.
- VAA{L}** Translations used at `<level>` for the specified address, for all **ASID** values, if appropriate.
For the scope of the **VAA** instructions see [VAA on page D4-1822](#). For the scope of the **VAAL** instructions see [VAAL on page D4-1822](#).
The **VAA{L}** instructions are valid only when `level == E1`.
- IPAS2{L}** Translations used at `<level>` for the specified **IPA** that are held in stage 2 only caching structures.
For the scope of the **IPAS2** instructions see [IPAS2 on page D4-1822](#). For the scope of the **IPAS2L** instructions see [IPAS2L on page D4-1822](#).
The **IPAS2{L}** instructions are valid only when `level == E1`.

In the **VA{L}**, **VAA{L}**, and **IPAS2{L}** types:

- L** An optional parameter that indicates that the invalidation only applies to caching of entries returned from the final lookup level of the translation table walk.

`<level>` Defines the Exception level of the translation regime that the invalidation applies to. Is one of:

- E1** EL1.
E2 EL2.
E3 EL3.

An instruction that applies to the translation regime of an Exception level higher than the Exception level at which the instruction is executed is **UNDEFINED**.

TLBI ALLE1{IS}, **TLBI IPAS2{L}E1{IS}** and **TLBI VMALLS12E1{IS}** are **UNDEFINED** at EL1.

———— **Note** —————

All TLB maintenance instructions are **UNDEFINED** at ELO.

- IS** When present, it indicates that the function applies to all TLBs in the Inner Shareable shareability domain.

`<Xt>` Passes one or both of an address and an **ASID** as an argument, where required. `<Xt>` is required for the **TLBI ASID**, **TLBI VA{L}**, **TLBI VAA{L}**, and **TLBI IPAS2{L}** instructions.

If EL2 is not implemented, the **TLBI VA{L}E2**, **TLBI VA{L}E2IS**, **TLBI ALLE2**, and **TLBI ALLE2IS** instructions are **UNDEFINED**.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds a **VA**, an **ASID**, or both, use the following register argument format:

Bits[63:48] **ASID**. These bits are **RES0** if the instruction does not require an **ASID** argument.

Bits[47:44] **RES0**.

- Bits[43:0]** VA[55:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
- 4KB granule size** All bits are valid and used for the invalidation.
 - 16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
 - 64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

These bits are RES0 if the instruction does not require a VA argument.

For TLB maintenance instructions that take an address argument, hardware interprets VA[63:56] as each having the same value as VA[55].

If a TLB maintenance instruction targets a translation regime that is using AArch32, meaning the VA is only 32-bit, then software must treat VA[55:32] as RES0, and these bits are ignored when the instruction is executed.

If the implementation supports 16 bits of ASID then the upper 8 bits of the ASID are RES0 when the context being invalidated only uses 8 bits.

VMSAv8-64 TLB maintenance instructions that take a register argument that holds an IPA, use the following register argument format:

- Bits[63:36]** RES0.
- Bits[35:0]** IPA[47:12]. For an instruction that requires a VA argument, the treatment of the low-order bits of this field depends on the translation granule size, as follows:
- 4KB granule size** All bits are valid and used for the invalidation.
 - 16KB granule size** Bits[1:0] RES0 and ignored when the instruction is executed, because IPA[13:12] have no effect on the operation of the instruction.
 - 64KB granule size** Bits[3:0] are RES0 and ignored when the instruction is executed, because IPA[15:12] have no effect on the operation of the instruction.

Operation of the TLB maintenance instructions

Any TLB maintenance instruction can affect any TLB entries that are not locked down.

The TLB maintenance instructions specify the Exception level of the translation regime to which they apply.

———— Note —————

Because there is no guarantee that an unlocked TLB entry remains in the cache, architecturally it is not possible to tell whether a TLB maintenance instruction has affected any TLB entries that were not specified by the instruction.

If a TLB maintenance instruction specifies a VA, and a data or instruction access to that VA would generate an MMU abort, the TLB maintenance instruction does not generate an abort. VAs for which a TLB maintenance instruction does not generate an abort include VAs that are not in the range of VAs that can be translated.

When EL3 is implemented:

- The TLB maintenance instructions that apply to the EL1&0 translation regime take account of the current Security state, as part of the address translation required for the TLB operation.
- SCR_EL3.NS modifies the effect of the TLB maintenance instructions as follows:
 - For instructions that apply to the EL1&0 translation regime, the SCR_EL3.NS bit identifies whether the maintenance instructions apply to the Secure or Non-secure EL1&0 translation regime.

———— Note —————

If EL3 is not implemented, then there is only a single EL1&0 translation regime.

- For instructions that apply to the EL2 translation regime, the SCR_EL3.NS bit must be 1 or the instruction is UNDEFINED.
- For instructions that apply to the EL3 translation regime, the SCR_EL3.NS bit has no effect.

Note

- An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.
- Previous versions of the ARM architecture included TLB maintenance instructions that operated only on instruction TLBs, or only on data TLBs. From the introduction of ARMv7, ARM deprecated any use of these instructions. In ARMv8:
 - AArch64 state does not include any of these instructions.
 - AArch32 state includes some of these instructions, but ARM deprecates their use.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, when a TLB maintenance instruction is executed, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

Note

The Contiguous bit does not affect the minimum size of entry that must be invalidated from the TLB

Scope of the A64 TLB maintenance instructions

The TLB invalidation instruction <type> affects the different possible cached entries in the TLB as follows:

ALL The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with the state specified by [SCR_EL3.NS](#).

For entries from the Non-secure EL1&0 translation regime, ALL applies to entries with any [VMID](#).

For entries from the EL1&0 translation regimes, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

Note

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any [ASID](#).

VMALL The invalidation applies to all cached copies of the stage 1 translation table entries, from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#).
- For the Non-secure EL1&0 translation regime, the current [VMID](#).

For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies to:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

Note

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any [ASID](#).

VMALL is valid only for EL1.

- VMALLS12 The invalidation applies to all cached copies of the stage 1 and stage 2 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
- The Security state specified by [SCR_EL3.NS](#).
 - For the Non-secure EL1&0 translation regime, the current [VMID](#).
- For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies to:
- All entries above the final level of lookup.
 - All entries at the final level of lookup.
- **Note** —————
- This means the invalidation applies to both:
- Global entries.
 - Non-global entries with any [ASID](#).
-
- VMALLS12 is valid only for EL1.
- If EL2 is not implemented, or if the TLBI VMALLS12 instruction is executed when the value of [SCR_EL3.NS](#) is 0, the instruction is not UNDEFINED but it has the same effect as TLBI VMALL. This is because there are no stage 2 translations to invalidate.
- ASID The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate any address at the specified Exception level, that would be used with all of:
- The Security state specified by [SCR_EL3.NS](#).
 - For the Non-secure EL1&0 translation regime, the current [VMID](#).
- For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies only if either:
- The entry is from a level of lookup above the final level and matches the specified [ASID](#).
 - The entry is a non-global entry from the final level of lookup and matches the specified [ASID](#).
- ASID is valid only for EL1.
- VA The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:
- The Security state specified by [SCR_EL3.NS](#).
 - For the Non-secure EL1&0 translation regime, the current [VMID](#).
- For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies only if one of the following applies:
- The entry is from a level of lookup above the final level and matches the specified [ASID](#).
 - The entry is a global entry from the final level of lookup.
 - The entry is a non-global entry from the final level of lookup that matches the specified [ASID](#).
- VAL The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level, that would be used with all of:
- The Security state specified by [SCR_EL3.NS](#).
 - For the Non-secure EL1&0 translation regime, the current [VMID](#).

For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies only if either:

- The entry is a global entry from the final level of lookup.
- The entry is a non-global entry from the final level of lookup that matches the specified [ASID](#).

VAA The invalidation applies to all cached copies of the stage 1 translation table entries from any level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#).
- For the Non-secure EL1&0 translation regime, the current [VMID](#).

For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies to all of:

- All entries above the final level of lookup.
- All entries at the final level of lookup.

———— **Note** —————

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any [ASID](#).

VAA The invalidation applies to all cached copies of the stage 1 translation table entry from the final level of the translation table walk required to translate the address specified in the invalidation instruction at the specified Exception level that would be used with all of:

- The Security state specified by [SCR_EL3.NS](#).
- For the Non-secure EL1&0 translation regime, the current [VMID](#).

For entries from the EL1&0 translation regimes that meet the other specified conditions, the invalidation applies to all entries at the final level of lookup.

———— **Note** —————

This means the invalidation applies to both:

- Global entries.
- Non-global entries with any [ASID](#).

IPAS2 The invalidation applies to all cached copies of the stage 2 translation table entries from any level of the translation table walk required to translate the specified [IPA](#), that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current [VMID](#).

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the [SCR_EL3.NS](#)==0, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2 instruction see [Invalidation of TLB entries from stage 2 translations on page D4-1823](#).

IPAS2L The invalidation applies to cached copies of the stage 2 translation table entry from the final level of the stage 2 translation table walk required to translate the specified [IPA](#), that both:

- Are held in TLB caching structures holding stage 2 only entries.
- Would be used with the current [VMID](#).

It is not required that this instruction invalidates TLB caching structures holding entries that combine stage 1 and stage 2 of the translation.

The only translation regime to which this instruction can apply is the Non-secure EL1&0 translation regime.

When executed with the `SCR_EL3.NS==0`, or in an implementation that does not implement EL2, this instruction is a NOP.

For more information about the architectural requirements for the IPAS2L instruction see [Invalidation of TLB entries from stage 2 translations](#).

The entries that the invalidations apply to are not affected by the state of any other control bits involved in the translation process. Therefore, the following is a non-exhaustive list of control bits that do not affect how a TLB maintenance instruction updates the TLB entries:

In AArch64 state

`SCTLR_EL1.M`, `SCTLR_EL2.M`, `SCTLR_EL3`.{M, RW}, `HCR_EL2`.{VM, RW},
`TCR_EL1`.{TG1, EPD1, T1SZ, TG0, EPD0, T0SZ, AS, A1}, `TCR_EL2`.{TG0, T0SZ},
`TCR_EL3`.{TG0, T0SZ}, `VTCR_EL2`.{SL0, T0SZ}, `TTBR0_EL1.ASID`, `TTBR1_EL1.ASID`.

In AArch32 state

`SCTLR.M`, `HCR.VM`, `TBCCR`.{EAE, PD1, PD0, N, EPD1, T1SZ, EPD0, T0SZ, A1},
`HTCR.T0SZ`, `VTCR`.{SL0, T0SZ}, `TTBR0.ASID`, `TTBR1.ASID`, `CONTEXTIDR.ASID`.

Note

- ARM expects most TLB maintenance performed by an operating system to occur to the last level entries of the stage 1 translation table walks, and the purpose of the address-based TLB invalidation instructions where the invalidation need only apply to caching of entries returned from the last level of translation table walk of stage 1 translation is to avoid unnecessary loss of the intermediate caching of the translation table entries. Similarly, for stage 2 translations ARM expects that most TLB maintenance performed by a hypervisor for a given Guest operation system will affect only the last level entries of the stage 2 translations. Therefore, similar capability is provided for instructions that invalidate single stage 2 entries.
- The architecture permits the invalidation of entries in TLB caching structures at any time, so for each of these instructions the definition is in terms of the minimum set of entries that must be invalidated from TLB caching structures, and an implementation might choose to invalidate more entries. In general, for best performance, ARM recommends not invalidating entries that are not required to be invalidated.
- Dependencies on the `VMID` for the Non-secure EL1&0 translation regime apply even when `HCR_EL2.VM` is set to 0. Because the architecture does not require the `VTTBR_EL2.VMID` field to be reset in hardware, the reset routine of each active PE must initialize `VTTBR_EL2.VMID[7:0]` to a common value such as 0, even if stage 2 translation is not in use.

Invalidation of TLB entries from stage 2 translations

The architectural requirements of the IPAS2 instruction are that:

1. The following code is sufficient to invalidate all cached copies of the stage 2 translation of the `IPA` held in `Xt` for the current `VMID`, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VMALLE1
```
2. The following code is sufficient to invalidate all cached copies of the stage 2 translations of the `IPA` held in `Xt` used to translate the `VA` (and the specified `ASID` when executing `TLBI VAE1`) held in `Xt2`, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VAE1, Xt2 ; or TLBI VAAE1, Xt2
```

- The following code is sufficient to invalidate all cached copies of the stage 2 translations of the **IPA** held in **Xt** used to translate the **IPA** produced by the last level of stage 1 translation table lookup for the **VA** (and **ASID** when executing **TLBI VALE1**) held in **Xt2**, with the corresponding requirement for the broadcast versions of the instructions:

```
TLBI IPAS2E1, Xt
DSB
TLBI VALE1, Xt2 ; or TLBI VAALE1, Xt2
```

———— **Note** ————

Depending on the invalidation required, software must use the entire sequence 1, 2, or 3, even when Non-secure EL1&0 stage 1 translation is disabled.

Equivalent architectural requirements apply to the **IPAS2L** instruction, except that the only TLB entries that must be invalidated by an **IPAS2L** instruction are those that come from the final level of the translation table lookup.

Broadcast TLB maintenance between AArch32 and AArch64

In most cases, a TLB maintenance instruction affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch64 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch32, provided that the address, qualify the scope of the **ASID** and **VMID** matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions on page D4-1820*.

———— **Note** ————

The requirement to match means that the invalidation only occurs on the PE that is using AArch32 if, for the PE that executed the TLB maintenance instruction at an Exception level that is using AArch64, both of the following apply:

- If **VA** matching is required, the **VA** is **0x0000FFFFFFFF** or lower of the memory space.
- If **ASID** matching is required and the PE is using a 16-bit **ASID**, then the top 8 bits of the **ASID** are zero.

Except for the cases identified here, a TLB maintenance instructions affecting the Inner Shareable shareability domain executed by a PE in an Exception level that is using AArch32 also affects any other PE in the same Inner Shareable domain that is executing at the same Exception level and is using AArch64, provided that the address, **ASID**, and **VMID** matching requirements of the original instruction are met, as specified in *Scope of the A64 TLB maintenance instructions on page D4-1820*. In addition, for the instruction executed in AArch32 state:

- For a **TLBIMVAAIS**, **TLBIMVAALIS**, **TLBIMVAHIS**, **TLBIMVAIS**, **TLBIMVALHIS**, or **TLBIMVALIS** instruction, the **VA** supplied as an argument is zero-extended.
- For a **TLBIIPAS2IS** or **TLBIIPAS2LIS** instruction, the **IPA** supplied as an argument is zero-extended.
- For a **TLBIASIDIS**, **TLBIMVAIS**, or **TLBIMVALIS** instruction, the **ASID** supplied as an argument is zero-extended if the PE executing in AArch64 state is using a 16-bit **ASID**.

The **VA** from the instruction executed in AArch32 state is zero-extended, and the **ASID** is zero-extended if the PE executing in AArch64 state is using a 16-bit **ASID**.

The exceptions to these general rules are as follows:

1. An ARMv7 PE in the same Inner Shareable domain is treated in the same way as an ARMv8 PE for which EL3 is using AArch32, except that if an ARMv8 PE issues a broadcast instruction that is not defined in ARMv7, then that instruction is not required to have an effect on the TLBs of the ARMv7 PE. The instructions that do not exist in ARMv7 include the following TLB maintenance instructions that ARMv8 adds to the T32 and A32 instruction sets:
 - The following instructions that operate on TLB entries for the final level of translation table walk for stage 1 translations:
TLBIMVALIS, TLBIMVAALIS, TLBIMVALHIS, TLBIMVAL, TLBIMVAAL, and TLBIMVALH.
 - The following instructions that operate by IPA on TLB entries for stage 2 translations:
TLBIIPAS2IS, TLBIIPAS2LIS, TLBIIPAS2, and TLBIIPAS2L.
2. The number of Exception levels in Secure state depends on whether EL3 is using AArch32 or EL3 is using AArch64. This means that, within the Inner Shareable domain, there might be PEs with different numbers of Exception levels in Secure state. Therefore, the following exceptions are made to the general rules:
 - If a PE with EL3 using AArch32 issues a broadcast AArch32 TLB maintenance instruction affecting Secure entries, and the Inner Shareable domain also contains PEs with EL3 using AArch64, then the architecture does not require that the broadcast AArch32 TLB maintenance instruction has any effect on either:
 - The EL3 translation regime of the PEs with EL3 using AArch64.
 - The Secure EL1 translation regime of the PEs with EL3 using AArch64, regardless of whether the Secure EL1 translation regime is using AArch64 or AArch32.
 - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting EL3 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32, then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.
 - If a PE with EL3 using AArch64 issues a broadcast AArch64 TLB maintenance instruction affecting Secure EL1 entries, and the Inner Shareable domain also contains PEs with EL3 using AArch32 then the architecture does not require that the broadcast AArch64 TLB maintenance instruction has any effect on the EL3 translation regime of the PEs with EL3 using AArch32.

Note

While the exceptions to the general rule mean the architecture does not require the specified TLB invalidations, the architecture also does not require that entries in the TLB remain in the TLB at any time, and so it is permissible that such broadcast instructions affect these translation regimes.

Broadcast TLB maintenance with different translation granule sizes

In the following cases, a broadcast TLB maintenance instruction is not required to perform any invalidation on the recipient PE:

- The TLB maintenance instruction specifying a VA and affecting the EL2 translation regime or the EL3 translation regime is broadcast from a PE using one translation granule size for that translation regime to a PE using a different translation granule size for that same translation regime
- The TLB maintenance instruction specifying a VA and affecting the EL1 translation regime is broadcast from a PE using one stage 1 translation granule size for that translation regime for a particular ASID (if applicable), VMID (if applicable), and Security state, to a PE where EL1 for the same ASID (if applicable), VMID (if applicable), and Security state, is using a different stage 1 translation granule size.
- The TLB maintenance instruction specifying a VA and affecting the Non-secure EL1 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular ASID (if applicable) and VMID, to a PE where EL1 for the same ASID (if applicable) and VMID is using a different stage 2 translation granule size.

- The TLB maintenance instruction specifying an [IPA](#) and affecting the Non-secure EL1 translation regime is broadcast from a PE using one stage 2 translation granule size for a particular [VMID](#) to a PE where EL1 for the same [VMID](#) is using a different stage 2 translation granule size.

Ordering and completion of TLB maintenance instructions

For AArch64 execution, a TLB maintenance instruction can be executed in any order relative to:

- Any load or store instruction, unless a DSB is executed between the load or store and the TLB maintenance instruction.

———— **Note** —————

In the ARM architecture, a translation table walk is considered to be a separate observer, and a store to translation tables can be observed by that separate observer at any time after the instruction has been executed, but is only guaranteed to be observable after the execution of a DSB instruction by the PE that executed the store to the translation tables.

- Another TLB maintenance instruction, unless a DSB is executed between the instructions.
- A data or instruction cache maintenance instruction, unless a DSB is executed between the instructions.

For AArch64 execution, the completion rules are:

- A TLB invalidate instruction is complete when all memory accesses using the TLB entries that have been invalidated have been observed by all observers, to the extent that those accesses must be observed. The shareability and cacheability of the accessed memory locations determine the extent to which the accesses must be observed.

———— **Note** —————

For TLB maintenance instructions that affect other PEs, the memory accesses from those PEs that used the TLB entries that have been invalidated are included in the set of memory accesses that must have been observed when the TLB maintenance instruction is complete.

After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be observed by those observers.

———— **Note** —————

This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

- A TLB maintenance instruction can complete at any time after it is issued, but is only guaranteed to be complete after the execution of DSB by the PE that executed the TLB maintenance instruction.
- The effects of a completed TLB maintenance instruction are only guaranteed to be visible on the PE that executed the instruction after the execution of a [Context synchronization event](#) by the PE that executed the TLB maintenance instruction.

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

TLB maintenance in the event of TLB conflict

In the event that multiple entries in the TLB are being used to translate a given address (which implies that an attempt to access the given address might give rise to a TLB Conflict abort), it is IMPLEMENTATION DEFINED as to the form of TLB maintenance operation that the software must perform in order to be guaranteed that all TLB entries

associated with the given address and translation regime have been invalidated. In all cases, an ALL or VMALL form of TLB maintenance operation that targets the given translation regime is guaranteed to remove all entries within that regime, even if there are multiple, conflicting TLB entries for any given address within that regime.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on a locked TLB entry of a TLB invalidate all operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the instruction operation must be implemented as one of the following options:
 - The operation has no effect on entries that are locked down.
 - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down.
Any such exceptions taken from Non-secure EL1 can be trapped to EL2, see [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page D1-1577](#).
- **Note** —————
- These options permit a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.
-
- The effect on a locked TLB entry of a TLB invalidate by VA or invalidate by ASID match operation that would invalidate that entry if the entry was not locked is IMPLEMENTATION DEFINED. However, the operation must implement one of the following options:
 - The locked entry is invalidated in the TLB.
 - The operation has no effect on any locked entry in the TLB. In the case of an invalidate single entry by VA, this means the PE treats the operation as a NOP.
 - The operation generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down.

The exception syndrome definitions include a fault code for cache and TLB lockdown faults, see [ESR_ELI, Exception Syndrome Register \(ELI\) on page D7-1930](#).

———— **Note** —————

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined operations. This minimizes the number of customized operations required.

In addition, an implementation that uses an abort mechanism for handling the effect of TLB maintenance instructions on entries that can be locked down but are not actually locked down must provide an IMPLEMENTATION DEFINED mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see [The interaction of cache lockdown with cache maintenance instructions on page D3-1712](#).

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of any TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

D4.8.3 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the **VMID** or **ASID** that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in System registers
ISB          ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that maintenance requirement applies to are:

- Any change to the **MAIR_EL1**, **MAIR_EL2**, or **MAIR_EL3** registers.
- Any change to the **AMAIR_EL1**, **AMAIR_EL2**, or **AMAIR_EL3** registers.
- Any change to **SCTLR_EL1.EE**, **SCTLR_EL2.EE**, or **SCTLR_EL3.EE**.
- Any change to **SCTLR_EL1.WXN**, **SCTLR_EL2.WXN**, or **SCTLR_EL3.WXN**.
- Any change to any of the **SCR_EL3**.{RW, SIF} bits.
- Any change to any of the **HCR_EL2**.{RW, DC, PTW, VM} bits. See also *Changing HCR_EL2.PTW*.
- Any changes to the registers that control address translation:
 - Any change to any of the **TCR_EL1**, **TCR_EL2**, **TCR_EL3**, or **VTCR_EL2** registers.
 - Any change to the **TTBR0_EL1**, **TTBR1_EL1**, **TTBR0_EL2**, **TTBR0_EL3**, or **VTTBR_EL2** registers.

Changing HCR_EL2.PTW

When the value of the Protected table walk bit, **HCR_EL2.PTW**, is 1, a stage 1 translation table access in the Non-secure EL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular **VMID** might hold entries that depend on the effect of **HCR_EL2.PTW**. Therefore, if the value of **HCR_EL2.PTW** is changed without a change to the **VMID** value, all TLB entries associated with the current **VMID** must be invalidated before executing software at Non-secure EL1 or EL0. If this is not done, behavior is **CONSTRAINED UNPREDICTABLE**, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5480*.

D4.9 Caches in a VMSAv8-64 implementation

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

In particular, maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and address translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- [Data and unified caches](#).
- [Instruction caches](#).

In addition, [Cache maintenance requirement created by changing translation table attributes on page D4-1832](#) describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see [Cache maintenance instructions on page D3-1703](#), that describes the cache maintenance instructions in the A64 instruction set.

D4.9.1 Data and unified caches

For data and unified caches, the use of address translation is entirely transparent to any data access other than as described in [Mismatched memory attributes on page B2-105](#).

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

D4.9.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- PIPT instruction caches.
- *Virtually-indexed, physically-tagged* (VIPT) instruction caches.
- ASID and VMID tagged *Virtually-indexed, virtually-tagged* (VIVT) instruction caches.

The `CTR_EL0.L1Ip` field identifies the form of the instruction caches.

The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of address translation transparent to the instruction cache:

- [PIPT instruction caches](#).
- [VIPT instruction caches](#).
- [ASID and VMID tagged VIVT instruction caches on page D4-1831](#).
- [The IIVIPT Extension on page D4-1831](#).

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or [ASID](#) and [VMID](#) tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches other than as described in [Mismatched memory attributes on page B2-105](#).

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IIVIPT Extension, see [The IIVIPT Extension on page D4-1831](#).

VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in [Mismatched memory attributes on page B2-105](#).

Note

Cache invalidation is the only cache maintenance that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the [VA](#) supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a [PA](#) from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IIVIPT Extension, see [The IIVIPT Extension on page D4-1831](#).

ASID and VMID tagged VIVT instruction caches

For **ASID** and **VMID** tagged VIVT instruction caches, if the instructions at any **VA** change, for a given translation regime and a given **ASID** and **VMID**, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a **VA** to a **PA**, if, as a result of the change to the translation, the instructions at the **VAs** change:

- For any translation regime other than the Non-secure EL1&0 translation regime, enabling or disabling stage 1 translations.
- For the Non-secure EL1&0 translation regime:
 - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of **VMID**.
 - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
 - Enabling or disabling stage 2 translations.
- Writing new mappings to the translation tables.
- Any change to the **TCR** or **TTBR** for the current translation regime, unless:
 - For a change to the Secure EL1&0 translation regime, the change is accompanied by a change to the **ASID**.
 - For a change to the stage 1 translations of the Non-secure EL1&0 translation regime, the change is accompanied by a change to the **ASID** or **VMID**.
 - For a change to the stage 2 translations of the Non-secure EL1&0 translation regime, the change is accompanied by a change to the **VMID**.

———— Note ————

For **ASID** and **VMID** tagged VIVT instruction caches only, for a given translation regime and a given **ASID** and **VMID**, as appropriate, invalidation is not required if a change to the translations is such that the instructions associated with the non-faulting translations of a **VA** remain unchanged through the change to the translations, even if the physical locations being mapped to by the changed translation have been written as part of changing the translation.

Examples of situations where this might occur include:

- Copy-on-Write.
- Demand Paging of memory locations to/from disk.

This does not apply for VIPT or PIPT instruction caches, because those caches hold copies of **PAs**, and therefore must be invalidated when the contents are written to, to avoid the use of stale entries.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the **VA** supplied with the operation. The effect of the invalidation might not be visible to any other aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a **PA** from an **ASID** and **VMID** tagged VIVT instruction cache is to invalidate the entire instruction cache.

The IVIPT Extension

An implementation in which the instruction cache exhibits the behaviors described in *PIPT instruction caches on page D4-1830*, or those described in *VIPT instruction caches on page D4-1830*, is said to implement the *IVIPT Extension* to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a **PA** that holds an instruction.

D4.9.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in [General TLB maintenance requirements on page D4-1815](#). If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through
- Write-Back to Non-cacheable
- Write-Through to Non-cacheable
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the shareability attributes to the required new values.

Chapter D5

The Performance Monitors Extension

This chapter describes the ARMv8 implementation of the ARM Performance Monitors, that are an optional non-invasive debug component. It describes version 3 of the *Performance Monitor Unit* (PMU) architecture, PMUv3. It contains the following sections:

- [About the Performance Monitors on page D5-1834.](#)
- [Accuracy of the Performance Monitors on page D5-1836.](#)
- [Behavior on overflow on page D5-1838.](#)
- [Attributability on page D5-1840.](#)
- [Effect of EL3 and EL2 on page D5-1841.](#)
- [Event filtering on page D5-1843.](#)
- [Performance Monitors and Debug state on page D5-1845.](#)
- [Counter enables on page D5-1846.](#)
- [Counter access on page D5-1847.](#)
- [Events, event numbers, and mnemonics on page D5-1848.](#)
- [Performance Monitors Extension registers on page D5-1871.](#)

Note

[Table K12-1 on page K12-5660](#) disambiguates the general register references used in this chapter.

D5.1 About the Performance Monitors

In ARMv8-A, the Performance Monitors Extension is an OPTIONAL feature of an implementation, but ARM strongly recommends that ARMv8-A implementations include version 3 of the Performance Monitors Extension, PMUv3.

———— **Note** —————

No previous versions of the Performance Monitors Extension can be implemented in ARMv8.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter, see [Time as measured by the Performance Monitors cycle counter on page D5-1835](#).
- A number of 32-bit event counters. The event counted by each counter is programmable. ARMv8 provides space for up to 31 counters. The actual number of counters is IMPLEMENTATION DEFINED, and the specification includes an identification mechanism.

———— **Note** —————

ARM recommends that at least two counters are implemented, and that hypervisors provide at least this many counters to guest operating systems.

- When EL2 is implemented, the required controls to partition the implemented counters into the following sets:
 - A set which is available for use by the guest operating system.
 - A set which is available for use by the hypervisor.
- Controls for:
 - Enabling and resetting counters.
 - Flagging overflows.
 - Enabling interrupts on overflow.

Monitoring software can enable the cycle counter independently of the event counters.

The PMU architecture uses event numbers to identify an event. It:

- Defines event numbers for common events, for use across many architectures and microarchitectures.

———— **Note** —————

Implementations that include PMUv3 must, as a minimum requirement, implement a subset of the common events. See [Common event numbers on page D5-1852](#).

- Reserves a large event number space for IMPLEMENTATION DEFINED events.

The full set of events for an implementation is IMPLEMENTATION DEFINED. ARM recommends that implementations include all of the events that are appropriate to the architecture profile and microarchitecture of the implementation.

When an implementation includes the Performance Monitors Extension, ARMv8 defines the following possible interfaces to the Performance Monitors Extension registers:

- A System register interface. This interface is mandatory.

———— **Note** —————

In AArch32 state, the interface is in the (coproc==0b1111) encoding space.

- An external debug interface which optionally supports memory-mapped accesses. Implementation of this interface is OPTIONAL. See [Chapter 12 Recommended External Interface to the Performance Monitors](#).

An operating system can use the System registers to access the counters.

Also, if required, the operating system can enable application software to access the counters. This enables an application to monitor its own performance with fine-grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

To enable interaction with external monitoring, an implementation might consider additional enhancements, such as providing:

- A set of events, from which a selection can be exported onto a bus for use as external events.
- The ability to count external events. This enhancement requires the implementation to include a set of external event input signals.

The Performance Monitors Extension is common to AArch64 operation and AArch32 operation. This means the ARMv8 architecture defines both AArch64 and AArch32 System registers to access the Performance Monitors. For example, the Performance Monitors Cycle Count Register is accessible as:

- When executing in AArch64 state, [PMCCNTR_EL0](#), see [PMCCNTR_EL0, Performance Monitors Cycle Count Register on page D7-2218](#).
- When executing in AArch32 state, [PMCCNTR](#), see [PMCCNTR, Performance Monitors Cycle Count Register on page G6-4762](#).

D5.1.1 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through [PMCCNTR_EL0](#) or [PMCCNTR](#), increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

———— Note —————

- This means that, in an implementation where PEs are multithreaded, the counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of [PMCCNTR_EL0](#) or [PMCCNTR](#) occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

The architecture requires that an indirect write to the [PMCCNTR_EL0](#) or [PMCCNTR](#) is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D5.1.2 Interaction with trace

It is IMPLEMENTATION DEFINED whether the implementation exports counter events to a Trace macrocell, or other external monitoring agent, to provide triggering information. The form of any exporting is also IMPLEMENTATION DEFINED. If implemented, this exporting might be enabled as part of the performance monitoring control functionality.

ARM recommends system designers include a mechanism for importing a set of external events to be counted, but such a feature is IMPLEMENTATION DEFINED. When implemented, this feature enables the Trace macrocell to pass in events to be counted.

D5.1.3 Interaction with power saving operations

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

D5.2 Accuracy of the Performance Monitors

The Performance Monitors:

- Are a non-invasive debug component. See [Non-invasive behavior](#).
- Must provide broadly accurate and statistically useful count information.

However, the Performance Monitors allow for:

- A reasonable degree of inaccuracy in the counts to keep the implementation and validation cost low. See [A reasonable degree of inaccuracy on page D5-1837](#).
- IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to put the PE in an operating state that might do one or both of the following:
 - Change the level of non-invasiveness of the Performance Monitors so that enabling an event counter can impact the performance or behavior of the PE.
 - Allow inaccurate counts. This includes, but is not limited to, cycle counts.

D5.2.1 Non-invasive behavior

The Performance Monitors are a non-invasive debug feature. A non-invasive debug feature permits the observation of data and program flow. Performance Monitors, PC Sample-based Profiling and Trace are non-invasive debug features.

Non-invasive debug components do not guarantee that they do not make any changes to the behavior or performance of the processor. Any changes that do occur must not be severe however, as this will reduce the usefulness of event counters for performance measurement and profiling. This does not include any change to program behavior that results from the same program being instrumented to use the Performance Monitors, or from some other performance monitoring process being run concurrently with the process being profiled in a multitasking operating system. As such, a reasonable variation in performance is permissible.

———— **Note** —————

Power consumption is one measure of performance. Therefore, a reasonable variation in power consumption is permissible.

ARM does not define a *reasonable variation in performance*, but recommends that such a variation is kept within 5% of normal operating performance, when averaged across a suite of code that is representative of the application workload.

———— **Note** —————

For profiles other than A-profile, there is the potential for stronger requirements. Ultimately, performance requirements are determined by end-users, and not set by the architecture.

For some common architectural events, this requirement to be non-invasive can conflict with the requirement to present an accurate value of the count under normal operating conditions. Should an implementation require more performance-invasive techniques to accurately count an event, there are the following options:

- If the event is optional, define an alternative IMPLEMENTATION DEFINED event that accurately counts the event and document the impact on performance of enabling the event.
- Provide an IMPLEMENTATION DEFINED control that disables accurate counting of the event to restore broadly accurate performance, and document the impact on performance of accurate counting.

D5.2.2 A reasonable degree of inaccuracy

The Performance Monitors provide broadly accurate and statistically useful count information. To keep the implementation and validation cost low, a reasonable degree of inaccuracy in the counts is acceptable. ARM does not define a *reasonable degree of inaccuracy* but recommends the following guidelines:

- Under normal operating conditions, the counters must present an accurate value of the count.
- In exceptional circumstances, such as a change in Security state or other boundary condition, it is acceptable for the count to be inaccurate.
- Under very unusual, non-repeating pathological cases, the counts can be inaccurate. These cases are likely to occur as a result of asynchronous exceptions, such as interrupts, where the chance of a systematic error in the count is very unlikely.

———— **Note** —————

An implementation must not introduce inaccuracies that can be triggered systematically by the execution of normal pieces of software. For example, it is not reasonable for the count of branch behavior to be inaccurate when caused by a systematic error generated by the loop structure producing a dropping in branch count.

However, dropping a single branch count as the result of a rare interaction with an interrupt is acceptable.

The permitted inaccuracy limits the possible uses of the Performance Monitors. In particular, the architecture does not define the point in a pipeline where the event counter is incremented, relative to the point where a read of the event counters is made. This means that pipelining effects can cause some imprecision.

A change of Security state can also affect the accuracy of the Performance Monitors, see [Interaction with EL3 on page D5-1841](#).

In addition to this, entry to and exit from Debug state can disturb the normal running of the PE, causing further inaccuracy in the Performance Monitors. Disabling the counters while in Debug state limits the extent of this inaccuracy. An implementation can employ methods to limit this inaccuracy, for example by promptly disabling the counters during the Debug state entry sequence.

An implementation must document any particular scenarios where significant inaccuracies are expected.

D5.3 Behavior on overflow

All events are counted in 32-bit wrapping counters, that overflow when they wrap. The cycle counter, [PMCCNTR](#), is a 64-bit wrapping counter, that is configured by [PMCR.LC](#) to either:

- Signal an overflow when bit [PMCCNTR\[63\]](#) overflows.
- Signal an overflow when bit [PMCCNTR\[31\]](#) overflows into bit [PMCCNTR\[32\]](#).

On a Performance Monitors counter overflow:

- An overflow status bit is set to 1. See [PMOVSCLR](#).
- An interrupt request is generated if the PE is configured to generate counter overflow interrupts. For more information, see [Generating overflow interrupt requests](#).
- The counter continues counting events.

D5.3.1 Generating overflow interrupt requests

Software can program the Performance Monitors so that an overflow interrupt request is generated when a counter overflows. See [PMINTENSET](#) and [PMINTENCLR](#).

———— **Note** ————

- The mechanism by which an interrupt request from the Performance Monitors generates an FIQ or IRQ exception is IMPLEMENTATION DEFINED.
- ARM recommends that the overflow interrupt requests:
 - Translate into a **PMUIRQ** signal, so that they are observable to external devices.
 - Connect to inputs on an IMPLEMENTATION DEFINED generic interrupt controller as a *Private Peripheral Interrupt* (PPI) for the originating processor. See the *ARM Generic Interrupt Controller Architecture Specification* for information about PPIs.
 - Connect to a *Cross Trigger Interface* (CTI), see [Chapter H5 The Embedded Cross-Trigger Interface](#).
- ARM strongly discourages implementations from connecting overflow interrupt requests from multiple PEs to the same *System Peripheral Interrupt* (SPI) identifier.
- From GICv3, the *ARM® Generic Interrupt Controller Architecture Specification* recommends that the *Private Peripheral Interrupt* (PPI) with ID 23 is used for overflow interrupt requests.

Counter overflow when counting one or more events generates an unsigned carry out. Software can write to the counters to control the frequency at which interrupt requests occur. For counters other than the cycle counter, the counter is always a 32-bit unsigned wrapping value. For example, software might set a counter to `0xFFFF0000`, to generate another counter overflow after 65 536 increments, and reset it to this value every time an overflow interrupt occurs.

———— **Note** ————

If an event can occur multiple times in a single clock cycle, then counter overflow can occur without the counter registering a value of zero.

The overflow interrupt request is a level-sensitive request. The PE signals a request for:

- Any given $PMNx$ counter, when the value of [PMOVSSET\[x\]](#) is 1, the value of [PMINTENSET\[x\]](#) is 1, and one of the following is true:
 - EL2 is not implemented and the value of [PMCR.E](#) is 1.
 - EL2 is implemented, x is less than the value of [HDCR.HPMN](#), and the value of [PMCR.E](#) is 1.
 - EL2 is implemented, x is greater than or equal to the value of [HDCR.HPMN](#), and the value of [HDCR.HPME](#) is 1.
- The cycle counter, when the values of [PMOVSSET\[31\]](#), [PMINTENSET\[31\]](#), and [PMCR.E](#) are all 1.

The overflow interrupt request is active in both Secure and Non-secure states. In particular, if EL3 and EL2 are both implemented, overflow events from PMN x where x is greater than or equal to the value of [HDCR.HPMN](#) can be signaled from all modes and states but only if the value of [HDCR.HPME](#) is 1.

The interrupt handler for the counter overflow request must cancel the interrupt request, by writing to [PMOVSCLR\[x\]](#) to clear the overflow bit to 0.

Pseudocode description of overflow interrupt requests

See [Chapter J1 ARMv8 Pseudocode](#) for a pseudocode description of overflow interrupt requests. The [AArch64.CheckForPMUOverflow\(\)](#) and [AArch32.CheckForPMUOverflow\(\)](#) pseudocode functions signal PMU overflow interrupt requests to an interrupt controller and PMU overflow trigger events to the cross-trigger interface.

D5.4 Attributability

An event caused by the PE counting the event is Attributable. If an agent other than the PE that is counting the events causes an event, these events are Unattributable.

An event is defined as being either Attributable or Unattributable. If the event is Attributable, it is further defined whether it is Attributable to:

- The current Security state of the PE.
- The current Exception level of the PE.
- When the PE is in Debug state, operations issued to the PE by the debugger through the external debug interface.

In a multithreaded implementation, an event might be Attributable either to the current Exception level alone, or to both the Exception level and the Security state of another PE with the same values for affinity level 1 and higher.

———— **Note** ————

An implementation is described as multithreaded when the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. In this section, when referring to a multithreaded implementation, *thread* is used to mean processing elements with different affinity level 0 values and the same values for affinity level 1 and higher.

An event can be defined as the combination of multiple subevents, which can be either Attributable or Unattributable.

All architecturally defined events are Attributable, unless otherwise stated.

Unattributable events might be counted when Attributable events are not counted. See:

- [Interaction with EL3 on page D5-1841](#).
- [Event filtering on page D5-1843](#).
- [Performance Monitors and Debug state on page D5-1845](#).

These sections are summarized by [Table D5-1](#) for events Attributable to the processor, and Unattributable events.

Table D5-1 Counting events

| Counter and PMU enabled | State | Allowed or prohibited | Filtered | Event type | | |
|-------------------------|------------|-----------------------|------------------------|-----------------------------------|------------------------|------------------------|
| | | | | If Attributable to: | Then | Else |
| Yes | Non-debug | Allowed | Not filtered | X | Count | Count |
| | | | Filtered | Current Exception level | Do not count | IMPLEMENTATION DEFINED |
| | Prohibited | X | Current Security state | Do not count | IMPLEMENTATION DEFINED | |
| | Debug | X | X | Debugger operations or raw cycles | Do not count | IMPLEMENTATION DEFINED |
| No | X | X | X | X | Do not count | Do not count |

D5.5 Effect of EL3 and EL2

This section describes the effects of implementing EL3 and EL2 on the Performance Monitors. It contains the following subsections:

- [Interaction with EL3](#).
- [Interaction with EL2 on page D5-1842](#).

D5.5.1 Interaction with EL3

While counting events is never prohibited in Non-secure state, there are some restrictions on counting events in Secure state. From reset, counting events Attributable to Secure state is prohibited in Secure state. When executing in AArch32 state, software can set [SDCR.SPME](#) to 1 to permit event counting in Secure state. In AArch64 state, software can set [MDCR_EL3.SPME](#) to 1 to permit event counting in Secure state.

———— Note ————

This enables a Secure Monitor to permit profiling within Secure state without having to configure an IMPLEMENTATION DEFINED debug authentication interface.

The system can use the external authentication interface to override SPME.

If EL3 is not implemented, the behavior is as if the value of [SDCR.SPME](#) or [MDCR_EL3.SPME](#) is 1, as appropriate.

Counting Attributable events in Secure state is prohibited unless any one of the following is true:

- EL3 is not implemented.
- EL3 is implemented, is using AArch64, and the value of [MDCR_EL3.SPME](#) is 1.
- EL3 is implemented, is using AArch32, and the value of [SDCR.SPME](#) is 1.
- EL3 is implemented, EL3 or EL1 is using AArch32, executing at EL0, and the value of [SDER32_EL3.SUNIDEN](#) is 1.
- EL3 is implemented, and counting is permitted by an IMPLEMENTATION DEFINED authentication interface, `ExternalSecureNoninvasiveDebugEnabled() == TRUE`.

———— Note ————

Software can read the Authentication Status register, [DBGAUTHSTATUS](#), to determine the state of an IMPLEMENTATION DEFINED authentication interface.

Software executing at EL3 can trap attempts by lower Exception levels to access the PMU. This means that the Secure monitor can identify any software which is using the PMU and switch contexts, if required.

The cycle counter, [PMCCNTR](#), counts even when event counting is prohibited, unless [PMCR.DP](#) is set to 1 or the PE is in Debug state.

The Performance Monitors registers are always accessible regardless of the values of the authentication signals and the [SDER.SUNIDEN](#) bit. Authentication controls whether the counters count events, it does not control access to the Performance Monitors registers.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when counting Attributable events is prohibited.

———— Note ————

- Additional controls in [PMCR](#), [HDCR](#), [PMCNTENSET](#), and [PMCNTENCLR](#) can also disable the event counters and the cycle counter.
- Controls in [PMEVTYPER<n>](#) and [PMCCFILTR](#) can also disable counting based on Exception level and Security state.

See [AArch64.CountEvents\(\)](#) and [AArch32.CountEvents\(\)](#) in [Chapter J1 ARMv8 Pseudocode](#) for more information. The [CountEvents\(\)](#) functions return TRUE if PMN_x counts events or the cycle counter counts cycles at the current Exception level and state. However, these functions do not completely describe the behavior for Unattributable events.

In AArch32 state, the Performance Monitors registers are Common registers, see [Classification of System registers on page G4-4154](#).

The Performance Monitors are intended to be broadly accurate and statistically useful, see [Accuracy of the Performance Monitors on page D5-1836](#). Some inaccuracy is permitted at the point of changing Security state, however. To avoid the leaking of information from the Secure state, the permitted inaccuracy is that transactions that are not prohibited can be uncounted. Where possible, prohibited transactions must not be counted, but if they are counted, then that counting must not degrade security.

Multithreaded implementations

If an implementation is multithreaded and the value of [PMEVTYPER<n>.MT == 1](#), then the PE does not count an event that is Attributable to Secure state on another thread if counting events Attributable to Secure state is prohibited in Secure state on the PE that is counting the events.

Example D5-1 The effect of having [PMEVTYPER<n>.MT == 1](#)

If the value of [MDCR_EL3.SPME](#) is 0 on one thread, then it does not count events Attributable to Secure state on another thread, even if one or both of the following applies:

- This thread is in Non-secure state.
- [MDCR_EL3.SPME == 1](#) on the other thread.

Otherwise:

- When the current configuration prohibits counting of events Attributable to Secure state in Secure state, it is IMPLEMENTATION DEFINED whether:
 - Counting events Attributable to Secure state on this PE in Non-secure state is permitted.
 - Counting Unattributable events related to other secure operations in the system is permitted.
- Otherwise, counting events in Non-secure state is permitted.

D5.5.2 Interaction with EL2

In an implementation that includes EL2, Non-secure software executing at EL2 can:

- Trap any attempt by the Guest OS to access the PMU. This means the hypervisor can identify which Guest OSs are using the PMU and intelligently employ switching of the PMU state.
- Trap accesses to the [PMCR](#), so that it can fully virtualize the PMU identity registers, [PMCR.IMP](#) and [PMCR.IDCODE](#).
- Reserve the highest-numbered counters for its own use by overriding the value of [PMCR.N](#) seen by the Guest OS. The PE does not permit a Guest OS to access the reserved counters.

[HDCR](#) controls Performance Monitors virtualization.

- [Counter enables on page D5-1846](#).
- [Counter access on page D5-1847](#).

D5.6 Event filtering

The PMU can filter events by various combinations of Exception level and Security state. This gives software the flexibility to count events across multiple processes.

D5.6.1 Filtering by Exception level and PE state

In AArch64 state:

- For each event counter `PMEVTYPER<n>_EL0` specifies the Exception levels in which the counter counts events Attributable to Exception levels.
- `PMCCFILTR_EL0` specifies the Exception levels in which the cycle counter counts.

In an implementation that supports multithreading:

- When the value of `PMEVTYPER<n>_EL0.MT` is 1, if an event is Attributable to another thread, then the specified filtering applies to the current Exception level and PE state of the thread to which the event is attributable, regardless of the Exception level and state of the counting thread.
- When the value of `PMEVTYPER<n>_EL0.MT` is 0, the event only counts events that are attributable to the counting thread, and the filtering applies to the Exception level and PE state of the counting state, see [Example D5-2](#).

Example D5-2 Example of the effect of the `PMEVTYPER<n>_EL0.MT` control

If the value of `PMEVTYPER<n>_EL0.U` is 0 on the current thread, then it does not count events Attributable to EL0 on the other thread, even if this thread is not executing at EL0.

Otherwise, for each Unattributable event, it is IMPLEMENTATION DEFINED whether the filtering applies.

In AArch32 state, the filtering controls are provided by the `PMEVTYPER<n>` and `PMCCFILTR` registers.

For more information, see the individual register descriptions.

Reserved combinations of the filtering controls

The filtering controls are provided by the {P, U, NSK, NSU, NSH, M} fields of the controlling register, `PMEVTYPER<n>_EL0`, `PMCCFILTR_EL0`, `PMEVTYPER<n>`, or `PMCCFILTR`.

Some combinations of these fields select filtering options that do not represent a meaningful use case, and therefore these cases are reserved. [Table D5-2](#) shows these reserved filtering encodings.

Table D5-2 Reserved filter encodings

| P | U | NSK | NSU | NSH | M | Exception level and state the filter applies to |
|---|---|-----|-----|----------|---|---|
| 0 | 1 | 1 | 1 | x | x | Secure EL1 and Non-secure EL0 ^a |
| 1 | 0 | 0 | 0 | Not 0b00 | | EL0 and at least one of EL2 and EL3 |
| 1 | 0 | 0 | 1 | Not 0b00 | | Secure EL0 and at least one of EL2 and EL3 |
| 1 | 0 | 1 | 1 | x | x | Non-secure EL1 and Secure EL0 ^a |
| 1 | 1 | 0 | 0 | 0 | 0 | None |
| 1 | 1 | 0 | 1 | Not 0b00 | | Non-secure EL0 and at least one of EL2 and EL3 |

a. Software must not program the counter to count at EL0 in one state and at EL1 in the other state.

The reserved filtering encodings shown in [Table D5-2 on page D5-1843](#) are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. Implementations must implement the filtering controls as described in the appropriate register descriptions.

D5.6.2 Accuracy of event filtering

The PMU architecture does not require event filtering to be accurate.

For most events, it is acceptable that, during a transition between states, events generated by instructions executed in one state are counted in the other state. The following sections describe the cases where event counts must not be counted in the wrong state:

- [Exception-related events](#).
- [Software increment events](#).

Exception-related events

The PMU must filter events related to exceptions and exception handling according to the Exception level in which the event occurred. These events are:

- [EXC_TAKEN on page D5-1855](#), Exception taken.
- [EXC_RETURN on page D5-1855](#), Instruction architecturally executed, condition code check pass, exception return.
- [CID_WRITE_RETIRED on page D5-1855](#), Instruction architecturally executed, condition code check pass, write to `CONTEXTIDR`.
- [TTBR_WRITE_RETIRED on page D5-1857](#), Instruction architecturally executed, condition code check pass, write to translation table base.

The PMU must not count an exception after it has been taken because this could systematically report a result of zero exceptions at EL0. Similarly, it is not acceptable for the PMU to count exception returns or writes to `CONTEXTIDR` after the return from the exception.

Software increment events

The PMU must filter software increment events according to the Exception level in which the software increment occurred. Software increment counting must also be precise, meaning the PMU must count every architecturally executed software increment event, and must not count any speculatively executed software increment.

Software increment events must also be counted without the need for explicit synchronization. For example, two software increments executed without an intervening [Context synchronization event](#) must increment the event counter twice.

For more information, see [SW_INCR on page D5-1855](#), Instruction architecturally executed, condition code check pass, software increment.

Pseudocode description of event filtering

See `AArch64.CountEvents()` and `AArch32.CountEvents()` in [Chapter J1 ARMv8 Pseudocode](#) for a pseudocode description of event filtering. However, this function does not completely describe the behavior for Unattributable events.

D5.7 Performance Monitors and Debug state

Events that count cycles are not counted in Debug state.

Events Attributable to the operations issued by the debugger through the external debug interface are not counted in Debug state.

In an implementation that supports multithreading, when the value of `PMEVTYPER<n>_EL0.MT` is 1, if an event is Attributable to an operation issued by the debugger through the external debug interface to another thread that is in Debug state, then the event is not counted, and it is IMPLEMENTATION DEFINED whether the event is counted when the counting thread is in Debug state.

For each Unattributable event, it is IMPLEMENTATION DEFINED whether it is counted when the counting PE is in Debug state. If the event might be counted, then the rules in [Filtering by Exception level and PE state on page D5-1843](#) apply for the current Security state in Debug state.

D5.8 Counter enables

Table D5-3 shows an implementation that does not include EL2, and where the `PMCR.E` bit is a global counter enable bit, and `PMCNTENSET` provides an enable bit for each counter.

Table D5-3 Event counter enables when an implementation does not include EL2

| <code>PMCR.E</code> | <code>PMCNTENSET[x] == 0</code> | <code>PMCNTENSET[x] == 1</code> |
|---------------------|---------------------------------|---------------------------------|
| 0 | PMN _x disabled | PMN _x disabled |
| 1 | PMN _x disabled | PMN _x enabled |

If the implementation includes EL2, then in addition to the `PMCR.E` and `PMCNTENSET` enable bits:

- `HDCR.HPME` overrides the value of `PMCR.E` for counters configured for access in Hyp mode.
- `HDCR.HPMN` specifies the number of performance counters that the Guest OS can access. The minimum permitted value of `HDCR.HPMN` is 1, meaning there must be at least one counter that the Guest OS can access.

Table D5-4 shows the combined effect of all the counter enable controls.

Table D5-4 Event counter enables when an implementation includes EL2

| <code>HDCR.HPME</code> | <code>PMCR.E</code> | <code>PMCNTENSET[x] == 0</code> | <code>PMCNTENSET[x] == 1</code> | |
|------------------------|---------------------|---------------------------------|---------------------------------|----------------------------|
| | | | <code>x < HDCR.HPMN</code> | <code>x ≥ HDCR.HPMN</code> |
| 0 | 0 | PMN _x disabled | PMN _x disabled | PMN _x disabled |
| 0 | 1 | PMN _x disabled | PMN _x enabled | PMN _x disabled |
| 1 | 0 | PMN _x disabled | PMN _x disabled | PMN _x enabled |
| 1 | 1 | PMN _x disabled | PMN _x enabled | PMN _x enabled |

Note

The effect of `HDCR.{HPME, HPMN}` on the counter enables applies in both Security states. However, in Secure state the value returned for `PMCR.N` is not affected by `HDCR.HPMN`.

EL2 does not affect the enabling of `PMCCNTR`. Table D5-5 shows the `PMCCNTR` enables, for all implementations.

Table D5-5 Cycle counter enables

| <code>PMCR.E</code> | <code>PMCNTENSET[31] == 0</code> | <code>PMCNTENSET[31] == 1</code> |
|---------------------|----------------------------------|----------------------------------|
| 0 | <code>PMCCNTR</code> disabled | <code>PMCCNTR</code> disabled |
| 1 | <code>PMCCNTR</code> disabled | <code>PMCCNTR</code> enabled |

D5.9 Counter access

All implemented counters are accessible in EL3, Secure EL1 and EL2. If EL2 is implemented the hypervisor uses [HDCR.HPMN](#) to reserve an event counter, with the effect that software cannot access that counter and its associated state from Non-secure EL1 or from Non-secure EL0.

———— **Note** —————

This section describes a counter as being accessible from a particular Exception level and state. However, access to the registers is subject to the access permissions described in [Access permissions on page D5-1871](#). In particular, accesses from EL0 might be UNDEFINED and accesses might be trapped to EL1 or EL2.

D5.9.1 PMNx event counters

For an implementation that includes EL2 and EL3, [Table D5-6](#) shows how the values of the [HDCR.HPMN](#) field control the behavior of accesses to the PMNx event counter registers.

Table D5-6 Result of PMNx event counter accesses

| Condition | Secure state | | | Non-secure state | | |
|---------------------------|--------------|----------|----------|------------------|-----------|-----------|
| | EL3 | EL1 | EL0 | EL2 | EL1 | EL0 |
| $x < \text{HDCR.HPMN}$ | Succeeds | Succeeds | Succeeds | Succeeds | Succeeds | Succeeds |
| $x \geq \text{HDCR.HPMN}$ | Succeeds | Succeeds | Succeeds | Succeeds | No access | No access |

Where [Table D5-6](#) shows no access:

- If [PMSELR.SEL](#) is x then:
 - A direct read of [PMXEVTYPER](#) or [PMXEVCNTR](#) is CONSTRAINED UNPREDICTABLE.
 - A direct write to [PMXEVTYPER](#) or [PMXEVCNTR](#) is CONSTRAINED UNPREDICTABLE.
- A direct read of [PMEVTYPER<n>](#) or [PMEVCNTR<n>](#) is CONSTRAINED UNPREDICTABLE.
- A direct write of [PMEVTYPER<n>](#) or [PMEVCNTR<n>](#) is CONSTRAINED UNPREDICTABLE.
- For direct reads and direct writes, [PMOVSCLR\[x\]](#), [PMOVSSSET\[x\]](#), [PMCNTENSET\[x\]](#), [PMCNTENCLR\[x\]](#), [PMINTENSET\[x\]](#), and [PMINTENCLR\[x\]](#) are RAZ/WI.
- Direct writes to [PMSWINC\[x\]](#) are ignored.
- A direct write of 1 to [PMCR.P](#) does not reset PMNx.

For more information on the CONSTRAINED UNPREDICTABLE behavior of the Performance Monitor Extension, see:

- For AArch32, [The Performance Monitors Extension on page K1-5462](#).
- For AArch64, [The Performance Monitors Extension on page K1-5480](#).

———— **Note** —————

In Secure state, and in the Non-secure EL2 mode, the value of [HDCR.HPMN](#) does not affect the value returned for [PMCR.N](#).

D5.9.2 Cycle counter

The PMU does not provide any control that a hypervisor can use to reserve the cycle counter for its own use. The only control over the cycle counter is an access permission control for EL0. See [Access permissions on page D5-1871](#).

D5.10 Events, event numbers, and mnemonics

The following sections describe the events that can be counted and their associated event numbers, and the mnemonics for the events:

- [Definitions](#).
- [The event number space on page D5-1852](#).
- [Common event numbers on page D5-1852](#).
- [Common architectural event numbers on page D5-1854](#).
- [Common microarchitectural event numbers on page D5-1859](#).
- [Meaningful ratios between common microarchitectural events on page D5-1869](#).
- [Required events on page D5-1869](#).
- [IMPLEMENTATION DEFINED event numbers on page D5-1870](#).

D5.10.1 Definitions

The following subsections give more information about terms used in the event definitions:

- [Definition of terms](#).
- [Levels of caches and TLBs on page D5-1851](#).
- [Shared caches and buses on page D5-1851](#).

Definition of terms

Speculatively executed

Many events relate to speculatively executed operations. Here, speculatively executed means the PE did some work associated with one or more instructions but the instructions were not necessarily architecturally executed.

An instruction might create one or more *microarchitectural operations* (μ -ops) at any point in the execution pipeline. For the purpose of event counting, the μ -ops are counted. The definition of a μ -op is implementation specific. An architecture instruction might create more than one μ -op for each instruction. μ -ops might also be removed or merged in the execution stream, so an architecture instruction might create no μ -ops for an instruction. Any arbitrary translation of instructions to an equivalent sequence of μ -ops is permitted.

This means there is no architecturally guaranteed relationship between a speculatively executed μ -op and an architecturally executed instruction. The results of such an operation can also be discarded, if it transpires that the operation was not required, such as a mispredicted branch. Therefore, ARMv8-A defines these events as *operation speculatively executed*, where appropriate.

———— Note —————

The definition of *speculatively executed* does not mean only those operations that are executed speculatively and later abandoned, for example due to a branch misprediction or fault. That is, speculatively executed operations must count operations on both false and correct execution paths.

The counting of operations can indicate the workload on the PE. However, there is no requirement for operations to represent similar amounts of work, and direct comparisons between different microarchitectures are not meaningful.

For example, an implementation might split an A32 or T32 LDM instruction of six registers into six μ -ops, one for each load, and a seventh address-generation operation to determine the base address or writeback address. Also, for doubleword alignment, the six load μ -ops might combine into four operations, that is, a word load, two doubleword loads, and a second word load. This single instruction can then be counted as five, or possibly six, events:

- Four (Operation speculatively executed - Load) events.
- One (Operation speculatively executed - Integer data processing) event.
- One (Operation speculatively executed - Software change of the PC) event if the PC was one of the six registers in the LDM instruction.

Different groups of events can have different IMPLEMENTATION DEFINED definitions of speculatively executed. Such groups share a common base type, which the event name denotes. Each of the events in the previous example is of the base type, operation speculatively executed.

For groups of events with a common base type, speculatively executed operations are all counted on the same basis, which normally means at the same point in the pipeline. It is possible to compare the counts and make meaningful observations about the program being profiled.

Within these groups, events are commonly defined with reference to a particular architecture instruction or group of instructions. In the case of speculatively executed operations this means operations with semantics that map to that type of instruction.

Instruction memory access

A PE acquires instructions for execution through instruction fetches. Instruction fetches might be due to:

- Fetching instructions that are architecturally executed.
- The result of the execution of an instruction preload instruction, PLI.
- Speculation that a particular instruction might be executed in the future.

The relationship between the fetch of an individual instruction and an instruction memory access is IMPLEMENTATION DEFINED. For example, an implementation might fetch many instructions including a non-integer number of instructions in a single instruction memory access.

Memory-read operations

A PE accesses memory through memory-read and memory-write operations. A memory-read operation might be due to:

- The result of an architecturally executed memory-reading instructions.
- The result of a speculatively executed memory-reading instructions.
- A translation table walk.

For levels of cache hierarchy beyond the Level 1 caches, memory-read operations also include accesses made as part of a refill of another cache closer to the PE. Such refills might be due to:

- Memory-read operations or memory-write operations that miss in the cache
- The execution of a data preload instruction.
- The execution of an instruction preload instruction on a unified cache.
- The execution of a cache maintenance instruction.

———— **Note** ————

A preload instruction or cache maintenance instruction is not, in itself, an access to that cache. However, it might generate cache refills which are then treated as memory-read operations beyond that cache.

- Speculation that a future instruction might access the memory location.

This list is not exhaustive.

The relationship between memory-read instructions and memory-read operations is IMPLEMENTATION DEFINED. For example, for some implementations an LDP instruction that reads two 64-bit registers might generate one memory-read operation if the address is quadword-aligned, but for other addresses it generates two or more memory-read operations.

Memory-write operations

Memory-write operations might be due to:

- The result of an architecturally executed memory-writing instructions.
- The result of a speculatively executed memory-writing instructions.

Note

Speculatively executed memory-writing instructions that do not become architecturally executed must not alter the architecturally defined view of memory. They can, however, generate a memory-write operation that is later undone in some implementation specific way.

For levels of cache hierarchy beyond the Level 1 caches, memory-write operations also include accesses made as part of a write-back from another cache closer to the PE. Such write-backs might be due to:

- Evicting a dirty line from the cache, to allocate a cache line for a cache refill, see memory-read operations.
- The execution of a cache maintenance instruction.

Note

A cache maintenance instruction is not in itself an access to that cache. However, it might generate write-backs which are then treated as memory-write operations beyond that cache.

- The result of a coherency request from another PE.

This list is not exhaustive.

The relationship between memory-writing instructions and memory-write operations is IMPLEMENTATION DEFINED. For example, for some implementations an STP instruction that writes two 64-bit registers might generate one memory-write operation if the address is quadword-aligned, but for other addresses it generates two or more memory-write operations. In some implementations, the result of two STR instructions that write to adjacent memory might be merged into a single memory-write operation.

Note

The data written back from a cache that is shared with other PEs might not be data that was written by the PE that performs the operation that leads to the write-back. Nevertheless, the event is counted as a write-back event for that PE.

Instruction architecturally executed

Instruction architecturally executed is a class of event that counts for each instruction of the specified type. Architecturally executed means that the program flow is such that the counted instruction would be executed in a *Simple sequential execution* of the program. Therefore an instruction that has been executed and retired is defined to be *architecturally executed*. When a PE can perform speculative execution, an instruction is not architecturally executed if the PE discards the results of the speculative execution.

If an instruction that would be executed in a *Simple sequential execution* of the program generates a synchronous exception, it is IMPLEMENTATION DEFINED whether the instruction is counted.

Each architecturally executed instruction is counted once, even if the implementation splits the instruction into multiple operations. Instructions that have no visible effect on the architectural state of the PE are architecturally executed if they form part of the architecturally executed program flow. The point where such instructions are retired is IMPLEMENTATION DEFINED.

Examples of instructions that have no visible effect are:

- A NOP.
- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.

The point at which an event causes an event counter to be updated is not defined.

Unless otherwise stated, all instructions of the specified type are counted even if they have no visible effect on the architectural state of the PE. This includes a conditional instruction that fails its condition code check.

For events that count only the execution of instructions that update context state, such as writes to the `CONTEXTIDR`, if such an instruction is executed twice without an intervening *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether the first instruction is counted.

Instruction architecturally executed, condition code check pass

Instruction architecturally executed, condition code check pass is a class of events that explicitly do not occur for:

- A conditional instruction that fails its condition code check.
- A Compare and Branch on Zero, CBZ, instruction that does not branch.
- A Compare and Branch on Nonzero, CBNZ, instruction that does not branch.
- A Test and Branch on Zero, TBZ, instruction that does not branch.
- A Test and Branch on Nonzero, TBNZ, instruction that does not branch.
- A Store-Exclusive instruction that does not write to memory.

Otherwise, the definition of architecturally executed is the same as for *Instruction architecturally executed*.

Levels of caches and TLBs

The mapping of different levels of cache or TLB to the PMU events is determined by the implementation. Although the `CLIDR_EL1`, or the AArch32 `CLIDR`, defines the implemented levels of cache, the architecture does provide any way of determining implemented levels of TLB. Also, many implementations include structures that provide some caching at a higher level than the level 1 caches or TLBs. Typically, these structures, that might be called Level 0 caches, or mini caches, or microcaches, are invisible to software. The implementation-specific nature of cache and TLB implementations mean that, in general, PMU event counts cannot be used reliably to make direct comparisons between different implementations.

Shared caches and buses

There is no architectural concept of a *shared* component. However, when a cache, a bus, or any other system component that might generate countable events is implemented, and:

- The extent of the first-order effects due to an event from that component are only applicable to a single PE, then the event is not shared.
- Otherwise, the event is shared.

Second-order effects are not considered when determining if an event is shared.

Example D5-3 First and second order effects of a cache miss in a multiple-PE implementation

In an implementation that consists of two PEs, each with its own L1 cache, a cache miss by one of the PEs is a first-order effect of an access to its cache. Any snoop that is performed on the L1 cache of the other PE in the implementation as a result of that cache miss is a second order effect.

————— Note —————

Shared events are inherently linked to microarchitectures and so the implementer must make an informed decision about how such events are implemented.

D5.10.2 The event number space

The event number space is 12 bits, and is allocated as follows:

- 0x000-0x03F Common architectural and microarchitectural event numbers.
ARM defines these event numbers. Supported events in this range can be discovered using:
- The [PMCEID0_EL0](#) and [PMCEID1_EL0](#) registers in AArch64 state.
 - The [PMCEID0](#) and [PMCEID1](#) registers in AArch32 state.
- For more information see:
- [Common event numbers](#).
 - [Common architectural event numbers on page D5-1854](#).
 - [Common microarchitectural event numbers on page D5-1859](#).
- 0x040-0x0BF ARM-recommended common architectural and microarchitectural events.
These events are IMPLEMENTATION DEFINED. For more information see:
- [IMPLEMENTATION DEFINED event numbers on page D5-1870](#).
 - [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#).
- 0x0C0-0x3FF IMPLEMENTATION DEFINED events.
For more information see [IMPLEMENTATION DEFINED event numbers on page D5-1870](#).

D5.10.3 Common event numbers

The event numbers of the common events are reserved for the specified events. Each of these event numbers must either:

- Be used for its assigned event.
- Not be used.

When an implementation supports monitoring of an event that is assigned a common event number, ARM strongly recommends that it uses that number for the event. However, software might encounter implementations where an event assigned a number in this range is monitored using an event number from the IMPLEMENTATION DEFINED range.

———— **Note** —————

ARM might define other common event numbers. This is one reason why software must not assume that an event with an assigned common event number is never monitored using an event number from the IMPLEMENTATION DEFINED range.

[Table D5-7](#) lists the PMU architectural and microarchitectural event numbers in event number order. The entries in the *Event mnemonic* column link to the event description in [Common architectural event numbers on page D5-1854](#) or [Common microarchitectural event numbers on page D5-1859](#).

Table D5-7 PMU event numbers

| Event number | Event type | Event mnemonic | Description |
|--------------|--------------------|---|---|
| 0x000 | Architectural | SW_INCR | Instruction architecturally executed, condition code check pass, software increment |
| 0x001 | Microarchitectural | L1I_CACHE_REFILL ^a | Attributable Level 1 instruction cache refill |
| 0x002 | Microarchitectural | L1I_TLB_REFILL ^a | Attributable Level 1 instruction TLB refill |
| 0x003 | Microarchitectural | L1D_CACHE_REFILL ^a | Attributable Level 1 data cache refill |

Table D5-7 PMU event numbers (continued)

| Event number | Event type | Event mnemonic | Description |
|--------------|--------------------|-------------------------------|--|
| 0x004 | Microarchitectural | L1D_CACHE | Attributable Level 1 data cache access |
| 0x005 | Microarchitectural | L1D_TLB_REFILL ^a | Attributable Level 1 data TLB refill |
| 0x006 | Architectural | LD_RETIRED | Instruction architecturally executed, condition code check pass, load |
| 0x007 | Architectural | ST_RETIRED | Instruction architecturally executed, condition code check pass, store |
| 0x008 | Architectural | INST_RETIRED | Instruction architecturally executed |
| 0x009 | Architectural | EXC_TAKEN | Exception taken |
| 0x00A | Architectural | EXC_RETURN | Instruction architecturally executed, condition code check pass, exception return |
| 0x00B | Architectural | CID_WRITE_RETIRED | Instruction architecturally executed, condition code check pass, write to CONTEXTIDR |
| 0x00C | Architectural | PC_WRITE_RETIRED | Instruction architecturally executed, condition code check pass, software change of the PC |
| 0x00D | Architectural | BR_IMMED_RETIRED | Instruction architecturally executed, immediate branch |
| 0x00E | Architectural | BR_RETURN_RETIRED | Instruction architecturally executed, condition code check pass, procedure return |
| 0x00F | Architectural | UNALIGNED_LDST_RETIRED | Instruction architecturally executed, condition code check pass, unaligned load or store |
| 0x010 | Microarchitectural | BR_MIS_PRED | Mispredicted or not predicted branch speculatively executed |
| 0x011 | Microarchitectural | CPU_CYCLES | Cycle |
| 0x012 | Microarchitectural | BR_PRED | Predictable branch speculatively executed |
| 0x013 | Microarchitectural | MEM_ACCESS | Data memory access |
| 0x014 | Microarchitectural | L1I_CACHE | Attributable Level 1 instruction cache access |
| 0x015 | Microarchitectural | L1D_CACHE_WB | Attributable Level 1 data cache write-back |
| 0x016 | Microarchitectural | L2D_CACHE | Attributable Level 2 data cache access |
| 0x017 | Microarchitectural | L2D_CACHE_REFILL ^a | Attributable Level 2 data cache refill |
| 0x018 | Microarchitectural | L2D_CACHE_WB | Attributable Level 2 data cache write-back |
| 0x019 | Microarchitectural | BUS_ACCESS | Bus access |
| 0x01A | Microarchitectural | MEMORY_ERROR | Local memory error |
| 0x01B | Microarchitectural | INST_SPEC | Operation speculatively executed |
| 0x01C | Architectural | TTBR_WRITE_RETIRED | Instruction architecturally executed, condition code check pass, write to TTBR |
| 0x01D | Microarchitectural | BUS_CYCLES | Bus cycle |

Table D5-7 PMU event numbers (continued)

| Event number | Event type | Event mnemonic | Description |
|--------------|--------------------|-------------------------------|---|
| 0x01E | Architectural | CHAIN | For odd-numbered counters, increments the count by one for each overflow of the preceding even-numbered counter. For even-numbered counters, there is no increment. |
| 0x01F | Microarchitectural | L1D_CACHE_ALLOCATE | Attributable Level 1 data cache allocation without refill |
| 0x020 | Microarchitectural | L2D_CACHE_ALLOCATE | Attributable Level 2 data cache allocation without refill |
| 0x021 | Architectural | BR_RETIRED | Instruction architecturally executed, branch |
| 0x022 | Microarchitectural | BR_MIS_PRED_RETIRED | Instruction architecturally executed, mispredicted branch |
| 0x023 | Microarchitectural | STALL_FRONTEND | No operation issued due to the frontend |
| 0x024 | Microarchitectural | STALL_BACKEND | No operation issued due to backend |
| 0x025 | Microarchitectural | L1D_TLB | Attributable Level 1 data or unified TLB access |
| 0x026 | Microarchitectural | L1I_TLB | Attributable Level 1 instruction TLB access |
| 0x027 | Microarchitectural | L2I_CACHE | Attributable Level 2 instruction cache access |
| 0x028 | Microarchitectural | L2I_CACHE_REFILL ^a | Attributable Level 2 instruction cache refill |
| 0x029 | Microarchitectural | L3D_CACHE_ALLOCATE | Attributable Level 3 data or unified cache allocation without refill |
| 0x02A | Microarchitectural | L3D_CACHE_REFILL ^a | Attributable Level 3 data or unified cache refill |
| 0x02B | Microarchitectural | L3D_CACHE | Attributable Level 3 data or unified cache access |
| 0x02C | Microarchitectural | L3D_CACHE_WB | Attributable Level 3 data or unified cache write-back |
| 0x02D | Microarchitectural | L2D_TLB_REFILL ^a | Attributable Level 2 data or unified TLB refill |
| 0x02E | Microarchitectural | L2I_TLB_REFILL ^a | Attributable Level 2 instruction TLB refill |
| 0x02F | Microarchitectural | L2D_TLB | Attributable Level 2 data or unified TLB access |
| 0x030 | Microarchitectural | L2I_TLB | Attributable Level 2 instruction TLB access |

a. For more information, see *Meaningful ratios between common microarchitectural events* on page D5-1869.

The `PMCEID0_EL0` and `PMCEID1_EL0` registers identify the events that an implementation supports.

Future revisions of this manual, or of the architecture, might define additional common event numbers. Events that do not require additional features in the PMU can be implemented retrospectively, meaning such events can be supported as part of a PMUv3 implementation.

———— **Note** —————

This means that an ARMv7 PMUv2 implementation can include support for any of the event numbers defined in [Table D5-7](#) on page D5-1852.

D5.10.4 Common architectural event numbers

This section describes the defined common architectural event numbers.

For the common features, normally the counters must increment only once for each event. The event descriptions include any exceptions to this rule.

In these definitions, the term *architecturally executed* means that the instruction flow is such that the counted instruction would have been executed in a *Simple sequential execution* model.

The common architectural event numbers are:

0x000, SW_INCR, Instruction architecturally executed, condition code check pass, software increment

The counter increments on writes to the **PMSWINC** register.

If the PE performs two architecturally executed writes to the **PMSWINC** register without an intervening *Context synchronization event*, then the counter is incremented twice.

If **PMEVTYPEPER<n>_EL0.evtCount** is set to 0x000, then in AArch64 state, counts MSR writes to **PMSWINC_EL0** with bit [n] set to 1.

If the value of **PMEVTYPEPER<n>_EL0.MT** is 1 then, in a multithreaded implementation, this counts writes by all PEs that have the same affinity at level 1 and above.

0x006, LD_RETIRED, Instruction architecturally executed, condition code check pass, load

The counter increments for every executed memory-reading instruction.

———— **Note** —————

Event 0x006 does not count the return status value of a Store-Exclusive instruction.

Whether the preload instructions PRFM, PLD, PLDW, PLI, count as memory-reading instructions is IMPLEMENTATION DEFINED. ARM recommends that if the instruction is not implemented as a NOP then it is counted as a memory-reading instruction.

0x007, ST_RETIRED, Instruction architecturally executed, condition code check pass, store

The counter increments for every executed memory-writing instruction.

DC ZVA is counted as a store.

The counter does not increment for a Store-Exclusive instruction that fails.

0x008, INST_RETIRED, Instruction architecturally executed

The counter increments for every architecturally executed instruction.

0x009, EXC_TAKEN, Exception taken

The counter increments for each exception taken. See *Exception-related events* on page D5-1844.

———— **Note** —————

The counter counts the PE exceptions described in:

- For exceptions taken to an Exception level using AArch64, *Exception entry* on page D1-1521.
- For exceptions taken to an Exception level using AArch32, *AArch32 state exception descriptions* on page G1-3849.

0x00A, EXC_RETURN, Instruction architecturally executed, condition code check pass, exception return

The counter increments for each executed exception return instruction. See also *Exception-related events* on page D5-1844. The following sections define the counted instructions:

- For an exception return from an Exception level using AArch64, *Exception return* on page D1-1536.
- For an exception return from an Exception level using AArch32, *Exception return instructions* on page G1-3834.

0x00B, CID_WRITE_RETIRED, Instruction architecturally executed, condition code check pass, write to CONTEXTIDR

The counter increments for every write to **CONTEXTIDR**. See *Exception-related events* on page D5-1844.

If the PE performs two architecturally-executed writes to `CONTEXTIDR` without an intervening *Context synchronization event*, it is CONSTRAINED UNPREDICTABLE whether the first write is counted.

0x00C, PC_WRITE_RETIRED, Instruction architecturally executed, condition code check pass, software change of the PC

The counter increments for every software change of the PC. This includes all:

- Branch instructions.
- Memory-reading instructions that explicitly write to the PC.
- Data-processing instructions that explicitly write to the PC.
- Exception return instructions, ERET and RET.

It is IMPLEMENTATION DEFINED whether the counter increments for any or all of:

- BRK and BKPT instructions.
- An exception generated because an instruction is UNDEFINED.
- The exception-generating instructions, SVC, HVC, and SMC.

It is IMPLEMENTATION DEFINED whether an ISB is counted as a software change of the PC.

The counter does not increment for exceptions other than those explicitly identified in these lists.

———— **Note** —————

Conditional branches are only counted if the branch is taken.

0x00D, BR_IMMED_RETIRED, Instruction architecturally executed, immediate branch

The counter counts all immediate branch instructions that are architecturally executed.

In AArch32 state, the counter increments each time the PE executes one of the following instructions:

- B{<c>} <label>.
- BL{<c>} <label>.
- BLX{<c>} <label>.
- CBZ <Rn>, <label>.
- CBNZ <label>.

In AArch64 state, the counter increments each time the PE executes an immediate branch instructions:

- B <label>.
- B.cond <label>.
- BL <label>.
- CBZ <Rn>, <label>.
- CBNZ <Rn>, <label>.
- TBZ <Rn>, <label>.
- TBNZ <Rn>, <label>.

———— **Note** —————

Conditional branches are always counted, regardless of whether the branch is taken.

If an ISB is counted as a software change of the PC instruction, then it is IMPLEMENTATION DEFINED whether an ISB is counted as an immediate branch instruction.

0x00E, BR_RETURN_RETIRED, Instruction architecturally executed, condition code check pass, procedure return

In AArch32 state, the counter counts the following procedure return instructions:

- BX R14.
- MOV PC, LR.
- POP {..., PC}.

- LDR PC, [SP], #offset.

———— **Note** ————

The counter counts only the listed instructions as procedure returns. For example, it does not count the following as procedure return instructions:

- BX R0, because Rm != R14.
- MOV PC, R0, because Rm != R14.
- LDM SP, {..., PC}, because writeback is not specified.
- LDR PC, [SP, #offset], because this specifies the wrong addressing mode.

In AArch64 state, the counter counts all architecturally executed RET instructions.

0x00F, UNALIGNED_LDST_RETIRED, Instruction architecturally executed, condition code check pass, unaligned load or store

The counter counts each memory-reading instruction or memory-writing instruction access that would generate an Alignment fault when Alignment fault checking is enabled.

This event does not count accesses that would generate an SP alignment fault exception if the applicable stack pointer alignment check is enabled, unless that access would also generate an Alignment fault Data Abort exception if Alignment fault checking is enabled.

It is IMPLEMENTATION DEFINED whether this event counts accesses that generate an exception, including accesses that do generate Alignment fault Data Abort exceptions.

See [SP alignment checking on page D1-1515](#) for more information.

See [Unaligned data access on page E2-2323](#) for more information.

0x01C, TTBR_WRITE_RETIRED, Instruction architecturally executed, condition code check pass, write to TTBR

The counter counts writes to [TTBR0_EL1](#) and [TTBR1_EL1](#) in AArch64 state and [TTBR0](#) and [TTBR1](#) in AArch32 state. When EL3 is implemented and using AArch32, this includes counting writes to both banked copies of [TTBR0](#) and [TTBR1](#). See [Exception-related events on page D5-1844](#).

If the PE executes two writes to the same [TTBR](#), without an intervening [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the first write to the [TTBR](#), is counted.

If EL3 is implemented and using AArch64, the counter does not count writes to [TTBR0_EL3](#).

If EL2 is implemented and using AArch64, the counter does not count writes to [TTBR0_EL2](#) and to [VTTBR_EL2](#).

If EL2 is implemented and using AArch32, the counter does not count writes to [HTTBR](#) and to [VTTBR](#).

0x01E, CHAIN

For an odd-numbered counter, increments when an overflow occurs on the preceding even-numbered counter on the same PE. Even-numbered counters never increment as a result of this event. This means the CHAIN event links the odd-numbered counter with the preceding even-numbered counter to provide a 64-bit counter.

———— **Note** ————

- The CHAIN event means a system can provide N 32-bit counters, $N/2$ 64-bit counters, or a mixture of 32-bit counters and 64-bit counters.
- The CHAIN event only counts overflows from the preceding even-numbered counter on the same PE. This means it is unaffected by the value of [PMEVTYPEPER<n>_ELO.MT](#).

There is no atomic access to a pair of counters, so if software reads a counter-pair that is enabled, it must use a high-low-high read sequence, or employ reasonable heuristics, to avoid tearing. Similarly, if using CHAIN events, when disabling the counters software must take care that the

result is not torn by the low counter overflowing at the same time as the counters are disabled
[Example D5-4 on page D5-1858](#) shows suitable sequences for disabling and enabling CHAIN counters.

Example D5-4 Usage examples for 64-bit counters

An example high-low-high read sequence for a 64-bit counter is:

```
MRS W2,PMVCNTR1_EL0    ;; read high counter, must be odd-numbered
retry:
  ISB                    ;; force ordering
  MRS W0,PMVCNTR0_EL0    ;; read low counter
                        ;; must return the previous counter to PMVCNTR1_EL0
  ISB                    ;; force ordering
  MRS W1,PMVCNTR1_EL0    ;; read high counter
  CMP W1,W2
  BNE retry              ;; if the high counter has changed, then retry
```

When disabling a pair of counters that are paired by a CHAIN event, software must:

1. Disable the low counter, by setting `PMCNTENCLR_EL0[n]` to 1.
Typically, software uses a read-modify-write sequence to update `PMCNTENCLR_EL0`.
2. Execute an ISB instruction, or perform another *Context synchronization event*.
3. Disable the high counter, by setting `PMCNTENCLR_EL0[n+1]` to 1, or setting `PMCR_EL0.E` to 0.

When enabling a pair of counters that are paired by a CHAIN event, software must:

1. Enable the high counter, by setting `PMCNTENCLR_EL0[n+1]` to 0 and, if necessary, setting `PMCR_EL0.E` to 1.
2. Execute an ISB instruction, or perform another *Context synchronization event*.
3. Enable the low counter by setting `PMCNTENCLR_EL0[n]` to 0.

When using 64-bit counters, the architecture does not define the latency between the first counter overflowing and the second counter incrementing the CHAIN event. There is no requirement for updates to occur synchronously, but software reading or enabling the counter pair using a *low-ISB-high* sequence, as shown in [Example D5-4](#), must not observe the low counter incrementing and overflowing for the event and the high counter not incrementing for the resulting CHAIN event. This means that the ISB executed after reading the low counter must ensure the completion of the update of the high counter by the CHAIN event.

Note

The way the CHAIN event operates means that, to filter the Exception levels and Security states in which the event is counted, software must:

- Program `PMEVTYPER<n>_EL0` to count the event in the required conditions.
- Program `PMEVTYPER<n+1>_EL0` to count the CHAIN event in all Exception levels and states.

0x021, BR_RETIRED, Instruction architecturally executed, branch.

The counter counts all branches on the architecturally executed path that would incur cost if mispredicted.

- Counts all branch instructions, memory-reading and data-processing instructions that explicitly write to the PC, at retirement.
- Counts both taken and not-taken branches.
- It is IMPLEMENTATION DEFINED whether this includes each of:
 - Unconditional direct branch instructions.
 - Exception-generating instructions.
 - Exception return instructions.
 - Context synchronization instructions.

D5.10.5 Common microarchitectural event numbers

This section describes the defined common microarchitectural event numbers.

The common microarchitectural events are features that are likely to be implemented across a wide range of implementations. Unlike the common architectural events, there can be some IMPLEMENTATION DEFINED variation between definitions on different implementations.

Unless otherwise stated, the common microarchitectural features relate only to events resulting from the operation of the PE counting the events. Events resulting from the operation of other PEs that might share a resource must not be counted. Where a resource can be subject to events that do not result from the operation of any of the PEs that share it, ARM recommends that the resource implements its own event counters. An example of a resource that might require its own event counters is a shared Level 2 cache that is subject to accesses from a system coherency port on that cache.

The event definitions relating to Level 2 caches generally assume the Level 2 cache is shared. The event definitions relating to Level 1 caches generally assume the Level 1 cache is not shared.

The common microarchitectural event numbers are:

0x001, L1I_CACHE_REFILL, Attributable Level 1 instruction cache refill

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 1 instruction or unified cache. This includes each instruction memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:

- [Attributability on page D5-1840.](#)
- [Meaningful ratios between common microarchitectural events on page D5-1869.](#)

0x002, L1I_TLB_REFILL, Attributable Level 1 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 1 instruction TLB. This includes each instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-1840.](#)
- [Meaningful ratios between common microarchitectural events on page D5-1869.](#)

0x003, L1D_CACHE_REFILL, Attributable Level 1 data cache refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a refill of at least the Level 1 data or unified cache from outside the Level 1 cache. Each access to a cache line that causes a new linefill is counted, including those from instructions that generate multiple accesses, such as load or store multiples, and PUSH and POP instructions. In particular, the counter counts accesses to the Level 1 cache that cause a refill that is satisfied by another Level 1 data or unified cache, or a Level 2 cache, or memory.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count:

- Accesses that do not cause a new Level 1 cache refill but are satisfied from refilling data of a previous miss.
- Accesses to a cache line that generate a memory access but not a new linefill, such as write-through writes that hit in the cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 cache, for example:
 - A write of a full cache line from a coalescing buffer.
 - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability](#) on page D5-1840.
- [Meaningful ratios between common microarchitectural events](#) on page D5-1869.

0x004, L1D_CACHE, Attributable Level 1 data cache access

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a cache access to at least the Level 1 data or unified cache. Each access to a cache line is counted including the multiple accesses of instructions, such as LDM or STM. Each access to other Level 1 data or unified memory structures, for example refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count cache maintenance instructions.

See also [Attributability](#) on page D5-1840.

0x005, L1D_TLB_REFILL, Attributable Level 1 data TLB refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB refill of at least the Level 1 data or unified TLB. It counts each read or write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability](#) on page D5-1840.
- [Meaningful ratios between common microarchitectural events](#) on page D5-1869.

0x010, BR_MIS_PRED, Mispredicted or not predicted branch speculatively executed

The counter counts each correction to the predicted program flow that occurs because of a misprediction from, or no prediction from, the branch prediction resources and that relates to instructions that the branch prediction resources are capable of predicting.

If no program-flow prediction resources are implemented, ARM recommends that the counter counts all branches that are not taken.

0x011, CPU_CYCLES, Cycle

The counter increments on every cycle.

All counters are subject to changes in clock frequency, including when a WFI or WFE instruction stops the clock. This means that it is CONSTRAINED UNPREDICTABLE whether or not CPU_CYCLES continues to increment when the clocks are stopped by WFI and WFE instructions.

———— **Note** ————

Unlike **PMCCNTR**, this count is not affected by **PMCR.DP**, **PMCR.D**, or **PMCR.C**:

- The counter is not incremented in prohibited regions, so is not affected by **PMCR.DP**.
- The counter increments on every cycle, regardless of the setting of **PMCR.D**.
- The counter is reset when event counters are reset by **PMCR.P**, never by **PMCR.C**.

In a multithreaded implementation, **CPU_CYCLES** counts each cycle for the processor for which this PE thread was active and could issue an instruction. For more information, see [Cycle event counting on multithreaded implementations on page D5-1868](#).

0x012, BR_PRED, Predictable branch speculatively executed

The counter counts every branch or other change in the program flow that the branch prediction resources are capable of predicting.

If all branches are subject to prediction, for example a BTB or BTAC, then all branches are predictable branches.

If branches are decoded before the predictor, so that the branch prediction logic dynamically predicts only some branches, for example conditional and indirect branches, then it is IMPLEMENTATION DEFINED whether other branches are counted as predictable branches. ARM recommends that all branches are counted.

An implementation might include other structures that predict branches, such as a loop buffer that predicts short backwards direct branches as taken. Each execution of such a branch is a predictable branch. Terminating the loop might generate a misprediction event that is counted by **BR_MIS_PRED**.

If no program-flow prediction resources are implemented, this event is optional, but ARM recommends that **BR_PRED** counts all branches.

0x013, MEM_ACCESS, Data memory access

The counter counts memory-read or memory-write operations that the PE made. The counter increments whether the access results in an access to a Level 1 data or unified cache, a Level 2 data or unified cache, or neither of these.

The counter does not increment as a result of:

- Instruction memory accesses, see [Definition of terms on page D5-1848](#).
- Translation table walks.
- Cache maintenance instructions.
- Write-back from any cache.
- Refilling of any cache.

0x014, L1I_CACHE, Attributable Level 1 instruction cache access

The counter counts Attributable instruction memory accesses that access at least the Level 1 instruction or unified cache. Each access to other Level 1 instruction memory structures, such as refill buffers, is also counted.

See also [Attributability on page D5-1840](#).

0x015, L1D_CACHE_WB, Attributable Level 1 data cache write-back

The counter counts every write-back of data from the Level 1 data or unified cache. The counter counts each write-back that causes data to be written from the Level 1 cache to outside of the Level 1 cache. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 2 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 1 cache.
- Transfer of data from the Level 1 cache to outside of this cache made as a result of a coherency request. The conditions determining which of these are counted for transfers to other Level 1 caches within the same multiprocessor cluster are IMPLEMENTATION DEFINED.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

Whether write-backs made as a result of cache maintenance instructions is IMPLEMENTATION DEFINED.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 2 cache or memory.
- Writes from the PE that write through the Level 1 cache to outside of the Level 1 cache.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted. See [Attributability on page D5-1840](#).

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D5-1840](#).

0x016, L2D_CACHE, Attributable Level 2 data cache access

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 2 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 data, instruction, or unified caches. Each access to other Level 2 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share this cache.
- Cache maintenance instructions.

See also [Attributability on page D5-1840](#).

0x017, L2D_CACHE_REFILL, Attributable Level 2 data cache refill

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 2 data or unified cache and cause a refill of a Level 1 data, instruction, or unified cache or of the Level 2 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1 and Level 2 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

For example, the counter counts:

- Accesses to the Level 2 cache that cause a refill that is satisfied by another Level 2 cache, a Level 3 cache, or memory.
- Refills of and write-backs from any Level 1 data, instruction or unified cache that cause a refill from outside the Level 1 and Level 2 caches.
- Accesses to the Level 2 cache that cause a refill of a Level 1 cache from outside of the Level 1 and Level 2 caches, even if there is no refill of the Level 2 cache.

The counter does not count, as events on this PE:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
- Accesses to the Level 2 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 2 cache.
- Accesses to the Level 2 cache that are part of a Level 1 cache refill or write-back that hit in the Level 2 cache so do not cause a refill from outside of the Level 1 and Level 2 caches.
- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1 and Level 2 caches, for example:
 - A write-back from a Level 1 cache to a Level 2 cache.

- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability](#) on page D5-1840.
- [Meaningful ratios between common microarchitectural events](#) on page D5-1869.

0x018, L2D_CACHE_WB, Attributable Level 2 data cache write-back

The counter counts every write-back of data from the Level 2 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 2 cache to outside the Level 1 and Level 2 caches. For example, the counter counts:

- A write-back that causes data to be written to a Level 3 cache or memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 2 cache.

Each write-back is counted once, even if it requires multiple accesses to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 2 cache to outside the Level 1 and Level 2 cache made as a result of a coherency request.
- Write-backs made as a result of Cache maintenance instructions.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 3 cache or memory.
- Writes from the PE or Level 1 data or unified cache that write through the Level 2 cache to outside the Level 1 and Level 2 caches.
- Transfers of data from the Level 2 cache to a Level 1 cache, to satisfy a Level 1 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then an Unattributable write-back event is not counted. If the cache is not shared, then the event is counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability](#) on page D5-1840.

0x019, BUS_ACCESS, Attributable Bus access

The counter counts memory-read or memory-write operations that access outside of the boundary of the PE and its closely-coupled caches. Where this boundary lies with respect to any implemented caches is IMPLEMENTATION DEFINED.

The definition of a bus access is IMPLEMENTATION DEFINED but physically is a single beat rather than a burst. That is, for each bus cycle for which the bus is active.

Bus accesses include refills of and write-backs from data, instruction, and unified caches. Whether bus accesses include operations that do use the bus but not explicitly transfer data is IMPLEMENTATION DEFINED.

An Unattributable bus access occurs when a requestor outside the PE makes a request that results in a bus access, for example, a coherency request. If the bus is shared, then an Unattributable bus access is not counted. If the bus is not shared, then the event is counted.

If the bus is shared, then only Attributable bus accesses are counted. If the bus is not shared, then all bus accesses are counted.

Where an implementation has multiple buses at this boundary, this event counts the sum of accesses across all buses.

If a bus supports multiple accesses per cycle, for example through multiple channels, the counter increments once for each channel that is active on a cycle, and so it might increment by more than one in any given cycle.

The maximum increment in any given cycle is IMPLEMENTATION DEFINED.

See also [Attributability](#) on page D5-1840.

0x01A, MEMORY_ERROR, Local memory error

The counter counts every occurrence of a memory error signaled by a memory closely coupled to this PE. The definition of local memories is IMPLEMENTATION DEFINED but includes caches, tightly-coupled memories, and TLB arrays.

Memory error refers to a physical error detected by the hardware, such as a parity or ECC error. It includes errors that are correctable and those that are not. It does not include errors as defined in the architecture, such as MMU faults.

0x01B, INST_SPEC, Operation speculatively executed

The counter counts instructions that are speculatively executed by the PE. This includes instructions that are subsequently not architecturally executed. As a result, this event counts a larger number of instructions than the number of instructions architecturally executed. The definition of speculatively executed is IMPLEMENTATION DEFINED.

0x01D, BUS_CYCLES, Bus cycle

The counter increments on every cycle of the external memory interface of the PE.

———— **Note** —————

If the implementation clocks the external memory interface at the same rate as the processor hardware, the counter counts every cycle.

0x01F, L1D_CACHE_ALLOCATE, Attributable Level 1 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 1 cache without fetching from outside the Level 1 cache, for example:

- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability](#) on page D5-1840.

0x020, L2D_CACHE_ALLOCATE, Attributable Level 2 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 2 cache without fetching from outside the Level 1 or Level 2 caches, for example:

- A write-back from a Level 1 to Level 2 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability](#) on page D5-1840.

0x022, BR_MIS_PRED_RETIRE, Instruction architecturally executed, mispredicted branch

The counter counts all instructions counted by BR_RETIRE that were not correctly predicted.

If no program-flow prediction resources are implemented, this event counts all retired not-taken branches.

0x023, STALL_FRONTEND, No operation issued due to the frontend

The counter counts every cycle counted by the CPU_CYCLES event on which no operation was issued because there are no operations available to issue for this PE from the frontend.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline.

———— **Note** —————

- For a simplified pipeline model of Fetch → Decode → Issue → Execute → Retire, ARM recommends that the events are counted when instructions are dispatched from Decode to Issue.

- On a given cycle, both events might be counted if the backend is unable to accept any operations and there are no operations available to issue from the frontend.

For more information, see [Cycle event counting on multithreaded implementations on page D5-1868](#).

0x024, STALL_BACKEND, No operation issued due to the backend

The counter counts every cycle counted by the [CPU_CYCLES](#) event on which no operation was issued because either:

- The backend is unable to accept any of the operations available for issue for this PE.
- The backend is unable to accept any operations.

For example, the back end might be unable to accept operations because of a resource conflict or non-availability.

The division between frontend and backend is IMPLEMENTATION DEFINED. Frontend and backend events must count at the same point in the pipeline. See [STALL_FRONTEND](#) for more information.

For more information, see [Cycle event counting on multithreaded implementations on page D5-1868](#).

0x025, L1D_TLB, Attributable Level 1 data or unified TLB access

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB access to at least the Level 1 data or unified TLB. Each access to a TLB record is counted including the multiple accesses of instructions, such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-1840](#).

0x026, L1I_TLB, Attributable Level 1 instruction TLB access

The counter counts each Attributable instruction memory access that causes a TLB access to at least the Level 1 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-1840](#).

0x027, L2I_CACHE, Attributable Level 2 instruction cache access

The counter counts Attributable instruction memory accesses that access at least the Level 2 instruction or unified cache. Each Attributable access to other Level 2 instruction memory structures, such as refill buffers, is also counted.

See also [Attributability on page D5-1840](#).

0x028, L2I_CACHE_REFILL, Attributable Level 2 instruction cache refill

The counter counts Attributable instruction memory accesses that cause a refill of at least the Level 2 instruction or unified cache. This includes each Attributable memory access that causes a refill from outside the cache. It excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

A refill includes any Attributable access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count cache maintenance instructions.

See also:

- [Attributability on page D5-1840](#).
- [Meaningful ratios between common microarchitectural events on page D5-1869](#).

0x029, L3D_CACHE_ALLOCATE, Attributable Level 3 data cache allocation without refill

The counter increments on every Attributable write that writes an entire line into the Level 3 cache without fetching from outside the Level 1, Level 2, or Level 3 cache, for example:

- A write-back from a Level 2 to Level 3 cache.
- A write from a coalescing buffer of a full cache line.
- A DC ZVA operation.

See also [Attributability on page D5-1840](#).

0x02A, L3D_CACHE_REFILL, Attributable Level 3 data cache refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that the PE makes that accesses at least the Level 3 data or unified cache and causes a refill of a Level 1 or Level 2 instruction, data, or unified cache or of the Level 3 data or unified cache. Each read from or write to the cache that causes a refill from outside the Level 1, Level 2, and Level 3 caches is counted.

A refill includes any access that causes data to be fetched from outside the cache, even if the data is ultimately not allocated into the cache. For example, data might be fetched into a buffer but then discarded, rather than being allocated into a cache. These buffers are treated as part of the cache.

The counter does not count as events on this PE:

- Accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.
- Accesses to the Level 3 cache that generate a memory access but not a new linefill, such as write-through writes that hit in the Level 3 cache.
- Accesses to the Level 3 cache that are part of a Level 1 or Level 2 cache refill or write-back that hit in the Level 3 cache so do not cause a refill from outside of the Level 1, Level 2, and Level 3 caches.
- Operations made by other PEs that share this cache.
- Cache maintenance instructions.
- A write that writes an entire line to the cache and does not fetch any data from outside the Level 1, Level 2, and Level 3 cache, for example:
 - A write-back from a Level 2 to Level 3 cache.
 - A write of a full cache line from a coalescing buffer.
 - A DC ZVA operation.
- A write that misses in the cache, and writes through the cache without allocating a line.

See also:

- [Attributability on page D5-1840](#).
- [Meaningful ratios between common microarchitectural events on page D5-1869](#).

0x02B, L3D_CACHE, Attributable Level 3 data cache access

The counter counts Attributable memory-read or Attributable memory-write operations, that the PE made, that access at least the Level 3 data or unified cache. Each access to a cache line is counted including refills of and write-backs from the Level 1 or Level 2 data, instruction, or unified caches. Each access to other Level 3 data or unified memory structures, such as refill buffers, write buffers, and write-back buffers, is also counted.

The counter does not count:

- Operations made by other PEs that share the Level 3 data or unified cache.
- Cache maintenance instructions.

See also [Attributability on page D5-1840](#).

0x02C, L3D_CACHE_WB, Attributable Level 3 data cache write-back

The counter counts every write-back of data from the Level 3 data or unified cache that occurs as a result of an operation by this PE. It counts each write-back that causes data to be written from the Level 3 cache to outside of the Level 1, Level 2, and Level 3 caches. For example, the counter counts the following cases:

- A write-back that causes data to be written to a Level 4 cache, or to memory.
- A write-back of a recently fetched cache line that has not been allocated to the Level 3 cache.

Each write-back is counted once, even if multiple accesses are required to complete the write-back.

It is IMPLEMENTATION DEFINED whether the counter counts:

- A transfer of data from the Level 3 cache to outside the Level 1, Level 2, and Level 3 caches made as a result of a coherency request.
- A write-back made as a result of a Cache maintenance instruction.

The counter does not count:

- The invalidation of a cache line without any write-back to a Level 4 cache or memory.
- Writes from the PE, Level 1, or Level 2 data or unified cache, that write through the Level 3 cache to outside of the Level 3 cache.
- Transfers of data from the Level 3 cache to a Level 1 or Level 2 cache, to satisfy a Level 1 or Level 2 cache refill.

An Unattributable write-back event occurs when a requestor outside the PE makes a coherency request that results in write-back. If the cache is shared, then Unattributable write-back events are not counted. If the cache is not shared, then Unattributable write-back events are counted.

It is IMPLEMENTATION DEFINED whether a write of a whole cache line that is not the result of the eviction of a line from the cache, is counted. For example, this applies when the PE determines streaming writes to memory and does not allocate lines to the cache, or by a DC ZVA operation.

See also [Attributability on page D5-1840](#).

0x02D, L2D_TLB_REFILL, Attributable Level 2 data TLB refill

The counter counts each Attributable memory-read operation or Attributable memory-write operation that causes a TLB refill of at least the Level 2 data or unified TLB. It counts each Attributable read or Attributable write that causes a refill, in the form of a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-1840](#).
- [Meaningful ratios between common microarchitectural events on page D5-1869](#).

0x02E, L2I_TLB_REFILL, Attributable Level 2 instruction TLB refill

The counter counts Attributable instruction memory accesses that cause a TLB refill of at least the Level 2 instruction TLB. This includes each Attributable instruction memory access that causes an access to a level of memory system due to a translation table walk or an access to another level of TLB caching. It is IMPLEMENTATION DEFINED whether the count increments when:

- A refill results in a Translation fault.
- A refill is not allocated in the TLB.

The counter does not count:

- A TLB miss that does not cause a refill but does generate a translation table walk.
- TLB maintenance instructions.

See also:

- [Attributability on page D5-1840](#).
- [Meaningful ratios between common microarchitectural events on page D5-1869](#).

0x02F, L2D_TLB, Attributable Level 2 data or unified TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 data or unified TLB. Each access to a TLB record is counted, including the multiple accesses of instructions such as LDM or STM.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-1840](#).

0x030, L2I_TLB, Attributable Level 2 instruction TLB access

The counter counts each Attributable memory read operation or Attributable memory write operation that causes a TLB access to at least the Level 2 instruction or unified TLB.

The counter does not count TLB maintenance instructions.

See also [Attributability on page D5-1840](#).

D5.10.6 Cycle event counting on multithreaded implementations

For most events, the event is only counted when it is attributable to the counting PE or thread, see [Attributability on page D5-1840](#).

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every cycle.
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each cycle, and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

When the `PMEVTPYPER<n>_EL0.MT` bit is set to 0, the `CPU_CYCLES` event only counts cycles on which the thread was active. For the example multithreaded implementations, this means that:

- For an SMT implementation, the `CPU_CYCLES` event counts every cycle.
- For a particular FGMT implementation, that alternates between two threads on each cycle, the `CPU_CYCLES` event counts every other cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the `CPU_CYCLES` event does not count cycles, as the PE thread is not active.

If the `PMEVTPYPER<n>_EL0.MT` bit is set to 1, the processor counts each cycle, and can only count a maximum of one cycle each cycle.

In addition, the `STALL_FRONTEND` and `STALL_BACKEND` events only count cycles that are counted by the `CPU_CYCLES` event, and so have the same limitation. For example, in an SMT implementation, if a PE thread cannot issue an instruction because of contention with other PE threads, these are counted as `STALL_BACKEND` cycles.

If the `PMEVTPYPER<n>_EL0.MT` bit is set to 1, the PE only counts cycles on which no operation is issued from any thread.

————— **Note** —————

The `PMCCNTR` register counts every processor cycle.

D5.10.7 Meaningful ratios between common microarchitectural events

The architecture highlights some meaningful ratios that can be derived from the common microarchitectural events. Table D5-8 lists the highlighted ratios.

Table D5-8 REFILL events and associated access events

| Numerator | Denominator | Ratio |
|--|----------------------------------|--|
| 0x001 L1I_CACHE_REFILL | 0x014 L1I_CACHE | Attributable Level 1 instruction cache refill rate |
| 0x002 L1I_TLB_REFILL | 0x026 L1I_TLB | Attributable Level 1 instruction TLB refill rate |
| 0x003 L1D_CACHE_REFILL | 0x004 L1D_CACHE | Attributable Level 1 data or unified cache refill rate |
| 0x005 L1D_TLB_REFILL | 0x025 L1D_TLB | Attributable Level 1 data or unified TLB refill rate |
| 0x017 L2D_CACHE_REFILL | 0x016 L2D_CACHE | Attributable Level 2 data or unified cache refill rate |
| 0x028 L2I_CACHE_REFILL | 0x027 L2I_CACHE | Attributable Level 2 instruction cache refill rate |
| 0x02A L3D_CACHE_REFILL | 0x02B L3D_CACHE | Attributable Level 3 data or unified cache refill rate |
| 0x02D L2D_TLB_REFILL | 0x02F L2D_TLB | Attributable Level 2 data or unified TLB refill rate |
| 0x02E L2I_TLB_REFILL | 0x030 L2I_TLB | Attributable Level 2 instruction TLB refill rate |
| 0x019 BUS_ACCESS | 0x01D BUS_CYCLES | Bus accesses per cycle |

D5.10.8 Required events

PMUv3 requires that an implementation includes the following common events:

- 0x000, [SW_INCR](#), Instruction architecturally executed, condition code check pass, software increment.
- 0x003, [L1D_CACHE_REFILL](#), Attributable Level 1 data cache refill.

———— **Note** —————

Event 0x003 is only required if the implementation includes a Level 1 data or unified cache.

- 0x004, [L1D_CACHE](#), Attributable Level 1 data cache access.

———— **Note** —————

Event 0x004 is only required if the implementation includes a Level 1 data or unified cache.

- 0x010, [BR_MIS_PRED](#), Mispredicted or not predicted branch speculatively executed.

———— **Note** —————

Event 0x010 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in [Common microarchitectural event numbers on page D5-1859](#).

- 0x011, [CPU_CYCLES](#), Cycle.
- 0x012, [BR_PRED](#), Predictable branch speculatively executed.

———— **Note** —————

Event 0x012 is only required if the implementation includes program-flow prediction. However, ARM recommends that the event is implemented as described in [Common microarchitectural event numbers on page D5-1859](#).

- At least one of:
 - 0x008, [INST_RETIRED](#), Instruction architecturally executed.
 - 0x01B, [INST_SPEC](#), Operation speculatively executed.

———— **Note** —————
ARM strongly recommends that event 0x008 is implemented.
—————

D5.10.9 IMPLEMENTATION DEFINED event numbers

For IMPLEMENTATION DEFINED event numbers, each counter is defined, independently, to either:

- Increment only once for each event.
- Count the duration for which an event occurs.

ARM recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common count numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, ARM recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

ARM strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Cumulative duration of stalls resulting from the holes in the instruction availability, separating out counts for key buffering points that might exist.
- Cumulative duration of data-dependent stalls, separating out counts for key dependency classes that might exist.
- Cumulative duration of stalls due to unavailability of execution resources, including, for example, write buffers, separating out counts for key resources that might exist.
- Missed superscalar issue opportunities, if relevant, separating out counts for key classes of issue that might exist.
- Miss rates for different levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.{A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist.
An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

The IMPLEMENTATION DEFINED event numbers are 0x040 to 0x3FF. [Appendix K3 Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events](#) lists the ARM recommended standardized numbering scheme for these events.

D5.11 Performance Monitors Extension registers

The following section describes the Performance Monitors Extension registers.

The following subsections give general information about the Performance Monitors Extension registers, that apply for both Execution states:

- [Relationship between AArch32 and AArch64 Performance Monitors registers.](#)
- [Access permissions.](#)

[Performance Monitors Extension registers, functional group on page G4-4205](#) summarizes the Performance Monitors Extension registers in AArch32 state.

[Instructions for accessing non-debug System registers on page C5-281](#) summarizes the Performance Monitors Extension registers in AArch64 state.

D5.11.1 Relationship between AArch32 and AArch64 Performance Monitors registers

[Table K12-2 on page K12-5662](#) lists the Performance Monitors register names for AArch32 and AArch64 states.

D5.11.2 Access permissions

Each Exception level is able to control Performance Monitors System register accesses at lower Exception levels. The access control flow is:

1. At EL0:
 - Writes to [PMUSERENR](#) are UNDEFINED.
 - Reads and writes of [PMINTENSET](#) and [PMINTENCLR](#) are UNDEFINED.
 - If [PMUSERENR.EN == 0](#):
 - If [PMUSERENR.SW == 0](#) then writes to [PMSWINC](#) are trapped to EL1.
 - If [PMUSERENR.CR == 0](#) then reads of [PMCCNTR](#) are trapped to EL1.
 - If [PMUSERENR.ER == 0](#) then reads of [PMEVCNTR<n>](#) and [PMXVCNTR](#), and reads and writes of [PMSELR](#), are trapped to EL1.
 - Otherwise, for all other Performance Monitors registers, other than reads of [PMUSERENR](#), reads and writes are trapped to EL1.

———— **Note** —————

If [HCR.TGE==1](#), then all exceptions that would be taken to EL1 are instead taken to EL2.

2. Otherwise, at EL1 and EL0 in Non-secure state, if EL2 is implemented:
 - If [HDCR.TPMCR == 1](#) then accesses to [PMCR](#) are trapped to EL2.
 - If [HDCR.TPM == 1](#) then accesses to all Performance Monitors registers, including [PMCR](#), are trapped to EL2.
3. Otherwise, at EL2, EL1 and EL0, if EL3 is implemented and using AArch64, and if [MDCR_EL3.TPM == 1](#) then accesses to all Performance Monitors registers are trapped to EL3.

———— **Note** —————

These traps are not possible if EL3 is using AArch32.

4. Otherwise, the access is permitted.

———— **Note** —————

These traps and enables only apply to System register accesses using System register access instructions. For accesses through the optional memory-mapped or external debug interfaces, see [Access permissions for external views of the Performance Monitors on page I2-5137](#).

For details of the headings used in Table D5-9, see *Configurable instruction enables and disables, and trap controls* on page D1-1562. In addition, the following terms are used:

Instruction This shows the access instruction, read (MRS), write (MSR), or both (-). In AArch32 state, the equivalent instructions are MRC and MCR.

Default access

If the *Default access* is - then the access is trapped from EL0 to EL1 unless the **PMUSERENR enables** are set to 1.

Resultant access permission

This indicates the resulting access permission provided the enables at EL0 are enabled and the traps to EL2 or EL3 are disabled.

Table D5-9 shows the access permissions for System register accesses to the Performance Monitors registers.

Table D5-9 Access permissions for the Performance Monitors System registers

| Register | Instruction | At EL0: | | Traps from below to: | | Resultant access permission |
|------------|-------------|----------------|-------------------|----------------------|------------------|-----------------------------|
| | | Default access | PMUSERENR enables | EL2 | EL3 ^a | |
| PMCR | - | - | EN | TPMCR or TPM | TPM | RW |
| PMCNTENSET | - | - | EN | TPM | TPM | RW |
| PMCNTENCLR | - | - | EN | TPM | TPM | RW |
| PMOVSCLR | - | - | EN | TPM | TPM | RW |
| PMSWINC | - | - | EN or SW | TPM | TPM | WO |
| PMSELR | - | - | EN or ER | TPM | TPM | RW |
| PMCEID0 | - | - | EN | TPM | TPM | RO |
| PMCEID1 | - | - | EN | TPM | TPM | RO |
| PMCCNTR | Read | - | EN or CR | TPM | TPM | RW |

Chapter D6

The Generic Timer in AArch64 state

This chapter describes the implementation of the ARM Generic Timer. It includes an overview of the AArch64 System register interface to an ARM Generic Timer.

It contains the following sections:

- [About the Generic Timer on page D6-1876.](#)
- [The AArch64 view of the Generic Timer on page D6-1880.](#)

[Chapter G5 The Generic Timer in AArch32 state](#) describes the AArch32 view of the Generic Timer, and [Chapter I1 System Level Implementation of the Generic Timer](#) describes the system level implementation of the Generic Timer.

D6.1 About the Generic Timer

Figure D6-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

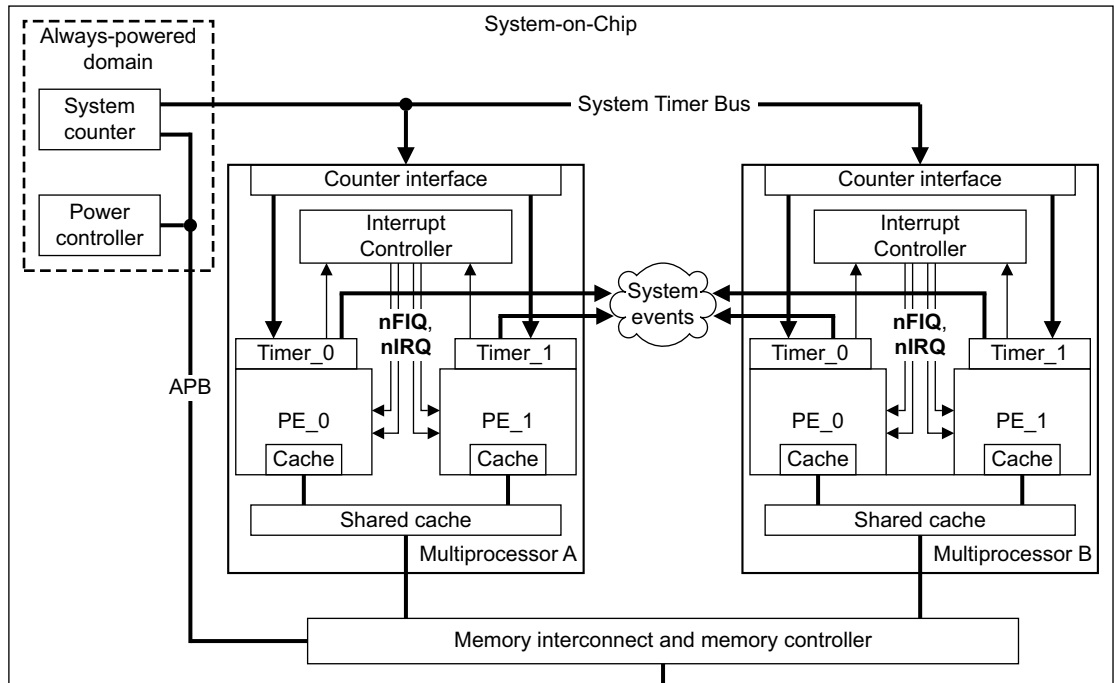

Figure D6-1 Generic Timer example

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

———— **Note** ————

The Generic Timer can also provide other components at a system level, but Figure D6-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
 - Can be used as count-up or as count-down timers.
 - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure D6-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch64 state. Chapter G5 *The Generic Timer in AArch32 state* describes access to this component from AArch32 state.

A Generic Timer implementation must also include a memory-mapped system component. This component:

- Must provide the System counter shown in Figure D6-1
- Optionally, can provide timer components for use at a system level.

Chapter II *System Level Implementation of the Generic Timer* describes this memory-mapped component.

D6.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see [The system counter on page D6-1878](#). Because this must be implemented at the system level, it is accessed through [The system level memory-mapped implementation of the Generic Timer](#). However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch64 state, the [CNTVOFF_EL2](#) register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch64 state, the timers that are accessible from AArch64 state are:
 - An EL1 physical timer.
 - An EL2 physical timer.
 - An EL3 physical timer.
 - A virtual timer.

[The AArch64 view of the Generic Timer on page D6-1880](#) describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBase N frame.
- Optionally, provides an unprivileged view of the timer in the CNTELOBase N frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

[Chapter II System Level Implementation of the Generic Timer](#) describes these components.

D6.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

| | |
|------------------|--|
| Width | At least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits. |
| Frequency | Increments at a fixed frequency, typically in the range 1-50MHz. Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving. |
| Roll-over | Roll-over time of not less than 40 years. |
| Accuracy | ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy. |
| Start-up | Starts operating from zero. |

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The `CNTFRQ_ELO` register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see [Initializing and reading the system counter frequency](#).

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

———— Note —————

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. [Gray-count scheme for timer distribution scheme on page II-5134](#) gives more information about this possibility.

Initializing and reading the system counter frequency

The `CNTFRQ_ELO` register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the `CNTFRQ_ELO` register. Only software executing at the highest implemented Exception level can write to `CNTFRQ_ELO`.

———— Note —————

The `CNTFRQ_ELO` register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the `CNTFRQ_ELO` register, to determine the current system counter frequency, in the following states:

- EL2.

- Secure and Non-secure EL1.
- When [CNTKCTL_EL1.EL0PCTEN](#) is set to 1, Secure and Non-secure EL0.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see [Chapter 11 System Level Implementation of the Generic Timer](#).

D6.2 The AArch64 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch64 state:

- [The physical counter](#).
- [The virtual counter](#) on page D6-1881.
- [Event streams](#) on page D6-1882.
- [Timers](#) on page D6-1883.

D6.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT_ELO` register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read `CNTPCT_ELO` using a 64-bit System register read.

`CNTPCT_ELO`:

- Is always accessible from EL3, Non-secure EL2 and Secure EL1 states.
- Is accessible from Non-secure EL1 only when `CNTHCTL_EL2.EL1PCTEN` is set to 1. When the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_ELO` from Non-secure EL1 is trapped to EL2.
- Is accessible from Secure EL0 state when the value of `CNTKCTL_EL1.EL0PCTEN` is 1. When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_ELO` is UNDEFINED.
- Is accessible from Non-secure EL0 when the value of `CNTHCTL_EL2.EL1PCTEN` is 1 and the value of `CNTKCTL_EL1.EL0PCTEN` is 1. Otherwise:
 - When the value of `CNTKCTL_EL1.EL0PCTEN` is 0, any attempt to access `CNTPCT_ELO` from Non-secure EL0 generates an UNDEFINED exception.
 - When the value of `CNTKCTL_EL1.EL0PCTEN` is 1 and the value of `CNTHCTL_EL2.EL1PCTEN` is 0, any attempt to access `CNTPCT_ELO` from Non-secure EL0 is trapped to EL2.

Reads of `CNTPCT_ELO` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT_ELO` must be read, an ISB is used to ensure that the read of `CNTPCT_ELO` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB                ; without this, the CNTPCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
  MRS R1, CNTPCT
```

D6.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing at Non-secure EL1 or EL0, the virtual offset value relates to the current virtual machine.

The `CNTVOFF_EL2` register contains the virtual offset. `CNTVOFF_EL2` is only accessible from EL2 and EL3.

For more information see *Status of the CNTVOFF register*.

The `CNTVCT_EL0` register holds the current virtual counter value.

Accessing the virtual counter

Software with sufficient privilege can read `CNTVCT_EL0` using a 64-bit System register read.

`CNTVCT_EL0` is always accessible from Secure EL3, from Secure EL1 when EL3 is using AArch64, and from Non-secure EL1 and EL2.

In addition, when `CNTKCTL_EL1.ELOVCTEN` is set to 1, `CNTVCT_EL0` is accessible from EL0.

When `CNTKCTL_EL1.ELOVCTEN` is set to 0, any attempt to access `CNTVCT_EL0` from EL0 is UNDEFINED.

Reads of `CNTVCT_EL0` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT_EL0` must be read, an ISB is used to ensure that the read of `CNTVCT_EL0` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB                ; without this, the CNTVCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
  MRS R1, CNTVCT
```

Status of the CNTVOFF register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the `CNTVOFF_EL2` register that defines the *virtual offset* between the physical count and the virtual count. `CNTVOFF_EL2` is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

D6.2.3 Event streams

An implementation that includes the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in [Wait for Event mechanism and Send event on page D1-1599](#).

———— **Note** —————

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The [CNTKCTL_EL1](#).{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations the [CNTHCTL_EL2](#).{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:

```
// Variables used for generation of the timer event stream.  
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;  
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
```
- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```
// TestEventCNTx()  
// =====  
  
// Template for the TestEventCNTV() and TestEventCNTP() functions  
// Describes operation when all Exception Levels are using AArch64:  
// CNTxCT_EL0 is CNTVCT_EL0 or CNTPCT_EL0 64-bit count value  
// CNTx_CTL_EL0 is CNTV_CTL_EL0 or CNTP_CTL_EL0 Control register  
// PreviousCNTxCT_EL0 is PreviousCNTVCT_EL0 or PreviousCNTPCT_EL0
```

```
TestEventCNTx()  
  if CNTx_CTL_EL0.EVNTEN == '1' then  
    n = UInt(CNTx_CTL_EL0.EVNTI);  
    SampleBit = CNTxCT_EL0<n>;  
    PreviousBit = PreviousCNTxCT_EL0<n>;  
  
    if CNTx_CTL_EL0.EVNTDIR == '0' then  
      if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();  
    else  
      if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();  
  
    PreviousCNTxCT_EL0 = CNTxCT_EL0;  
  
  return;
```

D6.2.4 Timers

In an implementation of the Generic Timer that includes EL3, if EL3 can use AArch64, the following timers are implemented:

- An EL1 physical timer, that:
 - In Secure state, can be accessed from EL1.
 - In Non-secure state, can be accessed from EL1 unless those accesses are trapped to EL2.
When this timer can be accessed from EL1, an EL1 control determines whether it can be accessed from EL0.
- A Non-secure EL2 physical timer.
- A Secure EL3 physical timer. An EL3 control determines whether this register is accessible from Secure EL1.
- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer is implemented as three registers:

- A 64-bit CompareValue register, that provides a 64-bit unsigned upcounter.
- A 32-bit TimerValue register, that provides a 32-bit signed downcounter.
- A 32-bit Control register.

Table D6-1 Timer registers summary for the Generic Timer

| Timer register | EL1 physical timer | EL2 physical timer | EL3 physical timer | Virtual timer |
|-----------------------|--------------------|--------------------|--------------------|---------------|
| CompareValue register | CNTP_CVAL_EL0 | CNTHP_CVAL_EL2 | CNTPS_CVAL_EL1 | CNTV_CVAL_EL0 |
| TimerValue register | CNTP_TVAL_EL0 | CNTHP_TVAL_EL2 | CNTPS_TVAL_EL1 | CNTV_TVAL_EL0 |
| Control register | CNTP_CTL_EL0 | CNTHP_CTL_EL2 | CNTPS_CTL_EL1 | CNTV_CTL_EL0 |

The following sections describe:

- [Accessing the timer registers](#)
- [Operation of the CompareValue views of the timers on page D6-1884](#)
- [Operation of the TimerValue views of the timers on page D6-1885.](#)

Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

EL1 physical timer Accessible from EL1, except that Non-secure software executing at EL2 controls access from Non-secure EL1.

When access from EL1 is permitted, [CNTKCTL_EL1.EL0PTEN](#) determines whether the registers are accessible from EL0. If an access is not permitted because [CNTKCTL_EL1.EL0PTEN](#) is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- The registers are accessible from EL3.
- In Non-secure state, the registers are accessible from EL2.
- [CNTHCTL_EL2.EL1PCEN](#) determines whether the Non-secure registers are accessible from Non-secure EL1. If this bit is set to 1, to enable access from Non-secure EL1, [CNTKCTL_EL1.EL0PTEN](#) determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because `CNTHCTL_EL2.ELIPCEN` is set to 0, an attempted access from a Non-secure EL1 or EL0 is trapped to EL2. However, if `CNTKCTL_EL1.EL0PTEN` is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED, and generates an exception that is taken to EL1.

EL2 physical timer Accessible from EL2 and EL3.

———— **Note** ————

In AArch32 state, the EL2 physical timer is accessible from EL3 only when the value of `SCR.NS` is 1. In AArch64 state, the EL2 physical timer is accessible from EL3 regardless of the value of `SCR_EL3.NS`.

EL3 physical timer Accessible from EL3.

`SCR_EL3.ST` determines whether the timer is also accessible from Secure EL1. The effect of the ST bit is:

- 0 The EL3 physical timer is only accessible from EL3. Attempts to access this timer from Secure EL1 generate an exception that is taken to EL3.
- 1 The EL3 physical timer is accessible from EL3 and from Secure EL1.

———— **Note** ————

The EL3 physical timer registers are always UNDEFINED in Non-secure EL1, and any attempt to access them from Non-secure EL1 generates an exception that is taken to EL1.

Virtual timer Accessible from Secure and Non-secure EL1, from EL2, and from EL3.

`CNTKCTL_EL1.EL0VTEN` determines whether the registers are accessible from EL0. If an access is not permitted because `CNTKCTL_EL1.EL0VTEN` is set to 0, an attempted access from an ELO is UNDEFINED.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, `CNTP_CTL_EL0`, `CNTHP_CTL_EL2`, `CNTPS_CTL_EL1`, or `CNTV_CTL_EL0`. For `CNTP_CTL_EL0`, the asserted interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch32 register `CNTP_CTL`.

The operation of this view of a timer is:

$$\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)$$

Where:

TimerConditionMet Is TRUE if the timer condition for this counter is met, and FALSE otherwise.

Counter The physical counter value, that can be read from the `CNTPCT_EL0` register.

———— **Note** ————

The virtual counter value, that can be read from the `CNTVCT_EL0` register, is the value:
 $(\text{Counter} - \text{Offset})$

Offset For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the `CNTVOFF_EL2` register.

CompareValue The value of the appropriate CompareValue register, `CNTP_CVAL_EL0`, `CNTHP_CVAL_EL2`, `CNTPS_CVAL_EL1`, or `CNTV_CVAL_EL0`.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

Note

This means that a timer with a CompareValue of, or close to, $0xFFFF_FFFF_FFFF_FFFF$ might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Operation of the TimerValue views of the timers

The TimerValue view of a timer operates as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, [CNTP_CTL_EL0](#), [CNTHP_CTL_EL2](#), [CNTPS_CTL_EL1](#), or [CNTV_CTL_EL0](#).

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads $\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset})) [31:0]$

Writes $\text{CompareValue} = ((\text{Counter} - \text{Offset}) [63:0] + \text{SignExtend}(\text{TimerValue})) [63:0]$

Where the arguments have the definitions used in [Operation of the CompareValue views of the timers on page D6-1884](#), and in addition:

TimerValue The value of a TimerValue register, [CNTP_TVAL_EL0](#), [CNTHP_TVAL_EL2](#), [CNTPS_TVAL_EL1](#), or [CNTV_TVAL_EL0](#).

In this view of a timer, all values are signed, in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Note

- [Operation of the CompareValue views of the timers on page D6-1884](#) gives a strict definition of `TimerConditionMet`. However, provided that the `TimerValue` is not expected to wrap as a 32-bit signed value when decremented from $0x80000000$, the `TimerValue` view can be used as giving an effect equivalent to:
 $\text{TimerConditionMet} = (\text{TimerValue} \leq 0)$
 - Programming `TimerValue` to a negative number with magnitude greater than $(\text{Counter} - \text{Offset})$ can lead to an arithmetic overflow that causes the `CompareValue` to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
-

Chapter D7

AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- *About the AArch64 System registers* on page D7-1888.
- *General system control registers* on page D7-1895.
- *Debug registers* on page D7-2147.
- *Performance Monitors registers* on page D7-2215.
- *Generic Timer registers* on page D7-2255.

D7.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- [Fixed values in the System register descriptions.](#)
- [General behavior of accesses to the AArch64 System registers.](#)
- [Principles of the ID scheme for fields in ID registers on page D7-1893.](#)

D7.1.1 Fixed values in the System register descriptions

See [Fixed values in AArch64 instruction and System register descriptions on page C2-137](#). This section defines how the glossary terms [RAZ](#), [RES0](#), [RAO](#), and [RES1](#) can be represented in the System register descriptions.

System register width

The register descriptions in this chapter describe each register as either a *32-bit register* or a *64-bit register*. For registers described as 32-bit registers, the upper bits, bits[63:32], are RES0.

D7.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- [Reset behavior of AArch64 System registers.](#)
- [Synchronization requirements for AArch64 System registers on page D7-1889.](#)

Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception Level that is using AArch64, see:

- [PE state on reset to AArch64 state on page D1-1518.](#)
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [PE state on reset to AArch64 state on page D1-1518](#) summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally unknown value.

————— Note —————

When the PE resets into an Exception Level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.

Pseudocode description of resetting System registers

The `AArch64.ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and *PE state on reset to AArch64 state* on page D1-1518.

———— **Note** —————

For debug and trace System registers this function resets registers as defined for the appropriate level of reset.

Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that any data dependencies between the instructions are respected.

———— **Note** —————

In particular, System registers that hold self-incrementing counts such as the performance counters or the Generic Timer counter or timers, can be read early. For example, where a memory access is used to communicate a read of such counters, an ISB must be inserted between the read of the memory location and the read of the Generic Timer counter, where it is necessary that the Generic Timer counter returns a count value after the memory communication.

Direct writes using the instructions in [Table C5-6 on page C5-282](#) require synchronization before software can rely on the effects of changes to the System registers to affect instructions appearing in program order after the direct write to the System register. Direct writes to these registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an ARM *Architecture Specification* or equivalent specification defines as not requiring synchronization.

Explicit synchronization occurs as a result of a *Context synchronization event*, which is one of the following events:

- Execution of an ISB instruction.
- Exception entry.
- Exception return.
- Execution of a DCPS instruction in Debug state.
- Execution of a DRPS instruction in Debug state.
- Exit from Debug state.

———— **Note** —————

The ISB and exception entry events are applicable both in Debug state and in Non-debug state.

Conceptually, explicit synchronization occurs as the first step of each of these events, so that if the event uses state that has previously been changed but was not synchronized by the time of the event, the event is guaranteed to use the state as if it had been synchronized.

———— **Note** —————

This explicit synchronization applies as the first step of the execution of the events, and does not apply to any effect of System registers that apply to the fetch and decode of the instructions that cause these events, such as breakpoints or changes to the translation table.

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- [ISR_EL1](#).
- The Generic Timer registers, that is, [CNTPCT_EL0](#) and [CNTVCT_EL0](#), and the Counter registers [CNTP_TVAL_EL0](#), [CNTV_TVAL_EL0](#), [CNTHP_TVAL_EL2](#), and [CNTPS_TVAL_EL1](#).
- [DBGCLAIMCLR_EL1](#).
- The PMU Counters, that is, [PMCCNTR_EL0](#), [PMEVCNTR<n>_EL0](#), [PMXEVCNTR_EL0](#), [PMOVSCLR_EL0](#), and [PMOVSSET_EL0](#).
- The Debug Communications Channel registers, that is, [DBGDTRRX_EL0](#), [DBGDTR_EL0](#), and [MDCCSR_EL0](#).

All other direct reads of System registers can occur in any order if synchronization has not been performed.

[Table D7-1](#) describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

Table D7-1 Synchronization requirements

| First read-write | Second read-write | Synchronization requirement |
|------------------|-------------------|---|
| Direct read | Direct read | None |
| | Direct write | None |
| | Indirect read | None |
| | Indirect write | None, see Notes on page D7-1891 |
| Direct write | Direct read | None |
| | Direct write | None |
| | Indirect read | Required |
| | Indirect write | None, see Notes on page D7-1891 |
| Indirect read | Direct read | None |
| | Direct write | None |
| | Indirect read | None |
| | Indirect write | None |
| Indirect write | Direct read | Required, see Notes on page D7-1891 |
| | Direct write | None, see Notes on page D7-1891 |
| | Indirect read | Required, see Notes on page D7-1891 |
| | Indirect write | None, see Notes on page D7-1891 |

Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in [Table D7-1 on page D7-1890](#), are defined as follows:

Direct read Where software uses a System register access instruction to read the register, see both:

- [Instructions for accessing non-debug System registers on page C5-281](#).
- [Instructions for accessing debug System registers on page C5-280](#).

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

Direct write Where software uses a System register access instruction to write to the register, see both:

- [Instructions for accessing non-debug System registers on page C5-281](#).
- [Instructions for accessing debug System registers on page C5-280](#).

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Indirect read Where an instruction uses a System register to establish operating conditions for the instruction, for example, the [TTBR](#) address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

Indirect write Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

———— **Note** —————

Since an exception is context synchronizing, registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in [Table D7-2](#), are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Table D7-2 Registers with a guarantee of observability, VMSAv8-64

| Registers | Notes |
|---|--|
| ISR_EL1 | Interrupt Status Register |
| DBGCLAIMCLR_EL1 , DBGCLAIMSET_EL1 | Debug CLAIM registers |
| CNTPCT_EL0 , CNTVCT_EL0 , CNTPTVAL_EL0 , CNTVTVAL_EL0 , CNTHTVAL_EL2 , CNTPTVAL_EL1 | Generic Timer registers |
| PMCCNTR_EL0 , PMEVCNTR<n>_EL0 , PMXEVCNTR_EL0 , PMOVSCLR_EL0 , PMOVSSET_EL0 | PMU Counters |
| DBGDTRTX_EL0 , DBGDTRRX_EL0 , DBGDTR_EL0 , and the DCC flags in MDCCSR_EL0 and EDSCR | Debug Communication Channel registers |
| EDSCR.PipeAdv | External Debug Status and Control Register PipeAdv field |

In addition to the requirements shown in [Table D7-2](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
 - [OSLAR_EL1](#). [OSLAR_EL1](#) is indirectly read to determine whether the subsequent access is permitted.
 - [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

———— **Note** —————

This requirement is stricter than the general requirement for the observability of indirect writes.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See *DCC and ITR access in Debug state* on page H4-4923.

———— **Note** —————

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.

D7.1.3 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. *ID registers to which this scheme applies* on page D7-1894 identifies the set of ID registers.

———— **Note** —————

These fields are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) { // do something that relies on the value of the feature}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0xF indicates that the feature is not implemented.
- The field value 0x0 indicates that the feature is implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {
    // Software features that depend on the presence of the hardware feature
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example D7-1](#) shows the use of such a field.

Example D7-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test `if (value >= 0x2)` can rely on features A, B, and C being present,
- Software that depends on the test `if (value >= 0x1)` can rely on feature A being present.
- If new software needs to check only that features A and B are present then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
```

```
    // Software features that depend on A and B only  
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

- The AArch64 views of the AArch32 feature ID registers given by:
 - The AArch32 Auxiliary Feature register [ID_AFR0_EL1](#).
 - The AArch32 Processor Feature registers [ID_PFR0_EL1](#) and [ID_PFR1_EL1](#).
 - The AArch32 Debug Feature register [ID_DFR0_EL1](#).
 - The AArch32 Memory Model Feature registers [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), and [ID_MMFR4_EL1](#).
 - The AArch32 Instruction Set Attribute registers [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).
 - The AArch32 Media and VFP Feature registers [MVFR0_EL1](#), [MVFR1_EL1](#), and [MVFR2_EL1](#).
- The AArch64 Auxiliary Feature registers [ID_AA64AFR0_EL1](#) and [ID_AA64AFR1_EL1](#).
- The AArch64 Processor Feature registers [ID_AA64PFR0_EL1](#) and [ID_AA64PFR1_EL1](#).
- The AArch64 Debug Feature registers [ID_AA64DFR0_EL1](#) and [ID_AA64DFR1_EL1](#).
- The AArch64 Memory Model Feature registers [ID_AA64MMFR0_EL1](#) and [ID_AA64MMFR1_EL1](#).
- The AArch64 Instruction Set Attribute registers [ID_AA64ISAR0_EL1](#) and [ID_AA64ISAR1_EL1](#).

AArch32 System registers

- The AArch32 Auxiliary Feature register [ID_AFR0](#).
- The AArch32 Processor Feature registers [ID_PFR0](#) and [ID_PFR1](#).
- The AArch32 Debug Feature register [ID_DFR0](#).
- The AArch32 Memory Model Feature registers [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), and [ID_MMFR4](#).
- The AArch32 Instruction Set Attribute registers [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), and [ID_ISAR5](#).
- The AArch32 Media and VFP Feature registers [MVFR0](#), [MVFR1](#), and [MVFR2](#).

Memory-mapped registers

- The External Debug Processor Feature register [EDPFR](#).
- The External Debug Feature register [EDDFR](#).

D7.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

D7.2.1 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TACR==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ACTLR_EL1[31:0] is architecturally mapped to AArch32 System register [ACTLR](#).

AArch64 System register ACTLR_EL1[63:32] is architecturally mapped to AArch32 System register [ACTLR2](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR_EL1 is a 64-bit register.

Field descriptions

The ACTLR_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR_EL1:

To access the ACTLR_EL1:

MRS <Xt>, ACTLR_EL1 ; Read ACTLR_EL1 into Xt
MSR ACTLR_EL1, <Xt> ; Write Xt to ACTLR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0001 | 0000 | 001 |

D7.2.2 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register ACTLR_EL2[31:0] is architecturally mapped to AArch32 System register [HACTLR](#).

AArch64 System register ACTLR_EL2[63:32] is architecturally mapped to AArch32 System register [HACTLR2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR_EL2 is a 64-bit register.

Field descriptions

The ACTLR_EL2 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR_EL2:

To access the ACTLR_EL2:

MRS <Xt>, ACTLR_EL2 ; Read ACTLR_EL2 into Xt
MSR ACTLR_EL2, <Xt> ; Write Xt to ACTLR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0000 | 001 |

D7.2.3 ACTLR_EL3, Auxiliary Control Register (EL3)

The ACTLR_EL3 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR_EL3 is a 64-bit register.

Field descriptions

The ACTLR_EL3 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR_EL3:

To access the ACTLR_EL3:

MRS <Xt>, ACTLR_EL3 ; Read ACTLR_EL3 into Xt
MSR ACTLR_EL3, <Xt> ; Write Xt to ACTLR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0000 | 001 |

D7.2.4 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register AFSR0_EL1 is architecturally mapped to AArch32 System register [ADFSR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR0_EL1 is a 32-bit register.

Field descriptions

The AFSR0_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR0_EL1:

To access the AFSR0_EL1:

MRS <Xt>, AFSR0_EL1 ; Read AFSR0_EL1 into Xt
MSR AFSR0_EL1, <Xt> ; Write Xt to AFSR0_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0101 | 0001 | 000 |

D7.2.5 AFSR0_EL2, Auxiliary Fault Status Register 0 (EL2)

The AFSR0_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register AFSR0_EL2 is architecturally mapped to AArch32 System register [HADFSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR0_EL2 is a 32-bit register.

Field descriptions

The AFSR0_EL2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR0_EL2:

To access the AFSR0_EL2:

MRS <Xt>, AFSR0_EL2 ; Read AFSR0_EL2 into Xt
MSR AFSR0_EL2, <Xt> ; Write Xt to AFSR0_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0101 | 0001 | 000 |

D7.2.6 AFSR0_EL3, Auxiliary Fault Status Register 0 (EL3)

The AFSR0_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR0_EL3 is a 32-bit register.

Field descriptions

The AFSR0_EL3 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR0_EL3:

To access the AFSR0_EL3:

MRS <Xt>, AFSR0_EL3 ; Read AFSR0_EL3 into Xt
MSR AFSR0_EL3, <Xt> ; Write Xt to AFSR0_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0101 | 0001 | 000 |

D7.2.7 AFSR1_EL1, Auxiliary Fault Status Register 1 (EL1)

The AFSR1_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register AFSR1_EL1 is architecturally mapped to AArch32 System register [AIFSR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR1_EL1 is a 32-bit register.

Field descriptions

The AFSR1_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR1_EL1:

To access the AFSR1_EL1:

MRS <Xt>, AFSR1_EL1 ; Read AFSR1_EL1 into Xt
MSR AFSR1_EL1, <Xt> ; Write Xt to AFSR1_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0101 | 0001 | 001 |

D7.2.8 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register AFSR1_EL2 is architecturally mapped to AArch32 System register [HAIFSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR1_EL2 is a 32-bit register.

Field descriptions

The AFSR1_EL2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR1_EL2:

To access the AFSR1_EL2:

MRS <Xt>, AFSR1_EL2 ; Read AFSR1_EL2 into Xt
MSR AFSR1_EL2, <Xt> ; Write Xt to AFSR1_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0101 | 0001 | 001 |

D7.2.9 AFSR1_EL3, Auxiliary Fault Status Register 1 (EL3)

The AFSR1_EL3 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AFSR1_EL3 is a 32-bit register.

Field descriptions

The AFSR1_EL3 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AFSR1_EL3:

To access the AFSR1_EL3:

MRS <Xt>, AFSR1_EL3 ; Read AFSR1_EL3 into Xt
MSR AFSR1_EL3, <Xt> ; Write Xt to AFSR1_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0101 | 0001 | 001 |

D7.2.10 AIDR_EL1, Auxiliary ID Register

The AIDR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be interpreted in conjunction with the value of [MIDR_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID1](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register AIDR_EL1 is architecturally mapped to AArch32 System register [AIDR](#).

Attributes

AIDR_EL1 is a 32-bit register.

Field descriptions

The AIDR_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AIDR_EL1:

To access the AIDR_EL1:

MRS <Xt>, AIDR_EL1 ; Read AIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 001 | 0000 | 0000 | 111 |

D7.2.11 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

AMAIR_EL1 is permitted to be cached in a TLB.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2](#).TRVM==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HCR_EL2](#).TVM==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register AMAIR_EL1[31:0] is architecturally mapped to AArch32 System register [AMAIR0](#).

AArch64 System register AMAIR_EL1[63:32] is architecturally mapped to AArch32 System register [AMAIR1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR_EL1 is a 64-bit register.

Field descriptions

The AMAIR_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR_EL1:

To access the AMAIR_EL1:

```
MRS <Xt>, AMAIR_EL1 ; Read AMAIR_EL1 into Xt
MSR AMAIR_EL1, <Xt> ; Write Xt to AMAIR_EL1
```

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1010 | 0011 | 000 |

D7.2.12 AMAIR_EL2, Auxiliary Memory Attribute Indirection Register (EL2)

The AMAIR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR_EL2](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

AMAIR_EL2 is permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register AMAIR_EL2[31:0] is architecturally mapped to AArch32 System register [HAMAIRO](#).

AArch64 System register AMAIR_EL2[63:32] is architecturally mapped to AArch32 System register [HAMAIR1](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR_EL2 is a 64-bit register.

Field descriptions

The AMAIR_EL2 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR_EL2:

To access the AMAIR_EL2:

```
MRS <Xt>, AMAIR_EL2 ; Read AMAIR_EL2 into Xt
MSR AMAIR_EL2, <Xt> ; Write Xt to AMAIR_EL2
```

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1010 | 0011 | 000 |

D7.2.13 AMAIR_EL3, Auxiliary Memory Attribute Indirection Register (EL3)

The AMAIR_EL3 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by [MAIR_EL3](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

AMAIR_EL3 is permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR_EL3 is a 64-bit register.

Field descriptions

The AMAIR_EL3 bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR_EL3:

To access the AMAIR_EL3:

MRS <Xt>, AMAIR_EL3 ; Read AMAIR_EL3 into Xt
MSR AMAIR_EL3, <Xt> ; Write Xt to AMAIR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1010 | 0011 | 000 |

D7.2.14 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

If [CSSELR_EL1](#).Level indicates a cache that is not implemented, then on a read of the CCSIDR_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR_EL1 read is treated as NOP.
- The CCSIDR_EL1 read is UNDEFINED.
- The CCSIDR_EL1 read returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2](#).TID2==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register CCSIDR_EL1 is architecturally mapped to AArch32 System register [CCSIDR](#).

The implementation includes one CCSIDR_EL1 for each cache that it can access. [CSSELR_EL1](#) selects which Cache Size ID Register is accessible.

Attributes

CCSIDR_EL1 is a 32-bit register.

Field descriptions

The CCSIDR_EL1 bit assignments are:

| | | | |
|---------|---------|---------------|----------|
| 31 | 28 27 | 13 12 | 3 2 0 |
| UNKNOWN | NumSets | Associativity | LineSize |

UNKNOWN, bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\text{Log}_2(\text{Number of bytes in cache line})$) - 4. For example:

For a line length of 16 bytes: $\text{Log}_2(16) = 4$, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: $\text{Log}_2(32) = 5$, LineSize entry = 1.

———— **Note** —————

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Accessing the CCSIDR_EL1:

To access the CCSIDR_EL1:

MRS <Xt>, CCSIDR_EL1 ; Read CCSIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 001 | 0000 | 0000 | 000 |

D7.2.15 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID2==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register CLIDR_EL1 is architecturally mapped to AArch32 System register [CLIDR](#).

Attributes

CLIDR_EL1 is a 64-bit register.

Field descriptions

The CLIDR_EL1 bit assignments are:

Bits [63:33]

Reserved, RES0.

ICB, bits [32:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

- | | |
|-----|--|
| 000 | Not disclosed by this mechanism. |
| 001 | L1 cache is the highest Inner Cacheable level. |
| 010 | L2 cache is the highest Inner Cacheable level. |
| 011 | L3 cache is the highest Inner Cacheable level. |
| 100 | L4 cache is the highest Inner Cacheable level. |
| 101 | L5 cache is the highest Inner Cacheable level. |
| 110 | L6 cache is the highest Inner Cacheable level. |

111 L7 cache is the highest Inner Cacheable level.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

- 000 No cache.
- 001 Instruction cache only.
- 010 Data cache only.
- 011 Separate instruction and data caches.
- 100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR_EL1:

To access the CLIDR_EL1:

MRS <Xt>, CLIDR_EL1 ; Read CLIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 001 | 0000 | 0000 | 001 |

D7.2.16 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HCR_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register CONTEXTIDR_EL1 is architecturally mapped to AArch32 System register [CONTEXTIDR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CONTEXTIDR_EL1 is a 32-bit register.

Field descriptions

The CONTEXTIDR_EL1 bit assignments are:

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Note

In AArch32 state, when [TTBCR.EAE](#) is set to 0, [CONTEXTIDR.ASID](#) holds the ASID.

In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either [TTBR0_EL1](#) or [TTBR1_EL1](#) holds the ASID.

Accessing the CONTEXTIDR_EL1:

To access the CONTEXTIDR_EL1:

MRS <Xt>, CONTEXTIDR_EL1 ; Read CONTEXTIDR_EL1 into Xt
MSR CONTEXTIDR_EL1, <Xt> ; Write Xt to CONTEXTIDR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1101 | 0000 | 001 |

D7.2.17 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to trace, and to Advanced SIMD and floating-point functionality.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `CPTR_EL2.TCPAC==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `CPTR_EL3.TCPAC==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register CPACR_EL1 is architecturally mapped to AArch32 System register [CPACR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CPACR_EL1 is a 32-bit register.

Field descriptions

The CPACR_EL1 bit assignments are:

Bits [31:29]

Reserved, RES0.

TTA, bit [28]

Traps EL0 and EL1 System register accesses to all implemented trace registers to EL1, from both Execution states.

- | | |
|---|---|
| 0 | EL0 and EL1 System register accesses to all implemented trace registers are not trapped to EL1. |
| 1 | EL0 and EL1 System register accesses to all implemented trace registers are trapped to EL1. |

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of `CPACR_EL1.TTA` is 1.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not implemented, this bit is RES0.

Bits [27:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps EL0 and EL1 accesses to the SIMD and floating-point registers to EL1, from both Execution states.

- | | |
|----|--|
| 00 | Causes any instructions in EL0 or EL1 that use the registers associated with floating-point and Advanced SIMD execution to be trapped. |
| 01 | Causes any instructions in EL0 that use the registers associated with floating-point and Advanced SIMD execution to be trapped, but does not cause any instruction in EL1 to be trapped. |
| 10 | Causes any instructions in EL0 or EL1 that use the registers associated with floating-point and Advanced SIMD execution to be trapped. |
| 11 | Does not cause any instruction to be trapped. |

Writes to `MVFR0`, `MVFR1` and `MVFR2` from EL1 or higher are CONstrained UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONstrained UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID do count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to `FPSID`, `MVFR0`, `MVFR1`, `MVFR2` and `FPEXC` are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of `CPACR_EL1.FPEN` is not 11.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR_EL1:

To access the CPACR_EL1:

MRS <Xt>, CPACR_EL1 ; Read CPACR_EL1 into Xt
MSR CPACR_EL1, <Xt> ; Write Xt to CPACR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0001 | 0000 | 010 |

D7.2.18 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of access to [CPACR](#), [CPACR_EL1](#), trace functionality and registers associated with Advanced SIMD and floating-point execution. Also controls EL2 access to this functionality.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [CPTR_EL3.TCPAC](#)==1, accesses to this register from EL2 are trapped to EL3.

Configurations

AArch64 System register CPTR_EL2 is architecturally mapped to AArch32 System register [HCPTR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CPTR_EL2 is a 32-bit register.

Field descriptions

The CPTR_EL2 bit assignments are:

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#) to EL2, from both Execution states.

0 This control has no effect on Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#).

1 Non-secure EL1 accesses to the [CPACR_EL1](#) or [CPACR](#) are trapped to EL2.

Note

The [CPACR_EL1](#) or [CPACR](#) is not accessible at EL0.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

Traps Non-secure System register accesses to the trace registers to EL2, from both Execution states.

- | | |
|---|---|
| 0 | Non-secure System register accesses to the trace registers are not trapped to EL2. |
| 1 | Any attempt at EL2, or Non-secure EL0 or EL1, to execute a System register access to a trace register is trapped to EL2, subject to the exception prioritization rules. |

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If System register access to the trace functionality is not supported, this bit is RES0.

Bits [19:14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps Non-secure accesses to SIMD and floating-point functionality to EL2, from both Execution states.

- | | |
|---|--|
| 0 | Does not cause any instruction to be trapped. |
| 1 | Any attempt at EL2, or Non-secure EL0 or EL1, to execute an instruction that uses the registers associated with floating-point and Advanced SIMD execution is trapped to EL2, subject to the exception prioritization rules. |

Bits [9:0]

Reserved, RES1.

Accessing the CPTR_EL2:

To access the CPTR_EL2:

MRS <Xt>, CPTR_EL2 ; Read CPTR_EL2 into Xt
MSR CPTR_EL2, <Xt> ; Write Xt to CPTR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0001 | 010 |

D7.2.19 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

Purpose

Controls trapping to EL3 of access to [CPACR_EL1](#), [CPTR_EL2](#), trace functionality and registers associated with Advanced SIMD and floating-point execution. Also controls EL3 access to trace functionality and registers associated with Advanced SIMD and floating-point execution.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CPTR_EL3 is a 32-bit register.

Field descriptions

The CPTR_EL3 bit assignments are:

TCPAC, bit [31]

Traps all of the following to EL3, from both Security states and both Execution states.

- EL2 accesses to the [CPTR_EL2](#) or [HCPTR](#).
- EL2 and EL1 accesses to the [CPACR_EL1](#) or [CPACR](#).

When CPTR_EL3.TCPAC is:

- 0 This control does not cause any accesses to [CPACR_EL1](#), [CPTR_EL2](#), [CPACR](#), or [HCPTR](#) to trap to EL3.
- 1 EL2 accesses to the [CPTR_EL2](#) or [HCPTR](#), and EL2 and EL1 accesses to the [CPACR_EL1](#) or [CPACR](#), are trapped to EL3 if they are not trapped to EL2 by the [CPTR_EL2](#).TCPAC control.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

Traps System register accesses to the trace registers, from all Exception levels, both Security states, and both Execution states, to EL3.

- 0 Does not cause any instruction to be trapped.
- 1 Any System register access to the trace registers is trapped to EL3, subject to the exception prioritization rules.

If System register access to trace functionality is not supported, this bit is RES0.

Bits [19:11]

Reserved, RES0.

TFP, bit [10]

Traps all accesses to Advanced SIMD and floating-point functionality, from all Exception levels, both Security states, and both Execution states, to EL3.

- 0 Does not cause any instruction to be trapped.
- 1 Any attempt at any Exception level to execute an instruction that uses the registers associated with Advanced SIMD and floating-point is trapped to EL3, subject to the exception prioritization rules.

Bits [9:0]

Reserved, RES0.

Accessing the CPTR_EL3:

To access the CPTR_EL3:

MRS <Xt>, CPTR_EL3 ; Read CPTR_EL3 into Xt
MSR CPTR_EL3, <Xt> ; Write Xt to CPTR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0001 | 010 |

D7.2.20 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, [CCSIDR_EL1](#), by specifying the required cache level and the cache type (either instruction or data cache).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID2](#)=1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register CSSELR_EL1 is architecturally mapped to AArch32 System register [CSSELR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CSSELR_EL1 is a 32-bit register.

Field descriptions

The CSSELR_EL1 bit assignments are:

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are:

| | |
|-----|---------------|
| 000 | Level 1 cache |
| 001 | Level 2 cache |
| 010 | Level 3 cache |
| 011 | Level 4 cache |
| 100 | Level 5 cache |

101 Level 6 cache

110 Level 7 cache

All other values are reserved.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

InD, bit [0]

Instruction not Data bit. Permitted values are:

0 Data or unified cache.

1 Instruction cache.

If CSSELR_EL1.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

Accessing the CSSELR_EL1:

To access the CSSELR_EL1:

MRS <Xt>, CSSELR_EL1 ; Read CSSELR_EL1 into Xt
MSR CSSELR_EL1, <Xt> ; Write Xt to CSSELR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 010 | 0000 | 0000 | 000 |

D7.2.21 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID2==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- If `SCTLR_EL1.UCT==0`, read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CTR_EL0 is architecturally mapped to AArch32 System register [CTR](#).

Attributes

CTR_EL0 is a 32-bit register.

Field descriptions

The CTR_EL0 bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache Writeback Granule. Log₂ of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of `0b0000` indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than `0b1001` are reserved.

ERG, bits [23:20]

Exclusives Reservation Granule. \log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of 0b0000 indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than 0b1001 are reserved.

DminLine, bits [19:16]

\log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- 01 ASID-tagged Virtual Index, Virtual Tag (AIVIVT)
- 10 Virtual Index, Physical Tag (VIPT)
- 11 Physical Index, Physical Tag (PIPT)

Other values are reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

\log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing the CTR_EL0:

To access the CTR_EL0:

MRS <Xt>, CTR_EL0 ; Read CTR_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 0000 | 0000 | 001 |

D7.2.22 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 [DACR](#) register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DACR32_EL2 is architecturally mapped to AArch32 System register [DACR](#).

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DACR32_EL2 is a 32-bit register.

Field descriptions

The DACR32_EL2 bit assignments are:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | | | | | | | | | | | | | | | | | |

D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

- 00 No access. Any access to the domain generates a Domain fault.
- 01 Client. Accesses are checked against the permission bits in the translation tables.
- 11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 10 is reserved.

Accessing the DACR32_EL2:

To access the DACR32_EL2:

MRS <Xt>, DACR32_EL2 ; Read DACR32_EL2 into Xt
MSR DACR32_EL2, <Xt> ; Write Xt to DACR32_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0011 | 0000 | 000 |

D7.2.23 DCZID_EL0, Data Cache Zero ID register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the [DC ZVA](#) (Data Cache Zero by Address) system instruction.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RO | RO | RO | RO | RO | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There are no configuration notes.

Attributes

DCZID_EL0 is a 32-bit register.

Field descriptions

The DCZID_EL0 bit assignments are:

Bits [31:5]

Reserved, RES0.

DZP, bit [4]

Data Zero prohibited. Permitted values are:

0 [DC ZVA](#) instruction is permitted.

1 [DC ZVA](#) instruction is prohibited.

The value read from this field is governed by the access state and the values of the [HCR_EL2.TDZ](#) and [SCTLR_EL1.DZE](#) bits.

BS, bits [3:0]

\log_2 of the block size in words. The maximum size supported is 2KB (value == 9).

Accessing the DCZID_EL0:

To access the DCZID_EL0:

MRS <Xt>, DCZID_EL0 ; Read DCZID_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 0000 | 0000 | 111 |

D7.2.24 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ESR_EL1 is architecturally mapped to AArch32 System register [DFSR](#). RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ESR_EL1 is a 32-bit register.

Field descriptions

See [ESR_ELx](#).

Accessing the ESR_EL1:

To access the ESR_EL1:

MRS <Xt>, ESR_EL1 ; Read ESR_EL1 into Xt
MSR ESR_EL1, <Xt> ; Write Xt to ESR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0101 | 0010 | 000 |

D7.2.25 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register ESR_EL2 is architecturally mapped to AArch32 System register [HSR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ESR_EL2 is a 32-bit register.

Field descriptions

See [ESR_ELx](#).

Accessing the ESR_EL2:

To access the ESR_EL2:

MRS <Xt>, ESR_EL2 ; Read ESR_EL2 into Xt

MSR ESR_EL2, <Xt> ; Write Xt to ESR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0101 | 0010 | 000 |

D7.2.26 ESR_EL3, Exception Syndrome Register (EL3)

The ESR_EL3 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ESR_EL3 is a 32-bit register.

Field descriptions

See [ESR_ELx](#).

Accessing the ESR_EL3:

To access the ESR_EL3:

MRS <Xt>, ESR_EL3 ; Read ESR_EL3 into Xt
MSR ESR_EL3, <Xt> ; Write Xt to ESR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0101 | 0010 | 000 |

D7.2.27 ESR_ELx, Exception Syndrome Register (ELx)

This page describes [ESR_EL1](#), [ESR_EL2](#), and [ESR_EL3](#).

The ESR_ELx characteristics are:

Purpose

Holds syndrome information for an exception taken to ELx.

Usage constraints

ESR_ELx is made UNKNOWN as a result of an exception return from ELx.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to ELx, the value of ESR_ELx is UNKNOWN. The value written to ESR_ELx must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

If EL2 is not implemented, [ESR_EL2](#) is RES0 from EL3.

Attributes

The ESR_ELx registers are 32-bit registers.

Field descriptions

The ESR_ELx bit assignments are:

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC == 000000

Unknown reason.

This value is valid for all described registers.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 000001

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

This value is valid for all described registers.

See [ISS encoding for an exception from a WFI or WFE instruction](#).

EC == 000011

Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.

This value is valid for all described registers.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000100

Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.

This value is valid for all described registers.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 000101

Trapped MCR or MRC access with (coproc==1110).

This value is valid for all described registers.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000110

Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

This value is valid for all described registers.

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 000111

Access to an Advanced SIMD or floating-point functionality trapped by [CPACR_EL1.FPEN](#), [CPTR_EL2.TFP](#), or [CPTR_EL3.TFP](#) control.

Excludes exceptions resulting from [CPACR_EL1](#) when the value of [HCR_EL2.TGE](#) is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [Reporting the EC encoding when an exception is routed to EL2](#) on page D1-1535.

This value is valid for all described registers.

See [ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP](#).

EC == 001000

Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

This value is valid for [ESR_EL2](#).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 001100

Trapped MRRC access with (coproc==1110).

This value is valid for all described registers.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 001110

Illegal Execution state.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 010001

SVC instruction execution in AArch32 state.

This is reported in [ESR_EL2](#) only when the exception is generated because the value of [HCR_EL2.TGE](#) is 1.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010010

HVC instruction execution in AArch32 state, when HVC is not disabled.

This value is valid for [ESR_EL2](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010011

SMC instruction execution in AArch32 state, when SMC is not disabled.

This is reported in ESR_EL2 only when the exception is generated because the value of [HCR_EL2.TSC](#) is 1.

This value is valid for [ESR_EL2](#) and [ESR_EL3](#).

See [ISS encoding for an exception from SMC instruction execution in AArch32 state](#).

EC == 010101

SVC instruction execution in AArch64 state.

This value is valid for all described registers.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010110

HVC instruction execution in AArch64 state, when HVC is not disabled.

This value is valid for [ESR_EL2](#) and [ESR_EL3](#).

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010111

SMC instruction execution in AArch64 state, when SMC is not disabled.

This is reported in ESR_EL2 only when the exception is generated because the value of [HCR_EL2.TSC](#) is 1.

This value is valid for [ESR_EL2](#) and [ESR_EL3](#).

See [ISS encoding for an exception from SMC instruction execution in AArch64 state](#).

EC == 011000

Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC [0b000000](#), [0b000001](#) or [0b000111](#).

This include all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-271](#), except for those exceptions reported using EC values [0b000000](#), [0b000001](#), or [0b000111](#).

This value is valid for all described registers.

See [ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state](#).

EC == 011111

IMPLEMENTATION DEFINED exception to EL3.

This value is valid for [ESR_EL3](#).

See [ISS encoding for a IMPLEMENTATION DEFINED exception to EL3](#).

EC == 100000

Instruction Abort from a lower Exception level.

Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from an Instruction Abort](#).

EC == 100001

Instruction Abort taken without a change in Exception level.

Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from an Instruction Abort](#).

EC == 100010

PC alignment fault exception.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 100100

Data Abort from a lower Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from a Data Abort](#).

EC == 100101

Data Abort taken without a change in Exception level.

Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

This value is valid for all described registers.

See [ISS encoding for an exception from a Data Abort](#).

EC == 100110

SP alignment fault exception.

This value is valid for all described registers.

See [ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault](#).

EC == 101000

Trapped floating-point exception taken from AArch32 state.

Whether this Exception class is supported is IMPLEMENTATION DEFINED.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a trapped floating-point exception](#).

EC == 101100

Trapped floating-point exception taken from AArch64 state.

Whether this Exception class is supported is IMPLEMENTATION DEFINED.

This value is valid for all described registers.

See [ISS encoding for an exception from a trapped floating-point exception](#).

EC == 101111

SError interrupt.

This value is valid for all described registers.

See [ISS encoding for an SError interrupt](#).

EC == 110000

Breakpoint exception from a lower Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 110001

Breakpoint exception taken without a change in Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 110010

Software Step exception from a lower Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Software Step exception](#).

EC == 110011

Software Step exception taken without a change in Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Software Step exception](#).

EC == 110100

Watchpoint exception from a lower Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Watchpoint exception](#).

EC == 110101

Watchpoint exception taken without a change in Exception level.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from a Watchpoint exception](#).

EC == 111000

BKPT instruction execution in AArch32 state.

This value is valid for [ESR_EL1](#) and [ESR_EL2](#).

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

EC == 111010

Vector Catch exception from AArch32 state.

The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.

This value is valid for [ESR_EL2](#).

See [ISS encoding for an exception from a Breakpoint or Vector Catch debug exception](#).

EC == 111100

BRK instruction execution in AArch64 state.

This is reported in [ESR_EL3](#) only if a BRK instruction is executed at EL3.

This value is valid for all described registers.

See [ISS encoding for an exception from execution of a Breakpoint instruction](#).

All other EC values are reserved by ARM, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-5477](#).

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

- | | |
|---|---|
| 0 | 16-bit instruction trapped. |
| 1 | 32-bit instruction trapped. This value is also used when the exception is one of the following: |
- An SError interrupt.
 - An Instruction Abort exception.
 - A PC alignment fault exception.
 - An SP alignment fault exception.
 - A Data Abort exception for which the value of the ISV bit is 0.
 - An Illegal Execution state exception.
 - Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:

| | |
|---|---|
| 0 | 16-bit T32 BKPT instruction. |
| 1 | 32-bit A32 BKPT instruction or A64 BRK instruction. |
 - An exception reported using EC value 0b000000.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number. For an exception taken from AArch32 state, [Mapping of the general-purpose registers between the Execution states on page D1-1608](#) defines this view of the specified AArch32 register. If the AArch32 register descriptor is 0b1111, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value 0b11111.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
 - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
 - The value 0b11111.

When the EC field is 0b000000, indicating an exception with an unknown reason, the ISS field is not valid, RES0.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason

This encoding is used by:

- Unknown reason.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction at the current Exception level and Security state, including:
 - A read access using a System register pattern that is not allocated for reads at the current Exception level and Security state.
 - A write access using a System register pattern that is not allocated for writes at the current Exception level and Security state.
 - Instruction encodings for instructions not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.

- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the `SCTLR_EL1`.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by `HCR_EL2.HCD` or `SCR_EL3.HCE`.
 - An SMC instruction when disabled by `SCR_EL3.SMD`.
 - An HLT instruction when disabled by `EDSCR.HDE`.
- Attempted execution of an MSR or MRS instruction to access `SP_ELO` when the value of `SPSel.SP` is 0.
- Attempted execution, in Debug state, of:
 - A DCPS1 instruction in Non-secure state from EL0 when the value of `HCR_EL2.TGE` is 1.
 - A DCPS2 instruction from EL1 or EL0 when the value of `SCR_EL3.NS` is 0, or when EL2 is not implemented.
 - A DCPS3 instruction when the value of `EDSCR.SDD` is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using `R13_mon`. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590*.
- In Debug state when the value of `EDSCR.SDD` is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (Banked register) or an MSR (Banked register) instruction to `SPSR_mon`, `SP_mon`, or `LR_mon`.
- An exception that is taken to EL2 because the value of `HCR_EL2.TGE` is 1 that, if the value of `HCR_EL2.TGE` was 0 would have been reported with an `ESR_ELx.EC` value of `0b000111`.

ISS encoding for an exception from a WFI or WFE instruction

This encoding is used by:

- Trapped WFI or WFE instruction execution.
Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

- | | |
|---|--------------|
| 0 | WFI trapped. |
| 1 | WFE trapped. |

The following sections describe configuration settings for generating this exception:

- [Traps to EL1 of EL0 execution of WFE and WFI instructions on page D1-1565.](#)
- [Traps to EL2 of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page D1-1581.](#)
- [Traps to EL3 of EL2, EL1, and EL0 execution of WFE and WFI instructions on page D1-1591.](#)

ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

- Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MCR or MRC access with (coproc==1110).
- Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states](#) on page D1-1608.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to System register space. MCR instruction.
- 1 Read from System register space. MRC or VMRS instruction.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000011:

- [Traps to EL1 of EL0 accesses to the Generic Timer registers](#) on page D1-1569.
- [Traps to EL1 of EL0 accesses to Performance Monitors registers](#) on page D1-1570.
- [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers](#) on page D1-1573.
- [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions](#) on page D1-1574.
- [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions](#) on page D1-1575.
- [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register](#) on page D1-1576.
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations](#) on page D1-1577.
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers](#) on page D1-1578.
- [Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR](#) on page D1-1582.
- [General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only](#) on page D1-1584.
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers](#) on page D1-1587.
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers](#) on page D1-1588.
- [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32](#) on page D1-1590.
- [Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR](#) on page D1-1593.
- [Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers](#) on page D1-1597.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000101:

- [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers](#) on page D1-1567.
- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers](#) on page D1-1568.
- [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers](#) on page D1-1578, for trapped accesses to the JIDR.
- [Traps to EL2 of Non-secure System register accesses to the trace registers](#) on page D1-1583.

- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1585.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1586.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1586.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)
- [Trapping System register accesses to powerdown debug registers to EL3 on page D1-1595.](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1596.](#)

[Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers on page D1-1578](#) describes configuration settings for generating exceptions that are reported using EC value 0b001000.

ISS encoding for an exception from an MCRR or MRRC access

This encoding is used by:

- Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MRRC access with (coproc==1110).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-1608.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See *Mapping of the general-purpose registers between the Execution states* on page D1-1608.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to System register space. MCRR instruction.
- 1 Read from System register space. MRRC instruction.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b000100:

- *Traps to EL1 of EL0 accesses to the Generic Timer registers* on page D1-1569.
- *Traps to EL1 of EL0 accesses to Performance Monitors registers* on page D1-1570.
- *Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers* on page D1-1573.
- *General trapping to EL2 of Non-secure EL0 and EL1 accesses to System registers, from AArch32 state only* on page D1-1584.
- *Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers* on page D1-1587.
- *Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page D1-1588.
- *Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers* on page D1-1597.

The following sections describe configuration settings for generating exceptions that are reported using EC value 0b001100:

- *Traps to EL1 of EL0 and EL1 System register accesses to the trace registers* on page D1-1567.
- *Traps to EL1 of EL0 accesses to the Debug Communications Channel (DCC) registers* on page D1-1568.
- *Traps to EL2 of Non-secure System register accesses to the trace registers* on page D1-1583.

- [Trapping System register accesses to Debug ROM registers to EL2 on page D1-1585.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)
- [Trapping System register accesses to powerdown debug registers to EL2 on page D1-1586.](#)

ISS encoding for an exception from an LDC or STC instruction

This encoding is used by:

- Trapped LDC or STC access.
The only architected uses of these instructions are:
 - An STC to write data to memory from [DBGDTRRXint](#).
 - An LDC to read data from memory to [DBGDTRTXint](#).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.

- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

imm8, bits [19:12]

The immediate value from the issued instruction.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer. The reported value gives the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-1608](#).

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

- 0 Subtract offset.
- 1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- 000 Immediate unindexed.
- 001 Immediate post-indexed.
- 010 Immediate offset.
- 011 Immediate pre-indexed.
- 100 Literal unindexed.
LDC instruction in A32 instruction set only.
For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
- 110 Literal offset.
LDC instruction only.
For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-5492](#).

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to memory. STC instruction.
- 1 Read from memory. LDC instruction.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000110:

- [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers on page D1-1568.](#)
- [Trapping general System register accesses to debug registers to EL2 on page D1-1586.](#)
- [Trapping general System register accesses to debug registers to EL3 on page D1-1596.](#)

ISS encoding for an exception from an access to an Advanced SIMD or floating-point register, resulting from CPACR_EL1.FPEN or CPTR_ELx.TFP

This encoding is used by:

- Access to an Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control.
Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000 as described in [Reporting the EC encoding when an exception is routed to EL2 on page D1-1535.](#)

The ISS encoding for these exceptions is:

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.

For an implementation that does not include floating-point or Advanced SIMD, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:0]

Reserved, RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- [Traps to EL1 of EL0 and EL1 accesses to SIMD and floating-point functionality on page D1-1568.](#)
- [General trapping to EL2 of Non-secure accesses to the SIMD and floating-point registers on page D1-1583.](#)
- [Traps to EL3 of all System register accesses to the trace registers on page D1-1594.](#)

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

This encoding is used by:

- Illegal Execution state.
- PC alignment fault exception.
- SP alignment fault exception.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. [SP alignment checking on page D1-1515](#) describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from HVC or SVC instruction execution

This encoding is used by:

- SVC instruction execution in AArch32 state.
This is reported in ESR_EL2 only when the exception is generated because the value of [HCR_EL2.TGE](#) is 1.
- HVC instruction execution in AArch32 state, when HVC is not disabled.
- SVC instruction execution in AArch64 state.

- HVC instruction execution in AArch64 state, when HVC is not disabled.

The ISS encoding for these exceptions is:

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see [SVC](#), and [HVC](#).

For A64 instructions, see [SVC](#) and [HVC](#).

ISS encoding for an exception from SMC instruction execution in AArch32 state

This encoding is used by:

- SMC instruction execution in AArch32 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of [HCR_EL2.TSC](#) is 1.

The ISS encoding for these exceptions is:

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from Non-secure EL1 because [HCR_EL2.TSC](#) is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

COND, bits [23:20]

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch64, this field is set to 0b1110.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
 - If the instruction is conditional, COND is set to the condition code field value from the instruction.
 - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
 - With COND set to 0b1110, the value for unconditional.
 - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
 - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
 - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

- 0 The instruction was unconditional, or was conditional and passed its condition code check.
- 1 The instruction was conditional, and might have failed its condition code check.

————— Note —————

In an implementation in which an SMC instruction that fails its code check is not trapped, this field can always return the value 0.

Bits [18:0]

Reserved, RES0.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578](#) describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and [System calls on page D1-1598](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from SMC instruction execution in AArch64 state

This encoding is used by:

- SMC instruction execution in AArch64 state, when SMC is not disabled.
This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.

The ISS encoding for these exceptions is:

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from Non-secure EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

[Traps to EL2 of Non-secure EL1 execution of SMC instructions on page D1-1578](#) describes the configuration settings for trapping SMC instructions from Non-secure EL1 modes, and [System calls on page D1-1598](#) describes the case where these exceptions are trapped to EL3.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

This encoding is used by:

- Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC 0b000000, 0b000001 or 0b000111.
This include all instructions that cause exceptions that are part of the encoding space defined in [System instruction class encoding overview on page C5-271](#), except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.

The ISS encoding for these exceptions is:

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

Op2, bits [19:17]

The Op2 value from the issued instruction.

Op1, bits [16:14]

The Op1 value from the issued instruction.

CRn, bits [13:10]

The CRn value from the issued instruction.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- | | |
|---|---|
| 0 | Write access, including MSR instructions. |
| 1 | Read access, including MRS instructions. |

For exceptions caused by System instructions, see [System](#) on page C4-199 for the encoding values returned by an instruction.

The following sections describe configuration settings for generating the exception that is reported using EC value 0b011000:

- In [EL1 configurable controls](#) on page D1-1563.
 - [Traps to EL1 of EL0 execution of cache maintenance instructions](#) on page D1-1564.
 - [Traps to EL1 of EL0 accesses to the CTR_EL0](#) on page D1-1565.
 - [Traps to EL1 of EL0 execution of DC ZVA instructions](#) on page D1-1566.
 - [Traps to EL1 of EL0 accesses to the PSTATE.{D, A, I, F} interrupt masks](#) on page D1-1566.
 - [Traps to EL1 of EL0 and EL1 System register accesses to the trace registers](#) on page D1-1567.
 - [Traps to EL1 of EL0 accesses to the Debug Communications Channel \(DCC\) registers](#) on page D1-1568.
 - [Traps to EL1 of EL0 accesses to the Generic Timer registers](#) on page D1-1569.
 - [Traps to EL1 of EL0 accesses to Performance Monitors registers](#) on page D1-1570.
- In [EL2 configurable controls](#) on page D1-1571.
 - [Traps to EL2 of Non-secure EL1 accesses to virtual memory control registers](#) on page D1-1573.
 - [Traps to EL2 of Non-secure EL0 and EL1 execution of DC ZVA instructions](#) on page D1-1574.
 - [Traps to EL2 of Non-secure EL1 execution of TLB maintenance instructions](#) on page D1-1574.
 - [Traps to EL2 of Non-secure EL0 and EL1 execution of cache maintenance instructions](#) on page D1-1575.
 - [Traps to EL2 of Non-secure EL1 accesses to the Auxiliary Control Register](#) on page D1-1576.
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations](#) on page D1-1577.
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the ID registers](#) on page D1-1578.
 - [Trapping to EL2 of Non-secure EL1 accesses to the CPACR_EL1 or CPACR](#) on page D1-1582.
 - [Traps to EL2 of Non-secure System register accesses to the trace registers](#) on page D1-1583.
 - [Trapping System register accesses to Debug ROM registers to EL2](#) on page D1-1585.
 - [Trapping System register accesses to powerdown debug registers to EL2](#) on page D1-1586.
 - [Traps to EL2 of Non-secure EL0 and EL1 accesses to the Generic Timer registers](#) on page D1-1587.

- *Trapping general System register accesses to debug registers to EL2 on page D1-1586.*
- *Traps to EL2 of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page D1-1588.*
- *In EL3 configurable controls on page D1-1589.*
 - *Traps to EL3 of Secure EL1 accesses to the Counter-timer Physical Secure timer registers on page D1-1592.*
 - *Trapping to EL3 of EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR on page D1-1593.*
 - *Traps to EL3 of all System register accesses to the trace registers on page D1-1594.*
 - *Trapping System register accesses to powerdown debug registers to EL3 on page D1-1595.*
 - *Trapping general System register accesses to debug registers to EL3 on page D1-1596.*
 - *Traps to EL3 of EL2, EL1, and EL0 accesses to Performance Monitors registers on page D1-1597.*

ISS encoding for a IMPLEMENTATION DEFINED exception to EL3

This encoding is used by:

- IMPLEMENTATION DEFINED exception to EL3.

The ISS encoding for these exceptions is:

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

ISS encoding for an exception from an Instruction Abort

This encoding is used by:

- Instruction Abort from a lower Exception level.
Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
- Instruction Abort taken without a change in Exception level.
Used for MMU faults generated by instruction accesses and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

Bits [24:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 FAR is valid.

1 FAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

0 Fault not on a stage 2 translation for a stage 1 translation table walk.

1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

- 000000 Address size fault, level 0 of translation or translation table base register
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000100 Translation fault, level 0
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2
- 000111 Translation fault, level 3
- 001001 Access flag fault, level 1
- 001010 Access flag fault, level 2

| | |
|--------|---|
| 001011 | Access flag fault, level 3 |
| 001101 | Permission fault, level 1 |
| 001110 | Permission fault, level 2 |
| 001111 | Permission fault, level 3 |
| 010000 | Synchronous external abort, not on translation table walk |
| 011000 | Synchronous parity or ECC error on memory access, not on translation table walk |
| 010100 | Synchronous external abort, on translation table walk, level 0 |
| 010101 | Synchronous external abort, on translation table walk, level 1 |
| 010110 | Synchronous external abort, on translation table walk, level 2 |
| 010111 | Synchronous external abort, on translation table walk, level 3 |
| 011100 | Synchronous parity or ECC error on memory access on translation table walk, level 0 |
| 011101 | Synchronous parity or ECC error on memory access on translation table walk, level 1 |
| 011110 | Synchronous parity or ECC error on memory access on translation table walk, level 2 |
| 011111 | Synchronous parity or ECC error on memory access on translation table walk, level 3 |
| 110000 | TLB conflict abort |

All other values are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-5492](#).

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on page D4-1806](#).

———— **Note** —————

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

ISS encoding for an exception from a Data Abort

This encoding is used by:

- Data Abort from a lower Exception level.
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.
- Data Abort taken without a change in Exception level.
Used for MMU faults generated by data accesses, alignment faults other than those caused by the Stack Pointer misalignment, and Synchronous external aborts, including synchronous parity or ECC errors. Not used for debug related exceptions.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0 No valid instruction syndrome. ISS[23:14] are RES0.
- 1 ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults reported in ESR_EL2 except the following stage 2 aborts:

- AArch64 loads and stores of a single general-purpose register (including the register specified with `0b11111`), including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback.
- AArch32 instructions where the instruction:
 - Is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
 - Is not performing register writeback.
 - Is not using R15 as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

ISV is 0 for all faults reported in ESR_EL1 or ESR_EL3.

For ISS reporting, a stage 2 abort on a stage 1 translation table does not return a valid instruction syndrome, and therefore ISV is 0 for these aborts.

The value of ISV on a Synchronous external abort on a stage 2 translation table walk is IMPLEMENTATION DEFINED.

SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

- 00 Byte
- 01 Halfword
- 10 Word
- 11 Doubleword

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

- 0 Sign-extension not required.
- 1 Data item must be sign-extended.

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

SRT, bits [20:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction. If the exception was taken from an Exception level that is using AArch32 then this is the AArch64 view of the register. See [Mapping of the general-purpose registers between the Execution states on page D1-1608](#).

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

SF, bit [15]

Width of the register accessed by the instruction is Sixty-Four. When ISV is 1, the possible values of this bit are:

- 0 Instruction loads/stores a 32-bit wide register.
- 1 Instruction loads/stores a 64-bit wide register.

———— Note ————

This field specifies the register width identified by the instruction, not the Execution state.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

- 0 Instruction did not have acquire/release semantics.
- 1 Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bits [13:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 FAR is valid.
- 1 FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- 0 The Data Abort was not generated by the execution of one of the system instructions identified in the description of value 1.

- 1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The **DC ZVA** instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

- 000000 Address size fault, level 0 of translation or translation table base register
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000100 Translation fault, level 0
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2
- 000111 Translation fault, level 3
- 001001 Access flag fault, level 1
- 001010 Access flag fault, level 2
- 001011 Access flag fault, level 3
- 001101 Permission fault, level 1
- 001110 Permission fault, level 2
- 001111 Permission fault, level 3
- 010000 Synchronous external abort, not on translation table walk
- 011000 Synchronous parity or ECC error on memory access, not on translation table walk
- 010100 Synchronous external abort, on translation table walk, level 0
- 010101 Synchronous external abort, on translation table walk, level 1
- 010110 Synchronous external abort, on translation table walk, level 2
- 010111 Synchronous external abort, on translation table walk, level 3
- 011100 Synchronous parity or ECC error on memory access on translation table walk, level 0
- 011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
- 011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
- 011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
- 100001 Alignment fault
- 110000 TLB conflict abort

- 110100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
- 111101 Section Domain Fault, used only for faults reported in the [PAR_EL1](#)
- 111110 Page Domain Fault, used only for faults reported in the [PAR_EL1](#)

All other values are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-5492.

For more information about the lookup level associated with a fault, see [The level associated with MMU faults](#) on page D4-1806.

Note

Because Access flag faults and Permission faults can only result from a Block or Page translation table descriptor, they cannot occur at level 0.

ISS encoding for an exception from a trapped floating-point exception

This encoding is used by:

- Trapped floating-point exception taken from AArch32 state.
Whether this Exception class is supported is IMPLEMENTATION DEFINED.
- Trapped floating-point exception taken from AArch64 state.
Whether this Exception class is supported is IMPLEMENTATION DEFINED.

The ISS encoding for these exceptions is:

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions. The possible values of this bit are:

- 0 The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
- 1 One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information see [Floating-point exception traps](#) on page D1-1552.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating point exception from a vector instruction.

———— **Note** ————

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from a vector instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Input denormal floating-point exception has not occurred.
- 1 Input denormal floating-point exception occurred during execution of the reported instruction.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Underflow floating-point exception has not occurred.
- 1 Inexact floating-point exception occurred during execution of the reported instruction.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Underflow floating-point exception has not occurred.
- 1 Underflow floating-point exception occurred during execution of the reported instruction.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Overflow floating-point exception has not occurred.
- 1 Overflow floating-point exception occurred during execution of the reported instruction.

DZF, bit [1]

Divide-by-zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- 0 Divide-by-zero floating-point exception has not occurred.
- 1 Divide-by-zero floating-point exception occurred during execution of the reported instruction.

IOE, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

- | | |
|---|---|
| 0 | Invalid Operation floating-point exception has not occurred. |
| 1 | Invalid Operation floating-point exception occurred during execution of the reported instruction. |

In an implementation where the SIMD and floating-point implementation supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the **FPCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the **FPSCR**.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for an SError interrupt

This encoding is used by:

- SError interrupt.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the rest of the syndrome information in this register is valid.

- | | |
|---|--|
| 0 | No valid instruction syndrome. ISS[23:0] are RES0. |
| 1 | ISS[23:0] hold a valid instruction syndrome. |

IS, bits [23:0]

IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError interrupt. Only valid if bit[24] of this register is 1. If bit[24] is 0, this field is RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

This encoding is used by:

- Breakpoint exception from a lower Exception level.
- Breakpoint exception taken without a change in Exception level.
- Vector Catch exception from AArch32 state.

The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.

The ISS encoding for these exceptions is:

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

For more information about generating these exceptions:

- For exceptions from AArch64, see [Breakpoint exceptions on page D2-1641](#).
- For exceptions from AArch32, see [Breakpoint exceptions on page G2-3938](#) and [Vector Catch exceptions on page G2-3975](#).

ISS encoding for an exception from a Software Step exception

This encoding is used by:

- Software Step exception from a lower Exception level.
- Software Step exception taken without a change in Exception level.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

- 0 EX bit is RES0.
- 1 EX bit is valid.

See the EX bit description for more information.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

- 0 An instruction other than a Load-Exclusive instruction was stepped.
- 1 A Load-Exclusive instruction was stepped.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

IFSC, bits [5:0]

Instruction Fault Status Code. This field is set to 0b100010, to indicate a Debug exception.

For more information about generating these exceptions, see [Software Step exceptions on page D2-1673](#).

ISS encoding for an exception from a Watchpoint exception

This encoding is used by:

- Watchpoint exception from a lower Exception level.
- Watchpoint exception taken without a change in Exception level.

The ISS encoding for these exceptions is:

Bits [24:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

- 0 The Data Abort was not generated by the execution of one of the system instructions identified in the description of value 1.
- 1 The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The [DC ZVA](#) instruction is not classified as a cache maintenance instruction, and therefore its execution cannot cause this field to be set to 1.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the abort was caused by a write instruction or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

DFSC, bits [5:0]

Data Fault Status Code. This field is set to `0b100010`, to indicate a Debug exception.

For more information about generating these exceptions, see [Watchpoint exceptions on page D2-1657](#).

ISS encoding for an exception from execution of a Breakpoint instruction

This encoding is used by:

- BKPT instruction execution in AArch32 state.
- BRK instruction execution in AArch64 state.
This is reported in ESR_EL3 only if a BRK instruction is executed at EL3.

The ISS encoding for these exceptions is:

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary. For the AArch32 BKPT instructions, the comment field is described as the immediate field.

For more information about generating these exceptions, see [Breakpoint Instruction exceptions](#) on page D2-1639.

D7.2.28 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Execution at EL0 makes FAR_EL1 become UNKNOWN.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register FAR_EL1[31:0] is architecturally mapped to AArch32 System register [DFAR](#) (NS).

AArch64 System register FAR_EL1[63:32] is architecturally mapped to AArch32 System register [IFAR](#) (NS).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions

The FAR_EL1 bit assignments are:

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment fault exceptions (EC 0x22), and Watchpoint exceptions (EC 0x34 or 0x35). [ESR_EL1](#).EC holds the EC value for the exception.

For a synchronous external abort, if the virtual address that generated the abort was from an address range for which `TCR_ELx.TBI{0,1}==1` for the translation regime in use when the abort was generated, then the top eight bits of the FAR_EL1 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR_EL1.FnV](#) is 0, and the [FAR_EL1](#) is UNKNOWN if [ESR_EL1.FnV](#) is 1.

For all other exceptions taken to EL1, the [FAR_EL1](#) is UNKNOWN.

If a memory fault that sets [FAR_EL1](#) is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates [FAR_EL1](#) is taken from an Exception level that is using AArch32, the top 32 bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xFFFFFFFF. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-1724](#).

———— **Note** —————

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

[FAR_EL1](#) is made UNKNOWN on an exception return from EL1.

Accessing the [FAR_EL1](#):

To access the [FAR_EL1](#):

MRS <Xt>, [FAR_EL1](#) ; Read [FAR_EL1](#) into Xt
MSR [FAR_EL1](#), <Xt> ; Write Xt to [FAR_EL1](#)

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0110 | 0000 | 000 |

D7.2.29 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort, PC alignment fault and Watchpoint exceptions that are taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register [HDFAR](#).

AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register [HIFAR](#).

AArch64 System register FAR_EL2[31:0] is architecturally mapped to AArch32 System register [DFAR](#) (S) when EL2 is implemented.

AArch64 System register FAR_EL2[63:32] is architecturally mapped to AArch32 System register [IFAR](#) (S) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

The FAR_EL2 bit assignments are:

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), PC alignment fault exceptions (EC 0x22), and Watchpoint exceptions (EC 0x34 or 0x35). [ESR_EL2](#).EC holds the EC value for the exception.

For a synchronous external abort, if the virtual address that generated the abort was from an address range for which [TCR_ELx](#).TBI{0,1}==1 for the translation regime in use when the abort was generated, then the top eight bits of the FAR_EL2 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR_EL2](#).FnV is 0, and the FAR_EL2 is UNKNOWN if [ESR_EL2](#).FnV is 1.

For all other exceptions taken to EL2, the FAR_EL2 is UNKNOWN.

If a memory fault that sets FAR_EL2 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL2 is taken from an Exception level that is using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xFFFFFFFF. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-1724](#).

———— **Note** —————

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lower address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL2 is made UNKNOWN on an exception return from EL2.

Accessing the FAR_EL2:

To access the FAR_EL2:

MRS <Xt>, FAR_EL2 ; Read FAR_EL2 into Xt
MSR FAR_EL2, <Xt> ; Write Xt to FAR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0110 | 0000 | 000 |

D7.2.30 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction or Data Abort and PC alignment fault exceptions that are taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Execution at EL2, EL1 or EL0 makes FAR_EL3 become UNKNOWN.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FAR_EL3 is a 64-bit register.

Field descriptions

The FAR_EL3 bit assignments are:

Bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR_EL3 are Instruction Aborts (EC 0x20 or 0x21), Data Aborts (EC 0x24 or 0x25), and PC alignment fault exceptions (EC 0x22). [ESR_EL3](#).EC holds the EC value for the exception.

For a synchronous external abort, if the virtual address that generated the abort was from an address range for which [TCR_ELx](#).TBI{0,1}==1 for the translation regime in use when the abort was generated, then the top eight bits of the FAR_EL3 are UNKNOWN.

For a synchronous external abort other than a synchronous external abort on a translation table walk, this field is valid only if [ESR_EL3](#).FnV is 0, and the FAR_EL3 is UNKNOWN if [ESR_EL3](#).FnV is 1.

For all other exceptions taken to EL3, the FAR_EL3 is UNKNOWN.

If a memory fault that sets FAR_EL3 is generated from a data cache maintenance or DC ZVA instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL3 is taken from an EL using AArch32, the top 32-bits are all zero, unless the faulting address is generated by a load or store instruction that sequentially increments from address 0xffffffff. This is an UNPREDICTABLE condition, and in this case the upper 32-bits are set to 0x00000001.

For a Data Abort or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see [Address tagging in AArch64 state on page D4-1724](#).

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

FAR_EL3 is made UNKNOWN on an exception return from EL3.

Accessing the FAR_EL3:

To access the FAR_EL3:

MRS <Xt>, FAR_EL3 ; Read FAR_EL3 into Xt
MSR FAR_EL3, <Xt> ; Write Xt to FAR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0110 | 0000 | 000 |

D7.2.31 FPEXC32_EL2, Floating-Point Exception Control register

The FPEXC32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register [FPEXC](#) from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [CPTR_EL2.TFP](#)=1, Non-secure accesses to this register from EL2 are trapped to EL2.
- If [CPTR_EL3.TFP](#)=1, accesses to this register from EL2 and EL3 are trapped to EL3.

Configurations

AArch64 System register FPEXC32_EL2 is architecturally mapped to AArch32 System register [FPEXC](#).

If EL1 cannot use AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPEXC32_EL2 is a 32-bit register.

Field descriptions

The FPEXC32_EL2 bit assignments are:

EX, bit [31]

Exception bit. In ARMv8, this bit is RAZ/WI.

EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMRS accesses to the [FPEXC](#) or [FPSID](#).
 - VMRS accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).
- 0 Accesses to the [FPSCR](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.
- 1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR](#).cp10, or, if executing at EL0, [CPACR_EL1](#).FPEN.
- [FPEXC](#).EN.
- If executing in Non-secure state:
 - [HCPTR](#).TCP10, or if EL2 is using AArch64, [CPTR_EL2](#).TFP.
 - [NSACR](#).cp10, or if EL3 is using AArch64, [CPTR_EL3](#).TFP.
- For Advanced SIMD instructions only:
 - [CPACR](#).ASEDIS.
 - If executing in Non-secure state, [HCPTR](#).TASE and [NSACR](#).NSTRCDIS.

See the descriptions of the controls for more information.

———— **Note** —————

When executing at EL0 using AArch32 with EL1 using AArch64, the PE behaves as if the value of [FPEXC](#).EN bit is 1.

DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning TRUE. This field also indicates whether the [FPEXC32_EL2](#).TFV is valid.

The meaning of this bit is:

- 0 The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()`. If [FPEXC32_EL2](#).TFV is RW then it is invalid and UNKNOWN. If [FPEXC32_EL2](#).{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.
- 1 The exception was generated during the execution of an allocated encoding. [FPEXC32_EL2](#).TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the AArch32 [FPSCR](#).{Stride, Len} fields as RAZ, this bit is RES0.

FP2V, bit [28]

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

- 0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of [FPSCR](#).{Stride, Len} was non-zero. If the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.
- 1 FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements [FPSCR](#).{Stride, Len} as RAZ, this bit is RAO/WI.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is RES1.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while [FPSCR](#).IDE was 1:

- 0 Input denormal exception has not occurred.
- 1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when [FPSCR](#).FZ is 1.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while [FPSCR](#).IXE was 1:

- 0 Inexact exception has not occurred.
- 1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

- 0 Underflow exception has not occurred.
- 1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

- 0 Overflow exception has not occurred.
- 1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

DZF, bit [1]

Divide-by-zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:

- 0 Divide-by-zero exception has not occurred.
- 1 Divide-by-zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

IOE, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

- 0 Invalid Operation exception has not occurred.
- 1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

Accessing the FPEXC32_EL2:

To access the FPEXC32_EL2:

MRS <Xt>, FPEXC32_EL2 ; Read FPEXC32_EL2 into Xt
MSR FPEXC32_EL2, <Xt> ; Write Xt to FPEXC32_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0101 | 0011 | 000 |

D7.2.32 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register HACR_EL2 is architecturally mapped to AArch32 System register [HACR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACR_EL2 is a 32-bit register.

Field descriptions

The HACR_EL2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACR_EL2:

To access the HACR_EL2:

MRS <Xt>, HACR_EL2 ; Read HACR_EL2 into Xt
MSR HACR_EL2, <Xt> ; Write Xt to HACR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0001 | 111 |

D7.2.33 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register HCR_EL2[31:0] is architecturally mapped to AArch32 System register [HCR](#).

AArch64 System register HCR_EL2[63:32] is architecturally mapped to AArch32 System register [HCR2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions

The HCR_EL2 bit assignments are:

Bits [63:39]

Reserved, RES0.

MIOCNCEN, bit [38]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure EL1&0 translation regime.

- 0 For the Non-secure EL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.
- 1 For the Non-secure EL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see [Mismatched memory attributes on page B2-105](#).

This field can be implemented as RAZ/WI.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

Bits [37:34]

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction access cacheability disable. For the Non-secure EL1&0 translation regime, when `HCR_EL2.VM==1`, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

- 0 This control has no effect on stage 2 of the Non-secure EL1&0 translation regime.
- 1 For the Non-secure EL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

This bit has no effect on the EL2 or EL3 translation regimes.

CD, bit [32]

Stage 2 Data access cacheability disable. For the Non-secure EL1&0 translation regime, when `HCR_EL2.VM==1`, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

- 0 This control has no effect on stage 2 of the Non-secure EL1&0 translation regime for data accesses and translation table walks.
- 1 For the Non-secure EL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

This bit has no effect on the EL2 or EL3 translation regimes.

RW, bit [31]

Execution state control for lower Exception levels:

- 0 Lower levels are all AArch32.
- 1 The Execution state for EL1 is AArch64. The Execution state for EL0 is determined by the current value of `PSTATE.nRW` when executing at EL0.

If all lower Exception levels cannot use AArch32 then this bit is RAO/WI.

In an implementation that includes EL3, when `SCR_EL3.NS`==0, the PE behaves as if this bit has the same value as the `SCR_EL3.RW` bit for all purposes other than a direct read or write access of `HCR_EL2`.

The RW bit is permitted to be cached in a TLB.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to EL2, from both Execution states. The registers for which read accesses are trapped are as follows:

Non-secure EL1 using AArch64: `SCTLR_EL1`, `TTBR0_EL1`, `TTBR1_EL1`, `TCR_EL1`, `ESR_EL1`, `FAR_EL1`, `AFSR0_EL1`, `AFSR1_EL1`, `MAIR_EL1`, `AMAIR_EL1`, `CONTEXTIDR_EL1`.

Non-secure EL1 using AArch32: `SCTLR`, `TTBR0`, `TTBR1`, `TTBCR`, `DACR`, `DFSR`, `IFSR`, `DFAR`, `IFAR`, `ADFSR`, `AIFSR`, `PRRR`, `NMRR`, `MAIR0`, `MAIR1`, `AMAIR0`, `AMAIR1`, `CONTEXTIDR`.

- | | |
|---|---|
| 0 | This control has no effect on Non-secure EL1 read accesses to Virtual Memory controls. |
| 1 | Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to EL2. |

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

HCD, bit [29]

HVC instruction disable. Disables Non-secure state execution of HVC instructions, from both Execution states.

- | | |
|---|---|
| 0 | HVC instruction execution is enabled at EL2 and Non-secure EL1. |
| 1 | HVC instructions are UNDEFINED at EL2 and Non-secure EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed. |

————— **Note** —————

HVC instructions are always UNDEFINED at EL0.

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

TDZ, bit [28]

Trap `DC ZVA` instructions. Traps Non-secure EL0 and EL1 execution of `DC ZVA` instructions to EL2, from AArch64 state only.

- | | |
|---|--|
| 0 | This control has no effect on the Non-secure EL0 and EL1 execution of <code>DC ZVA</code> instructions. |
| 1 | In AArch64 state, any attempt to execute a <code>DC ZVA</code> instruction at Non-secure EL1, or at Non-secure EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2. Reading the <code>DCZID_EL0</code> returns a value that indicates that <code>DC ZVA</code> instructions are not supported. |

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

TGE, bit [27]

Trap General Exceptions, from Non-secure EL0.

- | | |
|---|--|
| 0 | This control has no effect on execution at EL0. |
| 1 | When the value of <code>SCR_EL3.NS</code> is 0, this control has no effect on execution at EL0. When the value of <code>SCR_EL3.NS</code> is 1, then: <ul style="list-style-type: none"> • All exceptions that would be routed to EL1 are routed to EL2. • The <code>SCTLR_EL1.M</code> field, or the <code>SCTLR.M</code> field if EL1 is using AArch32, is treated as being 0 for all purposes other than returning the result of a direct read of <code>SCTLR_EL1</code> or <code>SCTLR</code>. |

- The HCR_EL2.{FMO, IMO, AMO} fields are treated as being 1 for all purposes other than a direct read or write access of HCR_EL2.
- All virtual interrupts are disabled.
- Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
- An exception return to EL1 is treated as an illegal exception return.
- The MDCR_EL2.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of MDCR_EL2.

HCR_EL2.TGE must not be cached in a TLB.

In an implementation that includes EL3, when the value of SCR_EL3.NS is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR_EL2.

TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to EL2, from both Execution states. The registers for which write accesses are trapped are as follows:

Non-secure EL1 using AArch64: SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, CONTEXTIDR_EL1.

Non-secure EL1 using AArch32: SCTLR, TTBR0, TTBR1, TTBCR, DACR, DFSR, IFSR, DFAR, IFAR, ADFSAR, AIFSAR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, CONTEXTIDR.

- | | |
|---|---|
| 0 | This control has no effect on Non-secure EL1 write accesses to EL1 virtual memory control registers. |
| 1 | Non-secure EL1 write accesses to the specified EL1 virtual memory control registers are trapped to EL2. |

In an implementation that includes EL3, when the value of SCR_EL3.NS is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR_EL2.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of TLB maintenance instructions to EL2, from both Execution states. This applies to the following instructions:

Non-secure EL1 using AArch64: TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, TLBI VAALE1IS, TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, TLBI VAALE1.

Non-secure EL1 using AArch32: TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAIS, TLBIMVALIS, TLBIMVAALIS, ITLBIALL, ITLBIIMVA, ITLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, TLBIALL, TLBIMVA, TLBIASID, TLBIMVAA, TLBIMVAL, TLBIMVAAL

- | | |
|---|--|
| 0 | This control has no effect on Non-secure EL1 execution of TLB maintenance instructions. |
| 1 | Non-secure EL1 execution of the specified TLB maintenance instructions are trapped to EL2. |

In an implementation that includes EL3, when the value of SCR_EL3.NS is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of HCR_EL2.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at Non-secure EL1 or EL0 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64: IC IVAU, DC CVAU. However, if the value of SCTLR_EL1.UCI is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

Non-secure EL1 using AArch64: IC IVAU, IC IALLU, IC IALLUIS, DC CVAU.

Non-secure EL1 using AArch32: [ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), [DCCMVAU](#).

———— **Note** ————

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [IC IALLUIS](#) and [IC IALLU](#) are always UNDEFINED at EL0 using AArch64.
- [ICIMVAU](#), [ICIALLU](#), [ICIALLUIS](#), and [DCCMVAU](#) are always UNDEFINED at EL0 using AArch32.

0 This control has no effect on the execution of cache maintenance instructions.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TPC, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps execution of those cache maintenance instructions at Non-secure EL1 or EL0 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL0 using AArch64: [DC CIVAC](#), [DC CVAC](#). However, if the value of [SCTLR_EL1.UCI](#) is 0 these instructions are UNDEFINED at EL0 and any resulting exception is higher priority than this trap to EL2.

Non-secure EL1 using AArch64: [DC IVAC](#), [DC CIVAC](#), [DC CVAC](#).

Non-secure EL1 using AArch32: [DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

———— **Note** ————

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- [DC IVAC](#) is always UNDEFINED at EL0 using AArch64.
- [DCIMVAC](#), [DCCIMVAC](#), and [DCCMVAC](#) are always UNDEFINED at EL0 using AArch32.

0 This control has no effect on the execution of cache maintenance instructions.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at Non-secure EL1 using AArch64, and at Non-secure EL1 using AArch32, to EL2. This applies to the following instructions:

Non-secure EL1 using AArch64: [DC ISW](#), [DC CSW](#), [DC CISW](#).

Non-secure EL1 using AArch32: [DCISW](#), [DCCSW](#), [DCCISW](#).

———— **Note** ————

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

0 This control has no effect on the execution of cache maintenance instructions.

1 Non-secure execution of the specified instructions is trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TACR, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to EL2, from both Execution states. This applies to the following register accesses:

- Non-secure EL1 using AArch64: [ACTLR_EL1](#).
 - Non-secure EL1 using AArch32: [ACTLR](#) and, if implemented, [ACTLR2](#).
- 0 This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.
- 1 Non-secure EL1 accesses to the specified registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2. This applies to the following register accesses:

AArch64: The following reserved encoding spaces:

- IMPLEMENTATION DEFINED system instructions, which are accessed using [SYS](#) and [SYSL](#), with $CRn == \{11, 15\}$.
- IMPLEMENTATION DEFINED System registers, which are accessed using [MRS](#) and [MSR](#) with the [S3_<op1>_<Cn>_<Cm>_<op2>](#) register name.

AArch32: MCR and MRC instructions accessing the following encodings:

- All coproc==p15, $CRn==c9$, $opc1 == \{0-7\}$, $CRm == \{c0-c2, c5-c8\}$, $opc2 == \{0-7\}$.
- All coproc==p15, $CRn==c10$, $opc1 == \{0-7\}$, $CRm == \{c0, c1, c4, c8\}$, $opc2 == \{0-7\}$.
- All coproc==p15, $CRn==c11$, $opc1==\{0-7\}$, $CRm == \{c0-c8, c15\}$, $opc2 == \{0-7\}$.

When the value of [HCR_EL2.TIDCP](#) is 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to EL2. If it is not, then it is UNDEFINED, and any attempt to access it from Non-secure EL0 generates an exception that is taken to EL1.

- 0 This control has no effect on the encodings reserved for IMPLEMENTATION DEFINED functionality.
- 1 Non-secure EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to EL2, from both Execution states.

- 0 This control has no effect on the execution of SMC instructions.
- 1 Any attempt to execute an SMC instruction at Non-secure EL1 using AArch64 or Non-secure EL1 using AArch32 is trapped to EL2, regardless of the value of [SCR_EL3.SMD](#).

In AArch32 state, the ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

If EL3 is not implemented, this bit is RES0.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TID3, bit [18]

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to EL2:

AArch64: [ID_PFR0_EL1](#), [ID_PFR1_EL1](#), [ID_DFR0_EL1](#), [ID_AFR0_EL1](#), [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), [ID_ISAR5_EL1](#), [MVFR0_EL1](#), [MVFR1_EL1](#), [MVFR2_EL1](#), [ID_AA64PFR0_EL1](#), [ID_AA64PFR1_EL1](#), [ID_AA64DFR0_EL1](#), [ID_AA64DFR1_EL1](#), [ID_AA64ISAR0_EL1](#), [ID_AA64ISAR1_EL1](#), [ID_AA64MMFR0_EL1](#), [ID_AA64MMFR1_EL1](#), [ID_AA64AFR0_EL1](#), [ID_AA64AFR1_EL1](#), and [ID_MMFR4_EL1](#), except that if [ID_MMFR4_EL1](#) is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to [ID_MMFR4_EL1](#) are trapped.

It is IMPLEMENTATION DEFINED whether this field traps MRS accesses to encodings in the following range that are not already mentioned in this field description:

- Op0 == 3, op1 == 0, CRn == c0, CRm == {c2-c7}, op2 == {0-7}.

AArch32: [ID_PFR0](#), [ID_PFR1](#), [ID_DFR0](#), [ID_AFR0](#), [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), [ID_ISAR5](#), [MVFR0](#), [MVFR1](#), [MVFR2](#), and [ID_MMFR4](#), except that if [ID_MMFR4](#) is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to [ID_MMFR4](#) are trapped.

MRC access to any of the following encodings are also trapped:

- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.

0 This control has no effect on Non-secure EL1 reads of the ID group 3 registers.

1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2:

AArch64:

- Non-secure EL1 reads of [CTR_EL0](#), [CCSIDR_EL1](#), [CLIDR_EL1](#), and [CSSELR_EL1](#).
- Non-secure EL0 reads of [CTR_EL0](#), except that if the value of [SCTLR_EL1.UCT](#) is 0 then EL0 reads of [CTR_EL0](#) are UNDEFINED and any resulting exception takes precedence over this trap.
- Non-secure EL1 writes to [CSSELR_EL1](#).

AArch32:

- Non-secure EL1 reads of the [CTR](#), [CCSIDR](#), [CLIDR](#), and [CSSELR](#).
- Non-secure EL1 writes to the [CSSELR](#).

0 This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.

1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers are trapped to EL2:

AArch64: [REVIDR_EL1](#), [AIDR_EL1](#).

AArch32: [TCMTR](#), [TLBTR](#), [REVIDR](#), [AIDR](#).

- 0 This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TID0, bit [15]

Trap ID group 0. Traps the following register accesses to EL2:

AArch64: None.

AArch32:

- Non-secure EL1 reads of the [JIDR](#).
- If the [JIDR](#) is RAZ from Non-secure EL0, Non-secure EL0 of the [JIDR](#).
- Non-secure EL1 reads of the [FPSID](#).

Note

- It is IMPLEMENTATION DEFINED whether the [JIDR](#) is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then any resulting exception takes precedence over this trap.
- The [FPSID](#) is not accessible at EL0 using AArch32.
- Writes to the [FPSID](#) are ignored, and not trapped by this control.

- 0 This control has no effect on Non-secure EL1 reads of the ID group 0 registers.
1 The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to EL2.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

TWE, bit [14]

Traps Non-secure EL0 and EL1 execution of WFE instructions to EL2, from both Execution states.

- 0 This control has no effect on the execution of WFE instructions at Non-secure EL0 or Non-secure EL1.
1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state, except that when the value of [SCTLR_EL1.nTWE](#) is 0, the trap of EL0 execution to EL1 takes precedence over this trap.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

Note

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

TWI, bit [13]

Traps Non-secure EL0 and EL1 execution of WFI instructions to EL2, from both Execution states.

- 0 This control has no effect on the execution of WFI instructions at Non-secure EL1 or Non-secure EL0.

- 1 Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to EL2, if the instruction would otherwise have caused the PE to enter a low-power state, except that when the value of [SCTLR_EL1.nTWI](#) is 0, the trap of EL0 execution to EL1 takes precedence over this trap.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

———— **Note** ————

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

DC, bit [12]

Default Cacheability.

- 0 This control has no effect on the Non-secure EL1&0 translation regime.
- 1 In Non-secure state:
- When EL1 is using AArch64, the PE behaves as if the value of the [SCTLR_EL1.M](#) field is 0 for all purposes other than returning the value of a direct read of [SCTLR_EL1](#).
 - When EL1 is using AArch32, the PE behaves as if the value of the [SCTLR.M](#) field is 0 for all purposes other than returning the value of a direct read of [SCTLR](#).
 - The PE behaves as if the value of the [HCR_EL2.VM](#) field is 1 for all purposes other than returning the value of a direct read of [HCR_EL2](#).
 - The memory type produced by stage 1 of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2 and EL3 translation regimes.

This field is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

- 00 No effect
- 01 Inner Shareable
- 10 Outer Shareable
- 11 Full system

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

AArch32: [BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

AArch64: [TLBI VMALLE1](#), [TLBI VAE1](#), [TLBI ASIDE1](#), [TLBI VAAE1](#), [TLBI VALE1](#), [TLBI VAALE1](#), [IC IALLU](#).

- 0 This field has no effect on the operation of the specified instructions.
- 1 When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

VSE, bit [8]

Virtual SError interrupt.

- 0 This mechanism is not making a virtual SError interrupt pending.
- 1 A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is only enabled when the value of [HCR_EL2](#).{TGE, AMO} is {0, 1}.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

VI, bit [7]

Virtual IRQ Interrupt.

- 0 This mechanism is not making a virtual IRQ pending.
- 1 A virtual IRQ is pending because of this mechanism.

The virtual IRQ is only enabled when the value of [HCR_EL2](#).{TGE, IMO} is {0, 1}.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

VF, bit [6]

Virtual FIQ Interrupt.

- 0 This mechanism is not making a virtual FIQ pending.
- 1 A virtual FIQ is pending because of this mechanism.

The virtual FIQ is only enabled when the value of [HCR_EL2](#).{TGE, FMO} is {0, 1}.

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

AMO, bit [5]

Physical SError Interrupt routing.

- 0 When executing at Non-secure Exception levels below EL2, physical SError Interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical SError Interrupts are not taken unless they are routed to EL3 by the [SCR_EL3.EA](#) bit.
Virtual SError interrupts are disabled.
- 1 When executing at any Exception level in Non-secure state:
- Physical SError interrupts are taken to EL2 unless they are routed to EL3.
 - If [HCR_EL2.TGE](#)==0 then Virtual SError interrupts are enabled in the Non-secure state.

If the value of [HCR_EL2.TGE](#) is 1, then in Non-secure state the [HCR_EL2.AMO](#) bit behaves as 1 for all purposes other than a direct read of the value of the bit.

For more information, see [Asynchronous exception routing on page D1-1556](#).

In an implementation that includes EL3, when the value of [SCR_EL3.NS](#) is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of [HCR_EL2](#).

IMO, bit [4]

Physical IRQ Routing.

- 0 When executing at Non-secure Exception levels below EL2, physical IRQ interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical IRQ interrupts are not taken unless they are routed to EL3 by the [SCR_EL3.IRQ](#) bit.
Virtual IRQ interrupts are disabled.
- 1 When executing at any Exception level in Non-secure state:
- Physical IRQ interrupts are taken to EL2 unless they are routed to EL3.
 - If `HCR_EL2.TGE==0` then Virtual IRQ interrupts are enabled in Non-secure state.

If the value of `HCR_EL2.TGE` is 1, then in Non-secure state the `HCR_EL2.IMO` bit behaves as 1 for all purposes other than a direct read of the value of the bit.

For more information, see [Asynchronous exception routing](#) on page D1-1556.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

FMO, bit [3]

Physical FIQ Routing.

- 0 When executing at Non-secure Exception levels below EL2, physical FIQ interrupts are not taken to EL2.
When executing at EL2 using AArch64, physical FIQ interrupts are not taken unless they are routed to EL3 by the [SCR_EL3.FIQ](#) bit.
Virtual FIQ interrupts are disabled.
- 1 When executing at any Exception level in Non-secure state:
- Physical FIQ interrupts are taken to EL2 unless they are routed to EL3.
 - If `HCR_EL2.TGE==0` then Virtual FIQ interrupts are enabled in Non-secure state.

If the value of `HCR_EL2.TGE` is 1, then in Non-secure state the `HCR_EL2.FMO` bit behaves as 1 for all purposes other than a direct read of the value of the bit.

For more information, see [Asynchronous exception routing](#) on page D1-1556.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

PTW, bit [2]

Protected Table Walk. In the Non-secure EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

- 0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
- 1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of `SCR_EL3.NS` is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of `HCR_EL2`.

SWIO, bit [1]

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to be treated as data cache clean and invalidate by set/way:

- 0 This control has no effect on the operation of data cache invalidate by set/way instructions.

1 Data cache invalidate by set/way instructions operate as data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: **DCISW** is executed as **DCCISW**.

AArch64: **DC ISW** is executed as **DC CISW**.

This bit can be implemented as RES1.

In an implementation that includes EL3, when the value of **SCR_EL3.NS** is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of **HCR_EL2**.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime. Possible values of this bit are:

0 Non-secure EL1&0 stage 2 address translation disabled.

1 Non-secure EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 operate as data cache clean and invalidate instructions. For the invalidate by set/way instruction this behavior applies regardless of the value of the **HCR_EL2.SWIO** bit.

This bit is permitted to be cached in a TLB.

In an implementation that includes EL3, when the value of **SCR_EL3.NS** is 0 the PE behaves as if this field is 0 for all purposes other than a direct read or write access of **HCR_EL2**.

Accessing the HCR_EL2:

To access the **HCR_EL2**:

MRS <Xt>, HCR_EL2 ; Read HCR_EL2 into Xt
MSR HCR_EL2, <Xt> ; Write Xt to HCR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0001 | 000 |

D7.2.34 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register HPFAR_EL2[31:0] is architecturally mapped to AArch32 System register [HPFAR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

The HPFAR_EL2 bit assignments are:

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

Bits [63:40]

Reserved, RES0.

FIPA[47:12], bits [39:4]

Bits [47:12] of the faulting intermediate physical address. For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

The HPFAR_EL2 is written for:

- Translation or Access faults in the second stage of translation.
- An abort in the second stage of translation performed during the translation table walk of a first stage translation, caused by a Translation fault, an Access flag fault, or a Permission fault.
- A stage 2 Address size fault.

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the instruction or data abort. It is the lowest address that gave rise to the fault. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores a mis-aligned address that crosses a page boundary, the architecture does not prioritize between those different faults.

For all other exceptions taken to EL2, this register is UNKNOWN.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR_EL2:

To access the HPFAR_EL2:

MRS <Xt>, HPFAR_EL2 ; Read HPFAR_EL2 into Xt
MSR HPFAR_EL2, <Xt> ; Write Xt to HPFAR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0110 | 0000 | 100 |

D7.2.35 HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

Purpose

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower in AArch32, to the System register in the coproc == 1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register HSTR_EL2 is architecturally mapped to AArch32 System register [HSTR](#).

If EL2 is not implemented, this register is RES0 from EL3.

If no Exception level can use AArch32, then this register is RES0

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSTR_EL2 is a 32-bit register.

Field descriptions

The HSTR_EL2 bit assignments are:

Bits [31:16]

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Fields T14 and T4 are RES0.

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 1111 encoding space are trapped to Hyp mode:

0 This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

- 1 Any Non-secure EL1 MCR, MRC access with coproc == 1111 and CRn == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.
Any Non-secure EL1 MCRR, MRRC access with coproc == 1111 and CRm == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR_EL2.T7 is 1:

- Any 32-bit access from a Non-secure EL1 mode, using an MCR or MRC instruction with coproc set to 1111 and <CRn> set to c7, and that is not UNDEFINED when HSTR_EL2.T7 is 0, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure EL1 mode, using an MCRR or MRRC instruction with coproc set to 1111 and <CRm> set to c7, and that is not UNDEFINED when HSTR_EL2.T7 is 0, is trapped to Hyp mode.

Accessing the HSTR_EL2:

To access the HSTR_EL2:

MRS <Xt>, HSTR_EL2 ; Read HSTR_EL2 into Xt
MSR HSTR_EL2, <Xt> ; Write Xt to HSTR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0001 | 011 |

D7.2.36 ID_AA64AFR0_EL1, AArch64 Auxiliary Feature Register 0

The ID_AA64AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64AFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64AFR0_EL1 bit assignments are:

Bits [63:32]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [31:28]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [27:24]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [23:20]

IMPLEMENTATION DEFINED, bits [15:12]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [11:8]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [7:4]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [3:0]

IMPLEMENTATION DEFINED.

Accessing the ID_AA64AFR0_EL1:

To access the ID_AA64AFR0_EL1:

MRS <Xt>, ID_AA64AFR0_EL1 ; Read ID_AA64AFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0101 | 100 |

D7.2.37 ID_AA64AFR1_EL1, AArch64 Auxiliary Feature Register 1

The ID_AA64AFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about the IMPLEMENTATION DEFINED features of the PE in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64AFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64AFR1_EL1 bit assignments are:

Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64AFR1_EL1:

To access the ID_AA64AFR1_EL1:

MRS <Xt>, ID_AA64AFR1_EL1 ; Read ID_AA64AFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0101 | 101 |

D7.2.38 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top level information about the debug system in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

The external register [EDDFR](#) gives information from this register.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR0_EL1 bit assignments are:

Bits [63:32]

Reserved, RES0.

CTX_CMPs, bits [31:28]

Number of breakpoints that are context-aware, minus 1. These are the highest numbered breakpoints.

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1. The value of 0b0000 is reserved.

Bits [19:16]

Reserved, RES0.

BRPs, bits [15:12]

Number of breakpoints, minus 1. The value of 0b0000 is reserved.

PMUVer, bits [11:8]

Performance Monitors Extension version. Indicates whether System register interface to Performance Monitors extension is implemented. Defined values are:

- 0000 Performance Monitors Extension System registers not implemented.
- 0001 Performance Monitors Extension System registers implemented, PMUv3.
- 1111 IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported.

All other values are reserved.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace macrocell is implemented. Defined values are:

- 0000 Trace macrocell System registers not implemented.
- 0001 Trace macrocell System registers implemented.

All other values are reserved.

A value of 0b0000 only indicates that no System register interface to a trace macrocell is implemented. A trace macrocell might nevertheless be implemented without a System register interface.

DebugVer, bits [3:0]

Debug architecture version. Indicates presence of ARMv8 debug architecture.

- 0110 ARMv8 debug architecture.

All other values are reserved.

Accessing the ID_AA64DFR0_EL1:

To access the ID_AA64DFR0_EL1:

MRS <Xt>, ID_AA64DFR0_EL1 ; Read ID_AA64DFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0101 | 000 |

D7.2.39 ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of top level information about the debug system in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64DFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64DFR1_EL1 bit assignments are:

Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64DFR1_EL1:

To access the ID_AA64DFR1_EL1:

MRS <Xt>, ID_AA64DFR1_EL1 ; Read ID_AA64DFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0101 | 001 |

D7.2.40 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR0_EL1 bit assignments are:

Bits [63:20]

Reserved, RES0.

CRC32, bits [19:16]

CRC32 instructions in AArch64. Defined values are:

0000 No CRC32 instructions implemented.

0001 CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX instructions implemented.

All other values are reserved.

SHA2, bits [15:12]

SHA2 instructions in AArch64. Defined values are:

0000 No SHA2 instructions implemented.

0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 instructions implemented.

All other values are reserved.

SHA1, bits [11:8]

SHA1 instructions in AArch64. Defined values are:

0000 No SHA1 instructions implemented.

0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 instructions implemented.

All other values are reserved.

AES, bits [7:4]

AES instructions in AArch64. Defined values are:

0000 No AES instructions implemented.

0001 AESE, AESD, AESMC, and AESIMC instructions implemented.

0010 As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

Bits [3:0]

Reserved, RES0.

Accessing the ID_AA64ISAR0_EL1:

To access the ID_AA64ISAR0_EL1:

MRS <Xt>, ID_AA64ISAR0_EL1 ; Read ID_AA64ISAR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0110 | 000 |

D7.2.41 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64ISAR1_EL1 bit assignments are:

Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64ISAR1_EL1:

To access the ID_AA64ISAR1_EL1:

MRS <Xt>, ID_AA64ISAR1_EL1 ; Read ID_AA64ISAR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0110 | 001 |

D7.2.42 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR0_EL1 bit assignments are:

Bits [63:32]

Reserved, RES0.

TGran4, bits [31:28]

Support for 4KB memory translation granule size. Defined values are:

- 0000 4KB granule supported.
 - 1111 4KB granule not supported.
- All other values are reserved.

TGran64, bits [27:24]

Support for 64KB memory translation granule size. Defined values are:

- 0000 64KB granule supported.
 - 1111 64KB granule not supported.
- All other values are reserved.

TGran16, bits [23:20]

Support for 16KB memory translation granule size. Defined values are:

0000 16KB granule not supported.

0001 16KB granule supported.

All other values are reserved.

BigEndEL0, bits [19:16]

Mixed-endian support at EL0 only. Defined values are:

0000 No mixed-endian support at EL0. The [SCTLR_EL1.EOE](#) bit has a fixed value.

0001 Mixed-endian support at EL0. The [SCTLR_EL1.EOE](#) bit can be configured.

All other values are reserved.

This field is invalid and is RES0 if the BigEnd field, bits [11:8], is not 0000.

SNSMem, bits [15:12]

Secure versus Non-secure Memory distinction. Defined values are:

0000 Does not support a distinction between Secure and Non-secure Memory.

0001 Does support a distinction between Secure and Non-secure Memory.

All other values are reserved.

BigEnd, bits [11:8]

Mixed-endian configuration support. Defined values are:

0000 No mixed-endian support. The [SCTLR_ELx.EE](#) bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.

0001 Mixed-endian support. The [SCTLR_ELx.EE](#) and [SCTLR_EL1.EOE](#) bits can be configured.

All other values are reserved.

ASIDBits, bits [7:4]

Number of ASID bits. Defined values are:

0000 8 bits.

0010 16 bits.

All other values are reserved.

PARange, bits [3:0]

Physical Address range supported. Defined values are:

0000 32 bits, 4GB.

0001 36 bits, 64GB.

0010 40 bits, 1TB.

0011 42 bits, 4TB.

0100 44 bits, 16TB.

0101 48 bits, 256TB.

All other values are reserved.

Accessing the ID_AA64MMFR0_EL1:

To access the ID_AA64MMFR0_EL1:

MRS <Xt>, ID_AA64MMFR0_EL1 ; Read ID_AA64MMFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0111 | 000 |

D7.2.43 ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of the information about the implemented memory model and memory management support in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64MMFR1_EL1 bit assignments are:

Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64MMFR1_EL1:

To access the ID_AA64MMFR1_EL1:

MRS <Xt>, ID_AA64MMFR1_EL1 ; Read ID_AA64MMFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0111 | 001 |

D7.2.44 ID_AA64PFR0_EL1, AArch64 Processor Feature Register 0

The ID_AA64PFR0_EL1 characteristics are:

Purpose

Provides additional information about implemented PE features in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| ELO | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

The external register [EDPFR](#) gives information from this register.

Attributes

ID_AA64PFR0_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR0_EL1 bit assignments are:

Bits [63:28]

Reserved, RES0.

GIC, bits [27:24]

System register GIC interface support. Defined values are:

0000 No System register interface to the GIC is supported.

0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

AdvSIMD, bits [23:20]

Advanced SIMD. Defined values are:

0000 Advanced SIMD is implemented.

1111 Advanced SIMD is not implemented.

All other values are reserved.

This field must have the same value as the FP field.

FP, bits [19:16]

Floating-point. Defined values are:

0000 Floating-point is implemented.

1111 Floating-point is not implemented.

All other values are reserved.

This field must have the same value as the AdvSIMD field.

EL3, bits [15:12]

EL3 Exception level handling. Defined values are:

0000 EL3 is not implemented.

0001 EL3 can be executed in AArch64 state only.

0010 EL3 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL2, bits [11:8]

EL2 Exception level handling. Defined values are:

0000 EL2 is not implemented.

0001 EL2 can be executed in AArch64 state only.

0010 EL2 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL1, bits [7:4]

EL1 Exception level handling. Defined values are:

0001 EL1 can be executed in AArch64 state only.

0010 EL1 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

EL0, bits [3:0]

EL0 Exception level handling. Defined values are:

0001 EL0 can be executed in AArch64 state only.

0010 EL0 can be executed in either AArch64 or AArch32 state.

All other values are reserved.

Accessing the ID_AA64PFR0_EL1:

To access the ID_AA64PFR0_EL1:

MRS <Xt>, ID_AA64PFR0_EL1 ; Read ID_AA64PFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0100 | 000 |

D7.2.45 ID_AA64PFR1_EL1, AArch64 Processor Feature Register 1

The ID_AA64PFR1_EL1 characteristics are:

Purpose

Reserved for future expansion of information about implemented PE features in AArch64.

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ID_AA64PFR1_EL1 is a 64-bit register.

Field descriptions

The ID_AA64PFR1_EL1 bit assignments are:

Bits [63:0]

Reserved, RES0.

Accessing the ID_AA64PFR1_EL1:

To access the ID_AA64PFR1_EL1:

MRS <Xt>, ID_AA64PFR1_EL1 ; Read ID_AA64PFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0100 | 001 |

D7.2.46 ID_AFR0_EL1, AArch32 Auxiliary Feature Register 0

The ID_AFR0_EL1 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32.

Must be interpreted with the Main ID Register, [MIDR_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_AFR0_EL1 is architecturally mapped to AArch32 System register [ID_AFR0](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_AFR0_EL1 is a 32-bit register.

Field descriptions

The ID_AFR0_EL1 bit assignments are:

Bits [31:16]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [15:12]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [11:8]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [7:4]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [3:0]

IMPLEMENTATION DEFINED.

Accessing the ID_AFR0_EL1:

To access the ID_AFR0_EL1:

MRS <Xt>, ID_AFR0_EL1 ; Read ID_AFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 011 |

D7.2.47 ID_DFR0_EL1, AArch32 Debug Feature Register 0

The ID_DFR0_EL1 characteristics are:

Purpose

Provides top level information about the debug system in AArch32.

Must be interpreted with the Main ID Register, [MIDR_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_DFR0_EL1 is architecturally mapped to AArch32 System register [ID_DFR0](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_DFR0_EL1 is a 32-bit register.

Field descriptions

The ID_DFR0_EL1 bit assignments are:

| | | | | | | | | |
|------|---------|----------|---------|--------|---------|---------|--------|---|
| 31 | 28 27 | 24 23 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| RES0 | PerfMon | MProfDbg | MMapTrc | CopTrc | MMapDbg | CopSDBG | CopDbg | |

Bits [31:28]

Reserved, RES0.

PerfMon, bits [27:24]

Performance Monitors. Support for System registers-based ARM Performance Monitors Extension, using registers in the coproc == 1111 encoding space, for A and R profile processors. Defined values are:

| | |
|------|--|
| 0000 | Performance Monitors Extension System registers not implemented. |
| 0001 | Support for Performance Monitors Extension version 1 (PMUv1) System registers. |
| 0010 | Support for Performance Monitors Extension version 2 (PMUv2) System registers. |
| 0011 | Support for Performance Monitors Extension version 3 (PMUv3) System registers. |
| 1111 | IMPLEMENTATION DEFINED form of Performance Monitors System registers supported. PMUv3 not supported. |

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0011, and 1111.

In ARMv7, the value 0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

MProfDbg, bits [23:20]

M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:

0000 Not supported.

0001 Support for M profile Debug architecture, with memory-mapped access.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

MMapTrc, bits [19:16]

Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:

0000 Not supported.

0001 Support for ARM trace architecture, with memory-mapped access.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]

Support for System registers-based trace model, using registers in the coproc == 1110 encoding space. Defined values are:

0000 Not supported.

0001 Support for ARM trace architecture, with System registers access.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]

Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.

In ARMv8-A this field is RES0.

The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSDBG, bits [7:4]

Support for a System registers-based Secure debug model, using registers in the coproc = 1110 encoding space, for an A profile processor that includes EL3.

If EL3 is not implemented and the implemented Security state is Non-Secure state, this field is RES0. Otherwise, this field reads the same as bits [3:0].

CopDbg, bits [3:0]

Support for System registers-based debug model, using registers in the coproc == 1110 encoding space, for A and R profile processors. Defined values are:

0000 Not supported.

0010 Support for ARMv6, v6 Debug architecture, with System registers access.

0011 Support for ARMv6, v6.1 Debug architecture, with System registers access.

0100 Support for ARMv7, v7 Debug architecture, with System registers access.

0101 Support for ARMv7, v7.1 Debug architecture, with System registers access.

0110 Support for ARMv8 debug architecture, with System registers access.

All other values are reserved.

In ARMv8-A the permitted values are 0000, and 0110.

Accessing the ID_DFR0_EL1:

To access the ID_DFR0_EL1:

MRS <Xt>, ID_DFR0_EL1 ; Read ID_DFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 010 |

D7.2.48 ID_ISAR0_EL1, AArch32 Instruction Set Attribute Register 0

The ID_ISAR0_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR0_EL1 is architecturally mapped to AArch32 System register [ID_ISAR0](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR0_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR0_EL1 bit assignments are:

| | | | | | | | | |
|------|--------|-------|---------|-----------|----------|----------|------|---|
| 31 | 28 27 | 24 23 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| RES0 | Divide | Debug | Coprocc | CmpBranch | BitField | BitCount | Swap | |

Bits [31:28]

Reserved, RES0.

Divide, bits [27:24]

Indicates the implemented Divide instructions. Defined values are:

0000 None implemented.

0001 Adds SDIV and UDIV in the T32 instruction set.

0010 As for 0001, and adds SDIV and UDIV in the A32 instruction set.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Debug, bits [23:20]

Indicates the implemented Debug instructions. Defined values are:

0000 None implemented.

0001 Adds BKPT.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Coproc, bits [19:16]

Indicates the implemented System register access instructions. Defined values are:

0000 None implemented, except for instructions separately attributed by the architecture to provide access to AArch32 System registers and System instructions.

0001 Adds generic CDP, LDC, MCR, MRC, and STC.

0010 As for 0001, and adds generic CDP2, LDC2, MCR2, MRC2, and STC2.

0011 As for 0010, and adds generic MCRR and MRRC.

0100 As for 0011, and adds generic MCRR2 and MRRC2.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

CmpBranch, bits [15:12]

Indicates the implemented combined Compare and Branch instructions in the T32 instruction set. Defined values are:

0000 None implemented.

0001 Adds CBNZ and CBZ.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

BitField, bits [11:8]

Indicates the implemented BitField instructions. Defined values are:

0000 None implemented.

0001 Adds BFC, BFI, SBFX, and UBFX.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

BitCount, bits [7:4]

Indicates the implemented Bit Counting instructions. Defined values are:

0000 None implemented.

0001 Adds CLZ.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Swap, bits [3:0]

Indicates the implemented Swap instructions in the A32 instruction set. Defined values are:

0000 None implemented.

0001 Adds SWP and SWPB.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

Accessing the ID_ISAR0_EL1:

To access the ID_ISAR0_EL1:

MRS <Xt>, ID_ISAR0_EL1 ; Read ID_ISAR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 000 |

D7.2.49 ID_ISAR1_EL1, AArch32 Instruction Set Attribute Register 1

The ID_ISAR1_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR0_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR1_EL1 is architecturally mapped to AArch32 System register [ID_ISAR1](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR1_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR1_EL1 bit assignments are:

| | | | | | | | | | | | | | | | | | |
|---------|----|----|----|-----------|----|----|-----------|----|--------|----|--------|---|-----------|---|--------|--|--------|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 | | |
| Jazelle | | | | Interwork | | | Immediate | | IfThen | | Extend | | Except_AR | | Except | | Endian |

Jazelle, bits [31:28]

Indicates the implemented Jazelle extension instructions. Defined values are:

0000 No support for Jazelle.

0001 Adds the BXJ instruction, and the J bit in the PSR. This setting might indicate a trivial implementation of the Jazelle extension.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Interwork, bits [27:24]

Indicates the implemented Interworking instructions. Defined values are:

0000 None implemented.

0001 Adds the BX instruction, and the T bit in the PSR.

- 0010 As for 0001, and adds the BLX instruction. PC loads have BX-like behavior.
- 0011 As for 0010, and guarantees that data-processing instructions in the A32 instruction set with the PC as the destination and the S bit clear have BX-like behavior.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

Immediate, bits [23:20]

Indicates the implemented data-processing instructions with long immediates. Defined values are:

- 0000 None implemented.
- 0001 Adds:
- The MOVT instruction.
 - The MOV instruction encodings with zero-extended 16-bit immediates.
 - The T32 ADD and SUB instruction encodings with zero-extended 12-bit immediates, and the other ADD, ADR, and SUB encodings cross-referenced by the pseudocode for those encodings.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

IfThen, bits [19:16]

Indicates the implemented If-Then instructions in the T32 instruction set. Defined values are:

- 0000 None implemented.
- 0001 Adds the IT instructions, and the IT bits in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Extend, bits [15:12]

Indicates the implemented Extend instructions. Defined values are:

- 0000 No scalar sign-extend or zero-extend instructions are implemented, where scalar instructions means non-Advanced SIMD instructions.
- 0001 Adds the SXTB, SXTH, UXTB, and UXTH instructions.
- 0010 As for 0001, and adds the SXTB16, SXTAB, SXTAB16, SXTAH, UXTB16, UXTAB, UXTAB16, and UXTAH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Except_AR, bits [11:8]

Indicates the implemented A and R profile exception-handling instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the SRS and RFE instructions, and the A and R profile forms of the CPS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Except, bits [7:4]

Indicates the implemented exception-handling instructions in the ARM instruction set. Defined values are:

- 0000 Not implemented. This indicates that the User bank and Exception return forms of the LDM and STM instructions are not implemented.
- 0001 Adds the LDM (exception return), LDM (user registers), and STM (user registers) instruction versions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Endian, bits [3:0]

Indicates the implemented Endian instructions. Defined values are:

0000 None implemented.

0001 Adds the SETEND instruction, and the E bit in the PSRs.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

Accessing the ID_ISAR1_EL1:

To access the ID_ISAR1_EL1:

MRS <Xt>, ID_ISAR1_EL1 ; Read ID_ISAR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 001 |

D7.2.50 ID_ISAR2_EL1, AArch32 Instruction Set Attribute Register 2

The ID_ISAR2_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR3_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR2_EL1 is architecturally mapped to AArch32 System register [ID_ISAR2](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR2_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR2_EL1 bit assignments are:

Reversal, bits [31:28]

Indicates the implemented Reversal instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the REV, REV16, and REVSH instructions.
- 0010 As for 0001, and adds the RBIT instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

PSR_AR, bits [27:24]

Indicates the implemented A and R profile instructions to manipulate the PSR. Defined values are:

0000 None implemented.

0001 Adds the MRS and MSR instructions, and the exception return forms of data-processing instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

The exception return forms of the data-processing instructions are:

- In the A32 instruction set, data-processing instructions with the PC as the destination and the S bit set. These instructions might be affected by the WithShifts attribute.
- In the T32 instruction set, the SUBS PC,LR,#N instruction.

MultU, bits [23:20]

Indicates the implemented advanced unsigned Multiply instructions. Defined values are:

0000 None implemented.

0001 Adds the UMULL and UMLAL instructions.

0010 As for 0001, and adds the UMAAL instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

MultS, bits [19:16]

Indicates the implemented advanced signed Multiply instructions. Defined values are:

0000 None implemented.

0001 Adds the SMULL and SMLAL instructions.

0010 As for 0001, and adds the SMLABB, SMLABT, SMLALBB, SMLALBT, SMLALTB, SMLALTT, SMLATB, SMLATT, SMLAWB, SMLAWT, SMULBB, SMULBT, SMULTB, SMULTT, SMULWB, and SMULWT instructions. Also adds the Q bit in the PSRs.

0011 As for 0010, and adds the SMLAD, SMLADX, SMLALD, SMLALDX, SMLSD, SMLSDX, SMLSLD, SMLSLDX, SMMLA, SMMLAR, SMMLS, SMMLSR, SMMUL, SMMULR, SMUAD, SMUADX, SMUSD, and SMUSDX instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

Mult, bits [15:12]

Indicates the implemented additional Multiply instructions. Defined values are:

0000 No additional instructions implemented. This means only MUL is implemented.

0001 Adds the MLA instruction.

0010 As for 0001, and adds the MLS instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

MultiAccessInt, bits [11:8]

Indicates the support for interruptible multi-access instructions. Defined values are:

0000 No support. This means the LDM and STM instructions are not interruptible.

0001 LDM and STM instructions are restartable.

0010 LDM and STM instructions are continuable.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

MemHint, bits [7:4]

Indicates the implemented Memory Hint instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the PLD instruction.
- 0010 Adds the PLD instruction. (0001 and 0010 have identical effects.)
- 0011 As for 0001 (or 0010), and adds the PLI instruction.
- 0100 As for 0011, and adds the PLDW instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.

LoadStore, bits [3:0]

Indicates the implemented additional load/store instructions. Defined values are:

- 0000 No additional load/store instructions implemented.
- 0001 Adds the LDRD and STRD instructions.
- 0010 As for 0001, and adds the Load Acquire (LDAB, LDAH, LDA, LDAEXB, LDAEXH, LDAEX, LDAEXD) and Store Release (STLB, STLH, STL, STLEXB, STLEXH, STLEX, STLEXD) instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR2_EL1:

To access the ID_ISAR2_EL1:

MRS <Xt>, ID_ISAR2_EL1 ; Read ID_ISAR2_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 010 |

D7.2.51 ID_ISAR3_EL1, AArch32 Instruction Set Attribute Register 3

The ID_ISAR3_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR4_EL1](#), and [ID_ISAR5_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR3_EL1 is architecturally mapped to AArch32 System register [ID_ISAR3](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR3_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR3_EL1 bit assignments are:

| | | | | | | | | |
|-------|---------|---------|-----------|-----------|-------|------|----------|---|
| 31 | 28 27 | 24 23 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| T32EE | TrueNOP | T32Copy | TabBranch | SynchPrim | SVC | SIMD | Saturate | |

T32EE, bits [31:28]

Indicates the implemented T32EE instructions. Defined values are:

0000 None implemented.

0001 Adds the ENTERX and LEAVEX instructions, and modifies the load behavior to include null checking.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

TrueNOP, bits [27:24]

Indicates the implemented true NOP instructions. Defined values are:

0000 None implemented. This means there are no NOP instructions that do not have any register dependencies.

0001 Adds true NOP instructions in both the T32 and A32 instruction sets. This also permits additional NOP-compatible hints.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

T32Copy, bits [23:20]

Indicates the support for T32 non flag-setting MOV instructions. Defined values are:

0000 Not supported. This means that in the T32 instruction set, encoding T1 of the MOV (register) instruction does not support a copy from a low register to a low register.

0001 Adds support for T32 instruction set encoding T1 of the MOV (register) instruction, copying from a low register to a low register.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

TabBranch, bits [19:16]

Indicates the implemented Table Branch instructions in the T32 instruction set. Defined values are:

0000 None implemented.

0001 Adds the TBB and TBH instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SynchPrim, bits [15:12]

Used in conjunction with ID_ISAR4.SynchPrim_frac to indicate the implemented Synchronization Primitive instructions. Defined values are:

0000 If SynchPrim_frac == 0000, no Synchronization Primitives implemented.

0001 If SynchPrim_frac == 0000, adds the LDREX and STREX instructions.

If SynchPrim_frac == 0011, also adds the CLREX, LDREXB, STREXB, and STREXH instructions.

0010 If SynchPrim_frac == 0000, as for [0001, 0011] and also adds the LDREXD and STREXD instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0010.

SVC, bits [11:8]

Indicates the implemented SVC instructions. Defined values are:

0000 Not implemented.

0001 Adds the SVC instruction.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SIMD, bits [7:4]

Indicates the implemented SIMD instructions. Defined values are:

0000 None implemented.

0001 Adds the SSAT and USAT instructions, and the Q bit in the PSRs.

0011 As for 0001, and adds the PKHBT, PKHTB, QADD16, QADD8, QASX, QSUB16, QSUB8, QSAX, SADD16, SADD8, SASX, SEL, SHADD16, SHADD8, SHASX, SHSUB16, SHSUB8, SHSAX, SSAT16, SSUB16, SSUB8, SSAX, SXTAB16, SXTB16, UADD16, UADD8, UASX, UHADD16, UHADD8, UHASX, UHSUB16, UHSUB8, UHSAX, UQADD16, UQADD8, UQASX, UQSUB16, UQSUB8, UQSAX, USAD8, USADA8, USAT16, USUB16, USUB8, USAX, UXTAB16, and UXTB16 instructions. Also adds support for the GE[3:0] bits in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

The SIMD field relates only to implemented instructions that perform SIMD operations on the general-purpose registers. In an implementation that supports floating-point and Advanced SIMD instructions, [MVFR0](#), [MVFR1](#), and [MVFR2](#) give information about the implemented Advanced SIMD instructions.

Saturate, bits [3:0]

Indicates the implemented Saturate instructions. Defined values are:

0000 None implemented. This means no non-Advanced SIMD saturate instructions are implemented.

0001 Adds the QADD, QDADD, QDSUB, and QSUB instructions, and the Q bit in the PSRs.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_ISAR3_EL1:

To access the ID_ISAR3_EL1:

MRS <Xt>, ID_ISAR3_EL1 ; Read ID_ISAR3_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 011 |

D7.2.52 ID_ISAR4_EL1, AArch32 Instruction Set Attribute Register 4

The ID_ISAR4_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), and [ID_ISAR5_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR4_EL1 is architecturally mapped to AArch32 System register [ID_ISAR4](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR4_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR4_EL1 bit assignments are:

SWP_frac, bits [31:28]

Indicates support for the memory system locking the bus for SWP or SWPB instructions. Defined values are:

- 0000 SWP or SWPB instructions not implemented.
- 0001 SWP or SWPB implemented but only in a uniprocessor context. SWP and SWPB do not guarantee whether memory accesses from other masters can come between the load memory access and the store memory access of the SWP or SWPB.

All other values are reserved. This field is valid only if the [ID_ISAR0.Swap_insts](#) field is 0000.

In ARMv8-A the only permitted value is 0000.

PSR_M, bits [27:24]

Indicates the implemented M profile instructions to modify the PSRs. Defined values are:

- 0000 None implemented.
 - 0001 Adds the M profile forms of the CPS, MRS, and MSR instructions.
- All other values are reserved.

In ARMv8-A the only permitted value is 0000.

SynchPrim_frac, bits [23:20]

Used in conjunction with ID_ISAR3.SynchPrim to indicate the implemented Synchronization Primitive instructions. Possible values are:

- 0000 If SynchPrim == 0000, no Synchronization Primitives implemented. If SynchPrim == 0001, adds the LDREX and STREX instructions. If SynchPrim == 0010, also adds the CLREX, LDREXB, LDREXH, STREXB, STREXH, LDREXD, and STREXD instructions.
- 0011 If SynchPrim == 0001, adds the LDREX, STREX, CLREX, LDREXB, LDREXH, STREXB, and STREXH instructions.

All other combinations of SynchPrim and SynchPrim_frac are reserved.

In ARMv8-A the only permitted value is 0000.

Barrier, bits [19:16]

Indicates the implemented Barrier instructions in the A32 and T32 instruction sets. Defined values are:

- 0000 None implemented. Barrier operations are provided only as System instructions in the (coproc==1111) encoding space.
- 0001 Adds the DMB, DSB, and ISB barrier instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

SMC, bits [15:12]

Indicates the implemented SMC instructions. Defined values are:

- 0000 None implemented.
- 0001 Adds the SMC instruction.

All other values are reserved.

In ARMv8-A the permitted values are 0001 and 0000.

If EL1 cannot use AArch32 then this field has the value 0000.

Writeback, bits [11:8]

Indicates the support for Writeback addressing modes. Defined values are:

- 0000 Basic support. Only the LDM, STM, PUSH, POP, SRS, and RFE instructions support writeback addressing modes. These instructions support all of their writeback addressing modes.
- 0001 Adds support for all of the writeback addressing modes.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

WithShifts, bits [7:4]

Indicates the support for instructions with shifts. Defined values are:

- 0000 Nonzero shifts supported only in MOV and shift instructions.
- 0001 Adds support for shifts of loads and stores over the range LSL 0-3.

0011 As for 0001, and adds support for other constant shift options, both on load/store and other instructions.

0100 As for 0011, and adds support for register-controlled shift options.

All other values are reserved.

In ARMv8-A the only permitted value is 0100.

Unpriv, bits [3:0]

Indicates the implemented unprivileged instructions. Defined values are:

0000 None implemented. No T variant instructions are implemented.

0001 Adds the LDRBT, LDRT, STRBT, and STRT instructions.

0010 As for 0001, and adds the LDRHT, LDRSBT, LDRSHT, and STRHT instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

Accessing the ID_ISAR4_EL1:

To access the ID_ISAR4_EL1:

MRS <Xt>, ID_ISAR4_EL1 ; Read ID_ISAR4_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 100 |

D7.2.53 ID_ISAR5_EL1, AArch32 Instruction Set Attribute Register 5

The ID_ISAR5_EL1 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR0_EL1](#), [ID_ISAR1_EL1](#), [ID_ISAR2_EL1](#), [ID_ISAR3_EL1](#), and [ID_ISAR4_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_ISAR5_EL1 is architecturally mapped to AArch32 System register [ID_ISAR5](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_ISAR5_EL1 is a 32-bit register.

Field descriptions

The ID_ISAR5_EL1 bit assignments are:

| | | | | | | |
|------|-------|-------|-------|-----|------|---|
| 31 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| RES0 | CRC32 | SHA2 | SHA1 | AES | SEVL | |

Bits [31:20]

Reserved, RES0.

CRC32, bits [19:16]

Indicates whether CRC32 instructions are implemented in AArch32.

0000 No CRC32 instructions implemented.

0001 CRC32B, CRC32H, CRC32W, CRC32CB, CRC32CH, and CRC32CW instructions implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SHA2, bits [15:12]

Indicates whether SHA2 instructions are implemented in AArch32.

0000 No SHA2 instructions implemented.

0001 SHA256H, SHA256H2, SHA256SU0, and SHA256SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SHA1, bits [11:8]

Indicates whether SHA1 instructions are implemented in AArch32.

0000 No SHA1 instructions implemented.

0001 SHA1C, SHA1P, SHA1M, SHA1H, SHA1SU0, and SHA1SU1 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

AES, bits [7:4]

Indicates whether AES instructions are implemented in AArch32.

0000 No AES instructions implemented.

0001 AESE, AESD, AESMC, and AESIMC implemented.

0010 As for 0001, plus PMULL/PMULL2 instructions operating on 64-bit data quantities.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

SEVL, bits [3:0]

Indicates whether the SEVL instruction is implemented in AArch32.

0000 SEVL is implemented as a NOP.

0001 SEVL is implemented as Send Event Local.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_ISAR5_EL1:

To access the ID_ISAR5_EL1:

MRS <Xt>, ID_ISAR5_EL1 ; Read ID_ISAR5_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 101 |

D7.2.54 ID_MMFR0_EL1, AArch32 Memory Model Feature Register 0

The ID_MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Must be interpreted with [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), and [ID_MMFR4_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_MMFR0_EL1 is architecturally mapped to AArch32 System register [ID_MMFR0](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR0_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR0_EL1 bit assignments are:

| | | | | | | | | | | | | | | | | |
|----------|----|----|----|------|----|--------|----|-----|----|----------|---|----------|---|------|---|------|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 | |
| InnerShr | | | | FCSE | | AuxReg | | TCM | | ShareLvl | | OuterShr | | PMSA | | VMSA |

InnerShr, bits [31:28]

Innermost Shareability. Indicates the innermost shareability domain implemented. Defined values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

This field is valid only if the implementation supports two levels of shareability, as indicated by [ID_MMFR0_EL1.ShareLvl](#) having the value 0001.

When ID_MMFR0_EL1.ShareLvl is zero, this field is UNK.

FCSE, bits [27:24]

Indicates whether the implementation includes the FCSE. Defined values are:

- 0000 Not supported.
- 0001 Support for FCSE.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

AuxReg, bits [23:20]

Auxiliary Registers. Indicates support for Auxiliary registers. Defined values are:

- 0000 None supported.
- 0001 Support for Auxiliary Control Register only.
- 0010 Support for Auxiliary Fault Status Registers (AIFSR and ADFSR) and Auxiliary Control Register.

All other values are reserved.

In ARMv8 the only permitted value is 0010.

———— **Note** —————

Accesses to unimplemented Auxiliary registers are UNDEFINED.

TCM, bits [19:16]

Indicates support for TCMs and associated DMAs. Defined values are:

- 0000 Not supported.
- 0001 Support is IMPLEMENTATION DEFINED. ARMv7 requires this setting.
- 0010 Support for TCM only, ARMv6 implementation.
- 0011 Support for TCM and DMA, ARMv6 implementation.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

ShareLvl, bits [15:12]

Shareability Levels. Indicates the number of shareability levels implemented. Defined values are:

- 0000 One level of shareability implemented.
- 0001 Two levels of shareability implemented.

All other values are reserved.

In ARMv8 the only permitted value is 0001.

OuterShr, bits [11:8]

Outermost Shareability. Indicates the outermost shareability domain implemented. Defined values are:

- 0000 Implemented as Non-cacheable.
- 0001 Implemented with hardware coherency support.
- 1111 Shareability ignored.

All other values are reserved.

In ARMv8 the permitted values are 0000, 0001, and 1111.

PMSA, bits [7:4]

Indicates support for a PMSA. Defined values are:

- 0000 Not supported.

- 0001 Support for IMPLEMENTATION DEFINED PMSA.
- 0010 Support for PMSAv6, with a Cache Type Register implemented.
- 0011 Support for PMSAv7, with support for memory subsections. ARMv7-R profile.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

VMSA, bits [3:0]

Indicates support for a VMSA. Defined values are:

- 0000 Not supported.
- 0001 Support for IMPLEMENTATION DEFINED VMSA.
- 0010 Support for VMSAv6, with Cache and TLB Type Registers implemented.
- 0011 Support for VMSAv7, with support for remapping and the Access flag. ARMv7-A profile.
- 0100 As for 0011, and adds support for the PXN bit in the Short-descriptor translation table format descriptors.
- 0101 As for 0100, and adds support for the Long-descriptor translation table format.

All other values are reserved.

In ARMv8-A the only permitted value is 0101.

Accessing the ID_MMFR0_EL1:

To access the ID_MMFR0_EL1:

MRS <Xt>, ID_MMFR0_EL1 ; Read ID_MMFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 100 |

D7.2.55 ID_MMFR1_EL1, AArch32 Memory Model Feature Register 1

The ID_MMFR1_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Must be interpreted with [ID_MMFR0_EL1](#), [ID_MMFR2_EL1](#), [ID_MMFR3_EL1](#), and [ID_MMFR4_EL1](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_MMFR1_EL1 is architecturally mapped to AArch32 System register [ID_MMFR1](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR1_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR1_EL1 bit assignments are:

| | | | | | | | | | | | | | | | |
|-------|----------|-------|-------|---------|---------|---------|---------|----|----|----|---|---|---|---|---|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 |
| BPred | L1TstCln | L1Uni | L1Hvd | L1UniSW | L1HvdSW | L1UniVA | L1HvdVA | | | | | | | | |

BPred, bits [31:28]

Branch Predictor. Indicates branch predictor management requirements. Defined values are:

0000 No branch predictor, or no MMU present. Implies a fixed MPU configuration.

0001 Branch predictor requires flushing on:

- Enabling or disabling a stage of address translation.
- Writing new data to instruction locations.
- Writing new mappings to the translation tables.
- Changes to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers.
- Changes to the ContextID or ASID, or to the FCSE ProcessID if this is supported.

- 0010 Branch predictor requires flushing on:
- Enabling or disabling a stage of address translation.
 - Writing new data to instruction locations.
 - Writing new mappings to the translation tables.
 - Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers without a change to the corresponding ContextID or ASID, or FCSE ProcessID if this is supported.
- 0011 Branch predictor requires flushing only on writing new data to instruction locations.
- 0100 For execution correctness, branch predictor requires no flushing at any time.

All other values are reserved.

In ARMv8-A the permitted values are 0010, 0011, or 0100. For values other than 0000 and 0100 the ARM Architecture Reference Manual, or the product documentation, might give more information about the required maintenance.

L1TstCln, bits [27:24]

Level 1 cache Test and Clean. Indicates the supported Level 1 data cache test and clean operations, for Harvard or unified cache implementations. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 data cache test and clean operations are:
- Test and clean data cache.
- 0010 As for 0001, and adds:
- Test, clean, and invalidate data cache.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Uni, bits [23:20]

Level 1 Unified cache. Indicates the supported entire Level 1 cache maintenance operations for a unified cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported entire Level 1 cache operations are:
- Invalidate cache, including branch predictor if appropriate.
 - Invalidate branch predictor, if appropriate.
- 0010 As for 0001, and adds:
- Clean cache, using a recursive model that uses the cache dirty status bit.
 - Clean and invalidate cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1Hvd, bits [19:16]

Level 1 Harvard cache. Indicates the supported entire Level 1 cache maintenance operations for a Harvard cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported entire Level 1 cache operations are:
- Invalidate instruction cache, including branch predictor if appropriate.
 - Invalidate branch predictor, if appropriate.
- 0010 As for 0001, and adds:
- Invalidate data cache.

- Invalidate data cache and instruction cache, including branch predictor if appropriate.
- 0011 As for 0010, and adds:
- Clean data cache, using a recursive model that uses the cache dirty status bit.
 - Clean and invalidate data cache, using a recursive model that uses the cache dirty status bit.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1UniSW, bits [15:12]

Level 1 Unified cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a unified cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 unified cache line maintenance operations by set/way are:
- Clean cache line by set/way.
- 0010 As for 0001, and adds:
- Clean and invalidate cache line by set/way.
- 0011 As for 0010, and adds:
- Invalidate cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1HvdSW, bits [11:8]

Level 1 Harvard cache by Set/Way. Indicates the supported Level 1 cache line maintenance operations by set/way, for a Harvard cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 Harvard cache line maintenance operations by set/way are:
- Clean data cache line by set/way.
 - Clean and invalidate data cache line by set/way.
- 0010 As for 0001, and adds:
- Invalidate data cache line by set/way.
- 0011 As for 0010, and adds:
- Invalidate instruction cache line by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1UniVA, bits [7:4]

Level 1 Unified cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a unified cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 unified cache line maintenance operations by VA are:
- Clean cache line by VA.
 - Invalidate cache line by VA.
 - Clean and invalidate cache line by VA.
- 0010 As for 0001, and adds:
- Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

L1HvdVA, bits [3:0]

Level 1 Harvard cache by Virtual Address. Indicates the supported Level 1 cache line maintenance operations by VA, for a Harvard cache implementation. Defined values are:

- 0000 None supported.
- 0001 Supported Level 1 Harvard cache line maintenance operations by VA are:
 - Clean data cache line by VA.
 - Invalidate data cache line by VA.
 - Clean and invalidate data cache line by VA.
 - Clean instruction cache line by VA.
- 0010 As for 0001, and adds:
 - Invalidate branch predictor by VA, if branch predictor is implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

Accessing the ID_MMFR1_EL1:

To access the ID_MMFR1_EL1:

MRS <Xt>, ID_MMFR1_EL1 ; Read ID_MMFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 101 |

D7.2.56 ID_MMFR2_EL1, AArch32 Memory Model Feature Register 2

The ID_MMFR2_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Must be interpreted with [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR3_EL1](#), and [ID_MMFR4_EL1](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_MMFR2_EL1 is architecturally mapped to AArch32 System register [ID_MMFR2](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR2_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR2_EL1 bit assignments are:

| | | | | | | | | | | | | | | | |
|----------|------------|---------|--------|--------|----------|---------|---------|----|----|----|---|---|---|---|---|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 |
| HWAccFlg | WFIS Stall | MemBarr | UniTLB | HvdTLB | L1HvdRng | L1HvdBG | L1HvdFG | | | | | | | | |

HWAccFlg, bits [31:28]

Hardware Access Flag. In earlier versions of the ARM Architecture, this field indicates support for a Hardware Access flag, as part of the VMSAv7 implementation. Defined values are:

0000 Not supported.

0001 Support for VMSAv7 Access flag, updated in hardware.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

WFIS Stall, bits [27:24]

Wait For Interrupt Stall. Indicates the support for Wait For Interrupt (WFI) stalling. Defined values are:

- 0000 Not supported.
- 0001 Support for WFI stalling.

All other values are reserved.

In ARMv8 the permitted values are 0000 and 0001.

MemBarr, bits [23:20]

Memory Barrier. Indicates the supported memory barrier System instructions in the (coproc==1111) encoding space:

- 0000 None supported.
- 0001 Supported memory barrier System instructions are:
 - Data Synchronization Barrier (DSB).
- 0010 As for 0001, and adds:
 - Instruction Synchronization Barrier (ISB).
 - Data Memory Barrier (DMB).

All other values are reserved.

In ARMv8 the only permitted value is 0010.

ARM deprecates the use of these operations. ID_ISAR4.Barrier_insts indicates the level of support for the preferred barrier instructions.

UniTLB, bits [19:16]

Unified TLB. Indicates the supported TLB maintenance operations, for a unified TLB implementation. Defined values are:

- 0000 Not supported.
- 0001 Supported unified TLB maintenance operations are:
 - Invalidate all entries in the TLB.
 - Invalidate TLB entry by VA.
- 0010 As for 0001, and adds:
 - Invalidate TLB entries by ASID match.
- 0011 As for 0010, and adds:
 - Invalidate instruction TLB and data TLB entries by VA All ASID. This is a shared unified TLB operation.
- 0100 As for 0011, and adds:
 - Invalidate Hyp mode unified TLB entry by VA.
 - Invalidate entire Non-secure PL1&0 unified TLB.
 - Invalidate entire Hyp mode unified TLB.
- 0101 As for 0100, and adds the following operations: [TLBIMVALIS](#), [TLBIMVAALIS](#), [TLBIMVALHIS](#), [TLBIMVAL](#), [TLBIMVAAL](#), [TLBIMVALH](#).
- 0110 As for 0101, and adds the following operations: [TLBIIPAS2IS](#), [TLBIIPAS2LIS](#), [TLBIIPAS2](#), [TLBIIPAS2L](#).

All other values are reserved.

In ARMv8-A the only permitted value is 0110.

HvdTLB, bits [15:12]

If the Unified TLB field (UniTLB, bits [19:16]) is not 0000, then the meaning of this field is IMPLEMENTATION DEFINED. ARM deprecates the use of this field by software.

L1HvdRng, bits [11:8]

Level 1 Harvard cache Range. Indicates the supported Level 1 cache maintenance range operations, for a Harvard cache implementation. Defined values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache maintenance range operations are:

- Invalidate data cache range by VA.
- Invalidate instruction cache range by VA.
- Clean data cache range by VA.
- Clean and invalidate data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

L1HvdBG, bits [7:4]

Level 1 Harvard cache Background fetch. Indicates the supported Level 1 cache background fetch operations, for a Harvard cache implementation. When supported, background fetch operations are non-blocking operations. Defined values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache background fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

L1HvdFG, bits [3:0]

Level 1 Harvard cache Foreground fetch. Indicates the supported Level 1 cache foreground fetch operations, for a Harvard cache implementation. When supported, foreground fetch operations are blocking operations. Defined values are:

0000 Not supported.

0001 Supported Level 1 Harvard cache foreground fetch operations are:

- Fetch instruction cache range by VA.
- Fetch data cache range by VA.

All other values are reserved.

In ARMv8 the only permitted value is 0000.

Accessing the ID_MMFR2_EL1:

To access the ID_MMFR2_EL1:

MRS <Xt>, ID_MMFR2_EL1 ; Read ID_MMFR2_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 110 |

D7.2.57 ID_MMFR3_EL1, AArch32 Memory Model Feature Register 3

The ID_MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Must be interpreted with [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), and [ID_MMFR4_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers](#) on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548. Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_MMFR3_EL1 is architecturally mapped to AArch32 System register [ID_MMFR3](#).

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR3_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR3_EL1 bit assignments are:

| | | | | | | | | |
|----------|--------|---------|-------|-----------|---------|----------|----------|---|
| 31 | 28 27 | 24 23 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| Supersec | CMemSz | CohWalk | RES0 | MaintBcst | BPMaint | CMaintSW | CMaintVA | |

Supersec, bits [31:28]

Supersections. On a VMSA implementation, indicates whether Supersections are supported. Defined values are:

0000 Supersections supported.

1111 Supersections not supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 1111.

CMemSz, bits [27:24]

Cached Memory Size. Indicates the physical memory size supported by the caches. Defined values are:

- 0000 4GB, corresponding to a 32-bit physical address range.
- 0001 64GB, corresponding to a 36-bit physical address range.
- 0010 1TB or more, corresponding to a 40-bit or larger physical address range.

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0001, and 0010.

CohWalk, bits [23:20]

Coherent Walk. Indicates whether Translation table updates require a clean to the point of unification. Defined values are:

- 0000 Updates to the translation tables require a clean to the point of unification to ensure visibility by subsequent translation table walks.
- 0001 Updates to the translation tables do not require a clean to the point of unification to ensure visibility by subsequent translation table walks.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Bits [19:16]

Reserved, RES0.

MaintBcst, bits [15:12]

Maintenance Broadcast. Indicates whether Cache, TLB, and branch predictor operations are broadcast. Defined values are:

- 0000 Cache, TLB, and branch predictor operations only affect local structures.
- 0001 Cache and branch predictor operations affect structures according to shareability and defined behavior of instructions. TLB operations only affect local structures.
- 0010 Cache, TLB, and branch predictor operations affect structures according to shareability and defined behavior of instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

BPMaint, bits [11:8]

Branch Predictor Maintenance. Indicates the supported branch predictor maintenance operations in an implementation with hierarchical cache maintenance operations. Defined values are:

- 0000 None supported.
- 0001 Supported branch predictor maintenance operations are:
 - Invalidate all branch predictors.
- 0010 As for 0001, and adds:
 - Invalidate branch predictors by VA.

All other values are reserved.

In ARMv8-A the only permitted value is 0010.

CMaintSW, bits [7:4]

Cache Maintenance by Set/Way. Indicates the supported cache maintenance operations by set/way, in an implementation with hierarchical caches. Defined values are:

- 0000 None supported.
- 0001 Supported hierarchical cache maintenance instructions by set/way are:
 - Invalidate data cache by set/way.

- Clean data cache by set/way.
- Clean and invalidate data cache by set/way.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

In a unified cache implementation, the data cache maintenance operations apply to the unified caches.

CMaintVA, bits [3:0]

Cache Maintenance by Virtual Address. Indicates the supported cache maintenance operations by VA, in an implementation with hierarchical caches. Defined values are:

0000 None supported.

0001 Supported hierarchical cache maintenance operations by VA are:

- Invalidate data cache by VA.
- Clean data cache by VA.
- Clean and invalidate data cache by VA.
- Invalidate instruction cache by VA.
- Invalidate all instruction cache entries.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

In a unified cache implementation, data cache maintenance operations apply to the unified caches, and the instruction cache maintenance instructions are not implemented.

Accessing the ID_MMFR3_EL1:

To access the ID_MMFR3_EL1:

MRS <Xt>, ID_MMFR3_EL1 ; Read ID_MMFR3_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 111 |

D7.2.58 ID_MMFR4_EL1, AArch32 Memory Model Feature Register 4

The ID_MMFR4_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch32.

Must be interpreted with [ID_MMFR0_EL1](#), [ID_MMFR1_EL1](#), [ID_MMFR2_EL1](#), and [ID_MMFR3_EL1](#).

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

If [HCR_EL2.TID3](#)==1, then:

- If the register is not RAZ/WI then Non-secure EL1 read accesses to this register are trapped to EL2.
- Otherwise, it is IMPLEMENTATION DEFINED whether Non-secure EL1 read accesses to this register are trapped to EL2.

Configurations

AArch64 System register ID_MMFR4_EL1 is architecturally mapped to AArch32 System register [ID_MMFR4](#).

In an implementation that does not include [ACTLR2](#) and [HACTLR2](#) this register is RAZ.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_MMFR4_EL1 is a 32-bit register.

Field descriptions

The ID_MMFR4_EL1 bit assignments are:

Bits [31:8]

Reserved, RAZ.

AC2, bits [7:4]

Indicates the extension of the [ACTLR](#) and [HACTLR](#) registers using [ACTLR2](#) and [HACTLR2](#).

Defined values are:

0000 [ACTLR2](#) and [HACTLR2](#) are not implemented.

0001 [ACTLR2](#) and [HACTLR2](#) are implemented.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0001.

Bits [3:0]

Reserved, RAZ.

Accessing the ID_MMFR4_EL1:

To access the ID_MMFR4_EL1:

MRS <Xt>, ID_MMFR4_EL1 ; Read ID_MMFR4_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0010 | 110 |

D7.2.59 ID_PFR0_EL1, AArch32 Processor Feature Register 0

The ID_PFR0_EL1 characteristics are:

Purpose

Gives top-level information about the instruction sets supported by the PE in AArch32.

Must be interpreted with ID_PFR1_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_PFR0_EL1 is architecturally mapped to AArch32 System register ID_PFR0.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_PFR0_EL1 is a 32-bit register.

Field descriptions

The ID_PFR0_EL1 bit assignments are:

Bits [31:16]

Reserved, RES0.

State3, bits [15:12]

T32EE instruction set support. Defined values are:

0000 Not implemented.

0001 T32EE instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

State2, bits [11:8]

Jazelle extension support. Defined values are:

0000 Not implemented.

0001 Jazelle extension implemented, without clearing of **JOSCR.CV** on exception entry.

0010 Jazelle extension implemented, with clearing of **JOSCR.CV** on exception entry.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

State1, bits [7:4]

T32 instruction set support. Defined values are:

0000 T32 instruction set not implemented.

0001 T32 encodings before the introduction of Thumb-2 technology implemented:

- All instructions are 16-bit.
- A BL or BLX is a pair of 16-bit instructions.
- 32-bit instructions other than BL and BLX cannot be encoded.

0011 T32 encodings after the introduction of Thumb-2 technology implemented, for all 16-bit and 32-bit T32 basic instructions.

All other values are reserved.

In ARMv8-A the only permitted value is 0011.

State0, bits [3:0]

A32 instruction set support. Defined values are:

0000 A32 instruction set not implemented.

0001 A32 instruction set implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Accessing the ID_PFR0_EL1:

To access the ID_PFR0_EL1:

MRS <Xt>, ID_PFR0_EL1 ; Read ID_PFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 000 |

D7.2.60 ID_PFR1_EL1, AArch32 Processor Feature Register 1

The ID_PFR1_EL1 characteristics are:

Purpose

Gives information about the AArch32 programmers' model.

Must be interpreted with ID_PFR0_EL1.

For general information about the interpretation of the ID registers see *Principles of the ID scheme for fields in ID registers* on page D7-1893.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If HCR_EL2.TID3==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register ID_PFR1_EL1 is architecturally mapped to AArch32 System register ID_PFR1.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

ID_PFR1_EL1 is a 32-bit register.

Field descriptions

The ID_PFR1_EL1 bit assignments are:

GIC, bits [31:28]

System register GIC CPU interface. Defined values are:

0000 No System register interface to the GIC CPU interface is supported.

0001 System register interface to versions 3.0 and 4.0 of the GIC CPU interface is supported.

All other values are reserved.

Virt_frac, bits [27:24]

Virtualization fractional field. When the Virtualization field is 0000, determines the support for features from the ARMv7 Virtualization Extensions. Defined values are:

0000 No features from the ARMv7 Virtualization Extensions are implemented.

0001 The following features of the ARMv7 Virtualization Extensions are implemented:

- The **SCR.SIF** bit, if EL3 is implemented.
- The modifications to the **SCR.AW** and **SCR.FW** bits described in the Virtualization Extensions, if EL3 is implemented.
- The MSR (Banked register) and MRS (Banked register) instructions.
- The ERET instruction.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

This field is only valid when the value of ID_PFR1_EL1.Virtualization is 0, otherwise it holds the value 0000.

———— **Note** —————

The ID_ISAR registers do not identify whether the instructions added by the ARMv7 Virtualization Extensions are implemented.

Sec_frac, bits [23:20]

Security fractional field. When the Security field is 0000, determines the support for features from the ARMv7 Security Extensions. Defined values are:

0000 No features from the ARMv7 Security Extensions are implemented.

0001 The following features from the ARMv7 Security Extensions are implemented:

- The VBAR register.
- The **TTBCR.PD0** and **TTBCR.PD1** bits.

0010 As for 0001, plus the ability to access Secure or Non-secure physical memory is supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0001, and 0010.

This field is only valid when the value of ID_PFR1_EL1.Security is 0, otherwise it holds the value 0000.

GenTimer, bits [19:16]

Generic Timer support. Defined values are:

0000 Not implemented.

0001 Generic Timer implemented.

All other values are reserved.

In ARMv8-A the only permitted value is 0001.

Virtualization, bits [15:12]

Virtualization support. Defined values are:

0000 EL2, Hyp mode, and the HVC instruction not implemented.

0001 EL2, Hyp mode, the HVC instruction, and all the features described by Virt_frac == 0001 implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In an implementation that includes EL2, if EL2 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

If EL1 cannot use AArch32 then this field has the value 0000.

———— **Note** ————

The ID_ISARs do not identify whether the HVC instruction is implemented.

MProgMod, bits [11:8]

M profile programmers' model support. Defined values are:

0000 Not supported.

0010 Support for two-stack programmers' model.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

Security, bits [7:4]

Security support. Defined values are:

0000 EL3, Monitor mode, and the SMC instruction not implemented.

0001 EL3, Monitor mode, the SMC instruction, and all the features described by Sec_frac == 0001 implemented.

0010 As for 0001, and adds the ability to set the NSACR.RFR bit. Not permitted in ARMv8 as the NSACR.RFR bit is RES0.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In an implementation that includes EL3, if EL3 cannot use AArch32 but EL1 can use AArch32 then this field has the value 0001.

If EL1 cannot use AArch32 then this field has the value 0000.

ProgMod, bits [3:0]

Support for the standard programmers' model for ARMv4 and later. Model must support User, FIQ, IRQ, Supervisor, Abort, Undefined, and System modes. Defined values are:

0000 Not supported.

0001 Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0001 and 0000.

If EL1 cannot use AArch32 then this field has the value 0000.

Accessing the ID_PFR1_EL1:

To access the ID_PFR1_EL1:

MRS <Xt>, ID_PFR1_EL1 ; Read ID_PFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0001 | 001 |

D7.2.61 IFSR32_EL2, Instruction Fault Status Register (EL2)

The IFSR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 [IFSR](#) register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register IFSR32_EL2 is architecturally mapped to AArch32 System register [IFSR](#).

If EL1 is AArch64 only, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

RW fields in this register reset to architecturally UNKNOWN values.

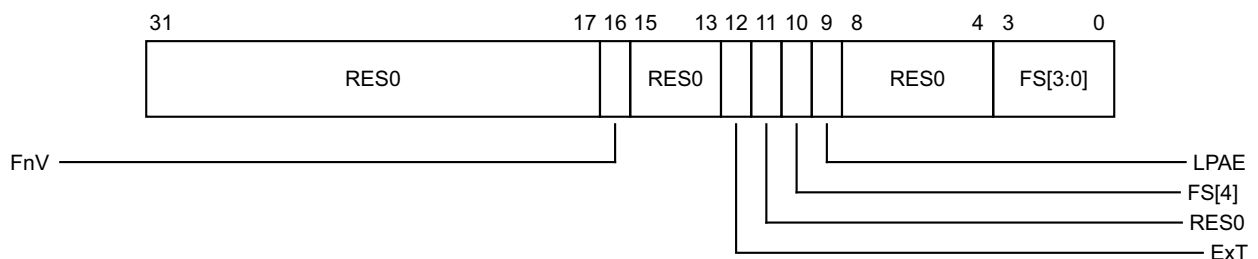

Attributes

IFSR32_EL2 is a 32-bit register.

Field descriptions

The IFSR32_EL2 bit assignments are:

When *TTBCR.EAE*=0:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 [IFAR](#) is valid.

1 [IFAR](#) is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bits [15:13]

Reserved, RES0.

Ext, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Bit [11]

Reserved, RES0.

FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:4]

Reserved, RES0.

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

00001 PC alignment fault

00010 Debug exception

00011 Access flag fault, level 1

00101 Translation fault, level 1

00110 Access flag fault, level 2

00111 Translation fault, level 2

01000 Synchronous external abort, not on translation table walk

01001 Domain fault, level 1

01011 Domain fault, level 2

01100 Synchronous external abort, on translation table walk, level 1

01101 Permission fault, level 1

01110 Synchronous external abort, on translation table walk, level 2

01111 Permission fault, level 2

10000 TLB conflict abort

10100 IMPLEMENTATION DEFINED fault (Lockdown fault)

11001 Synchronous parity or ECC error on memory access, not on translation table walk

11100 Synchronous parity or ECC error on translation table walk, level 1

11110 Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

When TTBCR.EAE==1:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 **IFAR** is valid.

1 **IFAR** is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Prefetch Abort exceptions.

Bits [15:13]

Reserved, RES0.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

Bits [11:10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

0 Using the Short-descriptor translation table formats.

1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. All encodings not shown below are reserved:

- 000000 Address size fault in **TTBR0** or **TTBR1**
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2

| | |
|--------|---|
| 000111 | Translation fault, level 3 |
| 001001 | Access flag fault, level 1 |
| 001010 | Access flag fault, level 2 |
| 001011 | Access flag fault, level 3 |
| 001101 | Permission fault, level 1 |
| 001110 | Permission fault, level 2 |
| 001111 | Permission fault, level 3 |
| 010000 | Synchronous external abort, not on translation table walk |
| 010101 | Synchronous external abort, on translation table walk, level 1 |
| 010110 | Synchronous external abort, on translation table walk, level 2 |
| 010111 | Synchronous external abort, on translation table walk, level 3 |
| 011000 | Synchronous parity or ECC error on memory access, not on translation table walk |
| 011101 | Synchronous parity or ECC error on memory access on translation table walk, level 1 |
| 011110 | Synchronous parity or ECC error on memory access on translation table walk, level 2 |
| 011111 | Synchronous parity or ECC error on memory access on translation table walk, level 3 |
| 100001 | PC alignment fault |
| 100010 | Debug exception |
| 110000 | TLB conflict abort |

All other values are reserved.

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a fault at level 1.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Accessing the IFSR32_EL2:

To access the IFSR32_EL2:

MRS <Xt>, IFSR32_EL2 ; Read IFSR32_EL2 into Xt
MSR IFSR32_EL2, <Xt> ; Write Xt to IFSR32_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0101 | 0000 | 001 |

D7.2.62 ISR_EL1, Interrupt Status Register

The ISR_EL1 characteristics are:

Purpose

Shows whether any IRQ, FIQ, or SError interrupt is pending. In an implementation that includes EL2, when the register is accessed from Non-secure EL1, a pending interrupt or external abort might be physical or virtual, and the architecture does not provide any mechanism that software executing at Non-secure EL1 can use to determine whether a pending interrupt or external abort is physical or virtual. For all other accesses, any indicated interrupt or external abort must be physical.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register ISR_EL1 is architecturally mapped to AArch32 System register [ISR](#).

Attributes

ISR_EL1 is a 32-bit register.

Field descriptions

The ISR_EL1 bit assignments are:

Bits [31:9]

Reserved, RES0.

A, bit [8]

SError interrupt pending bit:

- 0 No pending SError.
- 1 An SError interrupt is pending.

I, bit [7]

IRQ pending bit. Indicates whether an IRQ interrupt is pending:

- 0 No pending IRQ.
- 1 An IRQ interrupt is pending.

F, bit [6]

FIQ pending bit. Indicates whether an FIQ interrupt is pending.

- 0 No pending FIQ.
- 1 An FIQ interrupt is pending.

Bits [5:0]

Reserved, RES0.

Accessing the ISR_EL1:

To access the ISR_EL1:

MRS <Xt>, ISR_EL1 ; Read ISR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1100 | 0001 | 000 |

D7.2.63 MAIR_EL1, Memory Attribute Indirection Register (EL1)

The MAIR_EL1 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations at EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register `PRRR` when `TTBCR.EAE==0`.

AArch64 System register MAIR_EL1[31:0] is architecturally mapped to AArch32 System register `MAIRO` when `TTBCR.EAE==1`.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register `NMRR` when `TTBCR.EAE==0`.

AArch64 System register MAIR_EL1[63:32] is architecturally mapped to AArch32 System register `MAIR1` when `TTBCR.EAE==1`.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR_EL1 is a 64-bit register.

Field descriptions

The MAIR_EL1 bit assignments are:

MAIR_EL1 is permitted to be cached in a TLB.

Attr<n>, bits [8n+7:8n], for n = 0 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where AttrIdx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 0000 | Device memory. See encoding of Attr<n>[3:0] for the type of Device memory. |
| 00RW, RW not 00 | Normal Memory, Outer Write-Through transient |
| 0100 | Normal Memory, Outer Non-cacheable |
| 01RW, RW not 00 | Normal Memory, Outer Write-Back transient |
| 10RW | Normal Memory, Outer Write-Through non-transient |
| 11RW | Normal Memory, Outer Write-Back non-transient |

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

| Attr<n>[3:0] | Meaning when Attr<n>[7:4] is 0000 | Meaning when Attr<n>[7:4] is not 0000 |
|-----------------|-----------------------------------|--|
| 0000 | Device-nGnRnE memory | UNPREDICTABLE |
| 00RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through transient |
| 0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
| 01RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back transient |
| 1000 | Device-nGRE memory | Normal Memory, Inner Write-Through non-transient (RW=00) |
| 10RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through non-transient |
| 1100 | Device-GRE memory | Normal Memory, Inner Write-Back non-transient (RW=00) |
| 11RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
|--------|-------------|
| 0 | No Allocate |
| 1 | Allocate |

Accessing the MAIR_EL1:

To access the MAIR_EL1:

MRS <Xt>, MAIR_EL1 ; Read MAIR_EL1 into Xt
MSR MAIR_EL1, <Xt> ; Write Xt to MAIR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1010 | 0010 | 000 |

D7.2.64 MAIR_EL2, Memory Attribute Indirection Register (EL2)

The MAIR_EL2 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations at EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register MAIR_EL2[31:0] is architecturally mapped to AArch32 System register [HMAIRO](#).

AArch64 System register MAIR_EL2[63:32] is architecturally mapped to AArch32 System register [HMAIR1](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR_EL2 is a 64-bit register.

Field descriptions

The MAIR_EL2 bit assignments are:

MAIR_EL2 is permitted to be cached in a TLB.

Attr<n>, bits [8n+7:8n], for n = 0 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where AttrIdx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 0000 | Device memory. See encoding of Attr<n>[3:0] for the type of Device memory. |
| 00RW, RW not 00 | Normal Memory, Outer Write-Through transient |
| 0100 | Normal Memory, Outer Non-cacheable |

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 01RW, RW not 00 | Normal Memory, Outer Write-Back transient |
| 10RW | Normal Memory, Outer Write-Through non-transient |
| 11RW | Normal Memory, Outer Write-Back non-transient |

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

| Attr<n>[3:0] | Meaning when Attr<n>[7:4] is 0000 | Meaning when Attr<n>[7:4] is not 0000 |
|-----------------|-----------------------------------|--|
| 0000 | Device-nGnRnE memory | UNPREDICTABLE |
| 00RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through transient |
| 0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
| 01RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back transient |
| 1000 | Device-nGRE memory | Normal Memory, Inner Write-Through non-transient (RW=00) |
| 10RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through non-transient |
| 1100 | Device-GRE memory | Normal Memory, Inner Write-Back non-transient (RW=00) |
| 11RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
|--------|-------------|
| 0 | No Allocate |
| 1 | Allocate |

Accessing the MAIR_EL2:

To access the MAIR_EL2:

MRS <Xt>, MAIR_EL2 ; Read MAIR_EL2 into Xt
MSR MAIR_EL2, <Xt> ; Write Xt to MAIR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1010 | 0010 | 000 |

D7.2.65 MAIR_EL3, Memory Attribute Indirection Register (EL3)

The MAIR_EL3 characteristics are:

Purpose

Provides the memory attribute encodings corresponding to the possible AttrIdx values in a Long-descriptor format translation table entry for stage 1 translations at EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MAIR_EL3 is a 64-bit register.

Field descriptions

The MAIR_EL3 bit assignments are:

MAIR_EL3 is permitted to be cached in a TLB.

Attr<n>, bits [8n+7:8n], for n = 0 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where AttrIdx[2:0] gives the value of <n> in Attr<n>.

Bits [7:4] are encoded as follows:

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 0000 | Device memory. See encoding of Attr<n>[3:0] for the type of Device memory. |
| 00RW, RW not 00 | Normal Memory, Outer Write-Through transient |
| 0100 | Normal Memory, Outer Non-cacheable |
| 01RW, RW not 00 | Normal Memory, Outer Write-Back transient |
| 10RW | Normal Memory, Outer Write-Through non-transient |
| 11RW | Normal Memory, Outer Write-Back non-transient |

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

| Attr<n>[3:0] | Meaning when Attr<n>[7:4] is 0000 | Meaning when Attr<n>[7:4] is not 0000 |
|-----------------|-----------------------------------|--|
| 0000 | Device-nGnRnE memory | UNPREDICTABLE |
| 00RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through transient |
| 0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
| 01RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back transient |
| 1000 | Device-nGRE memory | Normal Memory, Inner Write-Through non-transient (RW=00) |
| 10RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through non-transient |
| 1100 | Device-GRE memory | Normal Memory, Inner Write-Back non-transient (RW=00) |
| 11RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
|--------|-------------|
| 0 | No Allocate |
| 1 | Allocate |

Accessing the MAIR_EL3:

To access the MAIR_EL3:

MRS <Xt>, MAIR_EL3 ; Read MAIR_EL3 into Xt
MSR MAIR_EL3, <Xt> ; Write Xt to MAIR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1010 | 0010 | 000 |

D7.2.66 MIDR_EL1, Main ID Register

The MIDR_EL1 characteristics are:

Purpose

Provides identification information for the PE, including an implementer code for the device and a device ID number.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register MIDR_EL1 is architecturally mapped to AArch32 System register [MIDR](#).

AArch64 System register MIDR_EL1 is architecturally mapped to External register [MIDR_EL1](#).

Attributes

MIDR_EL1 is a 32-bit register.

Field descriptions

The MIDR_EL1 bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

| Hex representation | ASCII representation | Implementer |
|--------------------|----------------------|--|
| 0x41 | A | ARM Limited |
| 0x42 | B | Broadcom Corporation |
| 0x43 | C | Cavium Inc. |
| 0x44 | D | Digital Equipment Corporation |
| 0x49 | I | Infineon Technologies AG |
| 0x4D | M | Motorola or Freescale Semiconductor Inc. |
| 0x4E | N | NVIDIA Corporation |

| Hex representation | ASCII representation | Implementer |
|--------------------|----------------------|------------------------------------|
| 0x50 | P | Applied Micro Circuits Corporation |
| 0x51 | Q | Qualcomm Inc. |
| 0x56 | V | Marvell International Ltd. |
| 0x69 | i | Intel Corporation |

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

| | |
|------|--|
| 0001 | ARMv4 |
| 0010 | ARMv4T |
| 0011 | ARMv5 (obsolete) |
| 0100 | ARMv5T |
| 0101 | ARMv5TE |
| 0110 | ARMv5TEJ |
| 0111 | ARMv6 |
| 1111 | Architectural features are individually identified in the ID_* registers, see Identification registers, functional group on page G4-4194 . |

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the MIDR_EL1:

To access the MIDR_EL1:

MRS <Xt>, MIDR_EL1 ; Read MIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0000 | 000 |

D7.2.67 MPIDR_EL1, Multiprocessor Affinity Register

The MPIDR_EL1 characteristics are:

Purpose

In a multiprocessor system, provides an additional PE identification mechanism for scheduling purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register MPIDR_EL1 is architecturally mapped to AArch32 System register [MPIDR](#).

The assigned value of the [MPIDR](#).{Aff2, Aff1, Aff0} or MPIDR_EL1.{Aff3, Aff2, Aff1, Aff0} set of fields of each PE must be unique within the system as a whole.

In a uniprocessor system ARM recommends that each Aff<n> field of this register returns a value of 0.

Attributes

MPIDR_EL1 is a 64-bit register.

Field descriptions

The MPIDR_EL1 bit assignments are:

Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. Highest level affinity field.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

- 0 Performance of PEs at the lowest affinity level is largely independent.
- 1 Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]

Affinity level 2. Second highest level affinity field.

Aff1, bits [15:8]

Affinity level 1. Third highest level affinity field.

Aff0, bits [7:0]

Affinity level 0. Lowest level affinity field.

Accessing the MPIDR_EL1:

To access the MPIDR_EL1:

MRS <Xt>, MPIDR_EL1 ; Read MPIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0000 | 101 |

D7.2.68 MVFR0_EL1, AArch32 Media and VFP Feature Register 0

The MVFR0_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR1_EL1](#) and [MVFR2_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register MVFR0_EL1 is architecturally mapped to AArch32 System register [MVFR0](#).

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

MVFR0_EL1 is a 32-bit register.

Field descriptions

The MVFR0_EL1 bit assignments are:

| | | | | | | | | |
|---------|---------|--------|----------|--------|-------|------|---------|---|
| 31 | 28 27 | 24 23 | 20 19 | 16 15 | 12 11 | 8 7 | 4 3 | 0 |
| FPRound | FPShVec | FPSqrt | FPDivide | FPTrap | FPDP | FPSP | SIMDReg | |

FPRound, bits [31:28]

Floating-Point Rounding modes. Indicates whether the floating-point implementation provides support for rounding modes. Defined values are:

0000 Not implemented, or only Round to Nearest mode supported, except that Round towards Zero mode is supported for VCVT instructions that always use that rounding mode regardless of the [FPSCR](#) setting.

0001 All rounding modes supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPShVec, bits [27:24]

Short Vectors. Indicates whether the floating-point implementation provides support for the use of short vectors. Defined values are:

- 0000 Short vectors not supported.
- 0001 Short vector operation supported.

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

FPSqrt, bits [23:20]

Square Root. Indicates whether the floating-point implementation provides support for the ARMv6 VFP square root operations. Defined values are:

- 0000 Not supported in hardware.
- 0001 Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The VSQRT.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VSQRT.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPDivide, bits [19:16]

Indicates whether the floating-point implementation provides support for VFP divide operations. Defined values are:

- 0000 Not supported in hardware.
- 0001 Supported.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The VDIV.F32 instruction also requires the single-precision floating-point attribute, bits [7:4], and the VDIV.F64 instruction also requires the double-precision floating-point attribute, bits [11:8].

FPTrap, bits [15:12]

Floating Point Exception Trapping. Indicates whether the floating-point implementation provides support for exception trapping. Defined values are:

- 0000 Not supported.
- 0001 Supported.

All other values are reserved.

A value of 0001 indicates that, when the corresponding trap is enabled, a floating-point exception generates an exception.

FPDP, bits [11:8]

Double Precision. Indicates whether the floating-point implementation provides support for double-precision operations. Defined values are:

- 0000 Not supported in hardware.
- 0001 Supported, VFPv2.
- 0010 Supported, VFPv3, VFPv4, or ARMv8. VFPv3 and ARMv8 add an instruction to load a double-precision floating-point constant, and conversions between double-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

A value of 0b0001 or 0b0010 indicates support for all VFP double-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F64 is only available if the Square root field is 0001.
- VDIV.F64 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the single-precision field is nonzero.

FPSP, bits [7:4]

Single Precision. Indicates whether the floating-point implementation provides support for single-precision operations. Defined values are:

- 0000 Not supported in hardware.
- 0001 Supported, VFPv2.
- 0010 Supported, VFPv3 or VFPv4. VFPv3 adds an instruction to load a single-precision floating-point constant, and conversions between single-precision and fixed-point values.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

A value of 0b0001 or 0b0010 indicates support for all VFP single-precision instructions in the supported version of VFP, except that, in addition to this field being nonzero:

- VSQRT.F32 is only available if the Square root field is 0001.
- VDIV.F32 is only available if the Divide field is 0001.
- Conversion between double-precision and single-precision is only available if the double-precision field is nonzero.

SIMDReg, bits [3:0]

Advanced SIMD registers. Indicates whether the Advanced SIMD and floating-point implementation provides support for the Advanced SIMD and floating-point register bank. Defined values are:

- 0000 The implementation has no Advanced SIMD and floating-point support.
- 0001 The implementation includes floating-point support with 16 x 64-bit registers.
- 0010 The implementation includes Advanced SIMD and floating-point support with 32 x 64-bit registers.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

Accessing the MVFR0_EL1:

To access the MVFR0_EL1:

MRS <Xt>, MVFR0_EL1 ; Read MVFR0_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0011 | 000 |

D7.2.69 MVFR1_EL1, AArch32 Media and VFP Feature Register 1

The MVFR1_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR0_EL1](#) and [MVFR2_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register MVFR1_EL1 is architecturally mapped to AArch32 System register [MVFR1](#).

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

MVFR1_EL1 is a 32-bit register.

Field descriptions

The MVFR1_EL1 bit assignments are:

SIMDFMAC, bits [31:28]

Advanced SIMD Fused Multiply-Accumulate. Indicates whether the Advanced SIMD implementation provides fused multiply accumulate instructions. Defined values are:

0000 Not implemented.

0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

The Advanced SIMD and floating-point implementations must provide the same level of support for these instructions.

FPHP, bits [27:24]

Floating Point Half Precision. Indicates whether the floating-point implementation provides half-precision floating-point conversion instructions. Defined values are:

- 0000 Not implemented.
- 0001 Instructions to convert between half-precision and single-precision implemented.
- 0010 As for 0b0001, and also instructions to convert between half-precision and double-precision implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0010.

SIMDHP, bits [23:20]

Advanced SIMD Half Precision. Indicates whether the Advanced SIMD and floating-point implementation provides half-precision floating-point conversion instructions. Defined values are:

- 0000 Not implemented.
- 0001 Implemented. This value is permitted only if the SIMDSP field is 0001.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDSP, bits [19:16]

Advanced SIMD Single Precision. Indicates whether the Advanced SIMD and floating-point implementation provides single-precision floating-point instructions. Defined values are:

- 0000 Not implemented.
- 0001 Implemented. This value is permitted only if the SIMDInt field is 0001.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDInt, bits [15:12]

Advanced SIMD Integer. Indicates whether the Advanced SIMD and floating-point implementation provides integer instructions. Defined values are:

- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

SIMDLS, bits [11:8]

Advanced SIMD Load/Store. Indicates whether the Advanced SIMD and floating-point implementation provides load/store instructions. Defined values are:

- 0000 Not implemented.
- 0001 Implemented.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPDNAN, bits [7:4]

Default NaN mode. Indicates whether the floating-point implementation provides support only for the Default NaN mode. Defined values are:

- 0000 Not implemented, or hardware supports only the Default NaN mode.
- 0001 Hardware supports propagation of NaN values.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

FPFtZ, bits [3:0]

Flush to Zero mode. Indicates whether the floating-point implementation provides support only for the Flush-to-Zero mode of operation. Defined values are:

0000 Not implemented, or hardware supports only the Flush-to-Zero mode of operation.

0001 Hardware supports full denormalized number arithmetic.

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

Accessing the MVFR1_EL1:

To access the MVFR1_EL1:

MRS <Xt>, MVFR1_EL1 ; Read MVFR1_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0011 | 001 |

D7.2.70 MVFR2_EL1, AArch32 Media and VFP Feature Register 2

The MVFR2_EL1 characteristics are:

Purpose

Describes the features provided by the AArch32 Advanced SIMD and Floating-point implementation.

Must be interpreted with [MVFR0_EL1](#) and [MVFR1_EL1](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page D7-1893](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TID3](#)=1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register MVFR2_EL1 is architecturally mapped to AArch32 System register [MVFR2](#).

In an implementation where at least one Exception level supports execution in AArch32 state, but there is no support for Advanced SIMD and floating-point operation, this register is RAZ.

In an AArch64-only implementation, this register is UNKNOWN.

Attributes

MVFR2_EL1 is a 32-bit register.

Field descriptions

The MVFR2_EL1 bit assignments are:

| | | | | | | |
|----|------|-----|--------|-----|----------|---|
| 31 | RES0 | 8 7 | FPMisc | 4 3 | SIMDMisc | 0 |
|----|------|-----|--------|-----|----------|---|

Bits [31:8]

Reserved, RES0.

FPMisc, bits [7:4]

Indicates whether the floating-point implementation provides support for miscellaneous VFP features.

0000 Not implemented, or no support for miscellaneous features.

0001 Support for Floating-point selection.

0010 As 0001, and Floating-point Conversion to Integer with Directed Rounding modes.

0011 As 0010, and Floating-point Round to Integral Floating-point.

0100 As 0011, and Floating-point MaxNum and MinNum.
All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0100.

SIMDMisc, bits [3:0]

Indicates whether the Advanced SIMD implementation provides support for miscellaneous Advanced SIMD features.

- 0000 Not implemented, or no support for miscellaneous features.
- 0001 Floating-point Conversion to Integer with Directed Rounding modes.
- 0010 As 0001, and Floating-point Round to Integral Floating-point.
- 0011 As 0010, and Floating-point MaxNum and MinNum.

All other values are reserved.
In ARMv8-A the permitted values are 0000 and 0011.

Accessing the MVFR2_EL1:

To access the MVFR2_EL1:

MRS <Xt>, MVFR2_EL1 ; Read MVFR2_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0011 | 010 |

D7.2.71 PAR_EL1, Physical Address Register

The PAR_EL1 characteristics are:

Purpose

Returns the output address (OA) from an address translation instruction that executed successfully, or fault information if the instruction did not execute successfully.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register PAR_EL1 is architecturally mapped to AArch32 System register PAR. RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PAR_EL1 is a 64-bit register.

Field descriptions

The PAR_EL1 bit assignments are:

For all register layouts:

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 0 Address translation completed successfully.
- 1 Address translation aborted.

When PAR_EL1.F=0:

This section describes the register value returned by the successful execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

On a successful conversion, the PAR_EL1 can return a value that indicates the resulting attributes, rather than the values that appear in the translation table descriptors. More precisely:

- The ATTR and SH fields are permitted to report the resulting attributes, as determined by any permitted implementation choices and any applicable configuration bits, instead of reporting the values that appear in the translation table descriptors.

- See the NS bit description for constraints on the value it returns.

ATTR, bits [63:56]

Memory attributes for the returned output address. This field uses the same encoding as the Attr<n> fields in MAIR_EL1, MAIR_EL2, and MAIR_EL3.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Bits [55:48]

Reserved, RES0.

PA, bits [47:12]

Output address. The output address (OA) corresponding to the supplied input address. This field returns address bits[47:12].

For implementations that implement fewer than 48 bits of physical address, the upper bits of this field, corresponding to address bits that are not implemented, are RES0.

Bit [11]

Reserved, RES1.

IMP DEF, bit [10]

IMPLEMENTATION DEFINED.

NS, bit [9]

Non-secure. The NS attribute for a translation table entry from a Secure translation regime.

For a result from a Secure translation regime, this bit reflects the Security state of the physical address space of the translation. This means it reflects the effect of the NSTable bits of earlier levels of the translation table walk if those NSTable bits have an effect on the translation.

For a result from a Non-secure translation regime, this bit is UNKNOWN.

SH, bits [8:7]

Shareability attribute, for the returned output address. Permitted values are:

- | | |
|----|------------------|
| 00 | Non-shareable. |
| 10 | Outer Shareable. |
| 11 | Inner Shareable. |

The value 01 is reserved.

———— **Note** —————

This field returns the value 10 for:

- Any type of Device memory.
- Normal memory with both Inner Non-cacheable and Outer Non-cacheable attributes.

The value returned in this field can be the resulting attribute, as determined by any permitted implementation choices and any applicable configuration bits, instead of the value that appears in the translation table descriptor.

Bits [6:1]

Reserved, RES0.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- | | |
|---|---|
| 0 | Address translation completed successfully. |
|---|---|

When $PAR_EL1.F=1$:

This section describes the register value returned by a fault on the execution of an Address translation instruction. Software might subsequently write a different value to the register, and that write does not affect the operation of the PE.

IMP DEF, bits [63:56]

IMPLEMENTATION DEFINED.

IMP DEF, bits [55:52]

IMPLEMENTATION DEFINED.

IMP DEF, bits [51:48]

IMPLEMENTATION DEFINED.

Bits [47:12]

Reserved, RES0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

S, bit [9]

Indicates the translation stage at which the translation aborted:

- 0 Translation aborted because of a fault in the stage 1 translation.
- 1 Translation aborted because of a fault in the stage 2 translation.

PTW, bit [8]

If this bit is set to 1, it indicates the translation aborted because of a stage 2 fault during a stage 1 translation table walk.

Bit [7]

Reserved, RES0.

FST, bits [6:1]

Fault status code, as shown in the Data Abort ESR encoding.

F, bit [0]

Indicates whether the instruction performed a successful address translation.

- 1 Address translation aborted.

Accessing the PAR_EL1 :

To access the PAR_EL1 :

MRS <Xt>, PAR_EL1 ; Read PAR_EL1 into Xt
MSR PAR_EL1, <Xt> ; Write Xt to PAR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0111 | 0100 | 000 |

D7.2.72 REVIDR_EL1, Revision ID Register

The REVIDR_EL1 characteristics are:

Purpose

Provides implementation-specific minor revision information.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TID1==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register REVIDR_EL1 is architecturally mapped to AArch32 System register [REVIDR](#).

If REVIDR_EL1 has the same value as [MIDR_EL1](#), then its contents have no significance.

Attributes

REVIDR_EL1 is a 32-bit register.

Field descriptions

The REVIDR_EL1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the REVIDR_EL1:

To access the REVIDR_EL1:

MRS <Xt>, REVIDR_EL1 ; Read REVIDR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0000 | 0000 | 110 |

D7.2.73 RMR_EL1, Reset Management Register (if EL2 and EL3 not implemented)

The RMR_EL1 characteristics are:

Purpose

When this register is implemented:

- A write to the register can request a Warm reset.
- If EL1 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 |
|-----|-----|
| - | RW |

However, see [Configurations](#) for information about whether the register is implemented.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register RMR_EL1 is architecturally mapped to AArch32 System register [RMR \(at EL1\)](#).

Only implemented if EL1 is the highest implemented Exception level. In this case:

- If EL1 can use AArch32 and AArch64 then this register must be implemented.
- If EL1 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

RMR_EL1 is a 32-bit register.

Field descriptions

The RMR_EL1 bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When EL1 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL1 cannot use AArch32 this bit is RAO/WI.

When implemented as an RW field, this field resets to 1 on a Cold reset. It is not affected by a Warm reset.

Accessing the RMR_EL1:

To access the RMR_EL1:

MRS <Xt>, RMR_EL1 ; Read RMR_EL1 into Xt
MSR RMR_EL1, <Xt> ; Write Xt to RMR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1100 | 0000 | 010 |

D7.2.74 RMR_EL2, Reset Management Register (if EL2 implemented and EL3 not implemented)

The RMR_EL2 characteristics are:

Purpose

When this register is implemented:

- A write to the register can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

However, see [Configurations](#) for information about whether the register is implemented.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register RMR_EL2 is architecturally mapped to AArch32 System register [HRMR](#).

Only implemented if EL2 is the highest implemented Exception level. In this case:

- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

RMR_EL2 is a 32-bit register.

Field descriptions

The RMR_EL2 bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When EL2 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch32 this bit is RAO/WI.

When implemented as an RW field, this field resets to 1 on a Cold reset. It is not affected by a Warm reset.

Accessing the RMR_EL2:

To access the RMR_EL2:

MRS <Xt>, RMR_EL2 ; Read RMR_EL2 into Xt
MSR RMR_EL2, <Xt> ; Write Xt to RMR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1100 | 0000 | 010 |

D7.2.75 RMR_EL3, Reset Management Register (if EL3 implemented)

The RMR_EL3 characteristics are:

Purpose

When this register is implemented:

- A write to the register can request a Warm reset.
- If EL3 can use AArch32 and AArch64, the register specifies the Execution state that the PE boots into on a Warm reset.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

However, see [Configurations](#) for information about whether the register is implemented.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register RMR_EL3 is architecturally mapped to AArch32 System register [RMR \(at EL3\)](#).

When EL3 is implemented:

- If EL3 can use AArch32 and AArch64 then this register must be implemented.
- If EL3 cannot use AArch32 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

RMR_EL3 is a 32-bit register.

Field descriptions

The RMR_EL3 bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When EL3 can use AArch32, determines which Execution state the PE boots into after a Warm reset:

- 0 AArch32.
- 1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL3 cannot use AArch32 this bit is RAO/WI.

When implemented as an RW field, this field resets to 1 on a Cold reset. It is not affected by a Warm reset.

Accessing the RMR_EL3:

To access the RMR_EL3:

MRS <Xt>, RMR_EL3 ; Read RMR_EL3 into Xt
MSR RMR_EL3, <Xt> ; Write Xt to RMR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1100 | 0000 | 010 |

D7.2.76 RVBAR_EL1, Reset Vector Base Address Register (if EL2 and EL3 not implemented)

The RVBAR_EL1 characteristics are:

Purpose

If EL1 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 |
|-----|-----|
| - | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

Only implemented if the highest Exception level implemented is EL1.

Attributes

RVBAR_EL1 is a 64-bit register.

Field descriptions

The RVBAR_EL1 bit assignments are:

Bits [63:0]

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

Accessing the RVBAR_EL1:

To access the RVBAR_EL1:

MRS <Xt>, RVBAR_EL1 ; Read RVBAR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1100 | 0000 | 001 |

D7.2.77 RVBAR_EL2, Reset Vector Base Address Register (if EL3 not implemented)

The RVBAR_EL2 characteristics are:

Purpose

If EL2 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

Only implemented if the highest Exception level implemented is EL2.

Attributes

RVBAR_EL2 is a 64-bit register.

Field descriptions

The RVBAR_EL2 bit assignments are:

Bits [63:0]

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

Accessing the RVBAR_EL2:

To access the RVBAR_EL2:

MRS <Xt>, RVBAR_EL2 ; Read RVBAR_EL2 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1100 | 0000 | 001 |

D7.2.78 RVBAR_EL3, Reset Vector Base Address Register (if EL3 implemented)

The RVBAR_EL3 characteristics are:

Purpose

If EL3 is the highest Exception level implemented, contains the IMPLEMENTATION DEFINED address that execution starts from after reset when executing in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RO | RO |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

Only implemented if the highest Exception level implemented is EL3.

Attributes

RVBAR_EL3 is a 64-bit register.

Field descriptions

The RVBAR_EL3 bit assignments are:

Bits [63:0]

Reset Address. The IMPLEMENTATION DEFINED address that execution starts from after reset when executing in 64-bit state. Bits[1:0] of this register are 00, as this address must be aligned, and the address must be within the physical address size supported by the PE.

Accessing the RVBAR_EL3:

To access the RVBAR_EL3:

MRS <Xt>, RVBAR_EL3 ; Read RVBAR_EL3 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1100 | 0000 | 001 |

D7.2.79 S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED registers

The S3_<op1>_<Cn>_<Cm>_<op2> characteristics are:

Purpose

This area of the instruction set space is reserved for IMPLEMENTATION DEFINED registers.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|---------|----------|---------|----------|----------------|----------------|
| IMP DEF | IMP DEF | IMP DEF | IMP DEF | IMP DEF | IMP DEF |

The numbers in these register names are encoded in decimal without leading zeroes, and the Cn and Cm fields require a literal C before the number. For example, S3_4_C11_C9_7.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If HCR_EL2.TIDCP==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

There are no configuration notes.

Attributes

S3_<op1>_<Cn>_<Cm>_<op2> is a 64-bit register.

Field descriptions

The S3_<op1>_<Cn>_<Cm>_<op2> bit assignments are:

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

Accessing the S3_<op1>_<Cn>_<Cm>_<op2>:

To access the S3_<op1>_<Cn>_<Cm>_<op2>:

MRS <Xt>, S3_<op1>_<Cn>_<Cm>_<op2> ; Read S3_<op1>_<Cn>_<Cm>_<op2> into Xt
MSR S3_<op1>_<Cn>_<Cm>_<op2>, <Xt> ; Write Xt to S3_<op1>_<Cn>_<Cm>_<op2>

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | xxx | 1x11 | xxxx | xxx |

The value of <Cn> must be either 11 or 15. Other values may refer to architecturally-defined registers.

D7.2.80 SCR_EL3, Secure Configuration Register

The SCR_EL3 characteristics are:

Purpose

Defines the configuration of the current Security state. It specifies:

- The Security state of EL0 and EL1, either Secure or Non-secure.
- The Execution state at lower Exception levels.
- Whether IRQ, FIQ, and External Abort interrupts are taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register SCR_EL3 can be mapped to AArch32 System register SCR, but this is not architecturally mandated.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCR_EL3 is a 32-bit register.

Field descriptions

The SCR_EL3 bit assignments are:

Bits [31:14]

Reserved, RES0.

TWE, bit [13]

Traps EL2, EL1, and EL0 execution of WFE instructions to EL3, from both Security states and both Execution states.

- | | |
|---|---|
| 0 | EL2, EL1, and EL0 execution of WFE instructions is not trapped to EL3. |
| 1 | Any attempt to execute a WFE instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state. |

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

TWI, bit [12]

Traps EL2, EL1, and EL0 execution of WFI instructions to EL3, from both Security states and both Execution states.

- | | |
|---|---|
| 0 | EL2, EL1, and EL0 execution of WFI instructions is not trapped to EL3. |
| 1 | Any attempt to execute a WFI instruction at any Exception level lower than EL3 is trapped to EL3, if the instruction would otherwise have caused the PE to enter a low-power state. |

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

ST, bit [11]

Traps Secure EL1 accesses to the Counter-timer Physical Secure timer registers to EL3, from AArch64 state only.

- | | |
|---|--|
| 0 | Secure EL1 using AArch64 accesses to the CNTPS_TVAL_EL1 , CNTPS_CTL_EL1 , and CNTPS_CVAL_EL1 are trapped to EL3. |
| 1 | Secure EL1 using AArch64 accesses to the CNTPS_TVAL_EL1 , CNTPS_CTL_EL1 , and CNTPS_CVAL_EL1 are not trapped to EL3. |

RW, bit [10]

Execution state control for lower Exception levels.

- | | |
|---|--|
| 0 | Lower levels are all AArch32. |
| 1 | The next lower level is AArch64. If EL2 is present: <ul style="list-style-type: none">• EL2 is AArch64.• EL2 controls EL1 and EL0 behaviors. If EL2 is not present: <ul style="list-style-type: none">• EL1 is AArch64.• EL0 is determined by the Execution state described in the current process state when executing at EL0. |

If all lower exception levels cannot use AArch32 then this bit is RAO/WI.

This bit is permitted to be cached in a TLB.

SIF, bit [9]

Secure instruction fetch. When the PE is in Secure state, this bit disables instruction fetch from Non-secure memory. The possible values for this bit are:

- 0 Secure state instruction fetches from Non-secure memory are permitted.
- 1 Secure state instruction fetches from Non-secure memory are not permitted.

This bit is permitted to be cached in a TLB.

HCE, bit [8]

Hypervisor Call instruction enable. Enables HVC instructions at EL3, EL2, and Non-secure EL1, in both Execution states.

- 0 HVC instructions are UNDEFINED at EL3, EL2, and Non-secure EL1, and any resulting exception is taken from the current Exception level to the current Exception level.
- 1 HVC instructions are enabled at EL1 and above.

———— **Note** ————

HVC instructions are always UNDEFINED at EL0.

If EL2 is not implemented, this bit is RES0.

SMD, bit [7]

Secure Monitor Call disable. Disables SMC instructions at EL1 and above, from both Security states and both Execution states.

- 0 SMC instructions are enabled at EL1 and above.
- 1 SMC instructions are UNDEFINED at EL1 and above.

———— **Note** ————

SMC instructions are always UNDEFINED at EL0.

Bit [6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

EA, bit [3]

External Abort and SError Interrupt Routing.

- 0 When executing at Exception levels below EL3, External Aborts and SError Interrupts are not taken to EL3.
In addition, when executing at EL3:
 - SError Interrupts are not taken.
 - External Aborts are taken to EL3.
- 1 When executing at any Exception level, External Aborts and SError Interrupts are taken to EL3.

For more information, see [Asynchronous exception routing on page D1-1556](#).

FIQ, bit [2]

Physical FIQ Routing.

- 0 When executing at Exception levels below EL3, physical FIQ interrupts are not taken to EL3.

When executing at EL3, physical FIQ interrupts are not taken.

- 1 When executing at any Exception level, physical FIQ interrupts are taken to EL3.
For more information, see [Asynchronous exception routing](#) on page D1-1556.

IRQ, bit [1]

Physical IRQ Routing.

- 0 When executing at Exception levels below EL3, physical IRQ interrupts are not taken to EL3.
When executing at EL3, physical IRQ interrupts are not taken.
- 1 When executing at any Exception level, physical IRQ interrupts are taken to EL3.
For more information, see [Asynchronous exception routing](#) on page D1-1556.

NS, bit [0]

Non-secure bit.

- 0 Indicates that EL0 and EL1 are in Secure state, and so memory accesses from those Exception levels can access Secure memory.
When executing at EL3:
- The [AT S1E2R](#), [AT S1E2W](#), [TLBI VAE2](#), [TLBI VALE2](#), [TLBI VAE2IS](#), [TLBI VALE2IS](#), [TLBI ALLE2](#), and [TLBI ALLE2IS](#) System instructions are UNDEFINED.
 - Each AT S1E* System instruction executes as the corresponding AT S1E* instruction. For example, [AT S1E0R](#) executes as [AT S1E0R](#).
 - Each of the [TLBI IPAS2E1](#), [TLBI IPAS2E1IS](#), [TLBI IPAS2LE1](#), and [TLBI IPAS2LE1IS](#) System instructions executes as a NOP.
 - A [TLBI VMALLS12E1](#) System instruction executes as [TLBI VMALLE1](#), and a [TLBI VMALLS12E1IS](#) System instruction executes as [TLBI VMALLE1IS](#).
- 1 Indicates that EL0 and EL1 are in Non-secure state, and so memory accesses from those Exception levels cannot access Secure memory.

Note

EL2 is not supported in the Secure state. When `SCR_EL3.NS==0`, it is not possible to enter EL2, and the EL2 state has no effect on execution. See [Virtualization](#) on page D1-1504.

Accessing the SCR_EL3:

To access the SCR_EL3:

MRS <Xt>, SCR_EL3 ; Read SCR_EL3 into Xt
MSR SCR_EL3, <Xt> ; Write Xt to SCR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0001 | 000 |

D7.2.81 SCTLR_EL1, System Control Register (EL1)

The SCTLR_EL1 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL1 and EL0.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register SCTLR_EL1 is architecturally mapped to AArch32 System register [SCTLR](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL1 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCTLR_EL1 is a 32-bit register.

Field descriptions

The SCTLR_EL1 bit assignments are:

Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bit [27]

Reserved, RES0.

UCI, bit [26]

Traps EL0 execution of cache maintenance instructions to EL1, from AArch64 state only.

0 Any attempt to execute a **DC CVAU**, **DC CIVAC**, **DC CVAC**, or **IC IVAU** instruction at EL0 using AArch64 is trapped to EL1.

1 Does not cause any instruction to be trapped.

This field resets to a value that is architecturally UNKNOWN.

EE, bit [25]

Endianness of data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime.

The possible values of this bit are:

0 Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are little-endian.

1 Explicit data accesses at EL1, and stage 1 translation table walks in the EL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

E0E, bit [24]

Endianness of data accesses at EL0.

The possible values of this bit are:

0 Explicit data accesses at EL0 are little-endian.

1 Explicit data accesses at EL0 are big-endian.

If an implementation only supports Little-endian accesses at EL0 then this bit is RES0. This option is not permitted when SCTLR_EL1.EE is RES1.

If an implementation only supports Big-endian accesses at EL0 then this bit is RES1. This option is not permitted when SCTLR_EL1.EE is RES0.

This bit has no effect on the endianness of LDTR, LDTRH, LDTRSH, LDTRSW, STTR and STTRH instructions executed at EL1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [23:22]

Reserved, RES1.

Bit [21]

Reserved, RES0.

Bit [20]

Reserved, RES1.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL1&0 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- 0 This control has no effect on memory access permissions.
- 1 Any region that is writable in the EL1&0 translation regime is forced to XN for accesses from software executing at EL1 or EL0.

The WXN bit is permitted to be cached in a TLB.

This field resets to a value that is architecturally UNKNOWN.

nTWE, bit [18]

Traps EL0 execution of WFE instructions to EL1, from both Execution states.

- 0 Any attempt to execute a WFE instruction at EL0 is trapped to EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
- 1 EL0 execution of WFE instructions is not trapped to EL1.

In AArch32 state, the attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

—————
This field resets to a value that is architecturally UNKNOWN.

Bit [17]

Reserved, RES0.

nTWI, bit [16]

Traps EL0 execution of WFI instructions to EL1, from both Execution states.

- 0 Any attempt to execute a WFI instruction at EL0 is trapped EL1, if the instruction would otherwise have caused the PE to enter a low-power state.
- 1 EL0 execution of WFI instructions is not trapped to EL1.

In AArch32 state, the attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE of WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

—————
This field resets to a value that is architecturally UNKNOWN.

UCT, bit [15]

Traps EL0 accesses to the [CTR_EL0](#) to EL1, from AArch64 state only.

- 0 Accesses to the [CTR_EL0](#) from EL0 using AArch64 are trapped to EL1.
- 1 Accesses to the [CTR_EL0](#) from EL0 using AArch64 are not trapped to EL1.

This field resets to a value that is architecturally UNKNOWN.

DZE, bit [14]

Traps EL0 execution of [DC ZVA](#) instructions to EL1, from AArch64 state only.

- 0 Any attempt to execute a [DC ZVA](#) instruction at EL0 using AArch64 is trapped to EL1. Reading [DCZID_EL0.DZP](#) from EL0 returns 1, indicating that [DC ZVA](#) instructions are not supported.
- 1 EL0 execution of [DC ZVA](#) instructions is not trapped to EL1.

This field resets to a value that is architecturally UNKNOWN.

Bit [13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL0 and EL1:

- 0 All instruction access to Normal memory from EL0 and EL1 are Non-cacheable for all levels of instruction and unified cache.
If the value of [SCTLR_EL1.M](#) is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
- 1 This control has no effect on the Cacheability of instruction access to Normal memory from EL0 and EL1.
If the value of [SCTLR_EL1.M](#) is 0, instruction accesses from stage 1 of the EL1&0 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

When the value of the [HCR_EL2.DC](#) bit is 1, then instruction access to Normal memory from EL0 and EL1 are Cacheable regardless of the value of the [SCTLR_EL1.I](#) bit.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bit [10]

Reserved, RES0.

UMA, bit [9]

User Mask Access. Traps EL0 execution of MSR and MRS instructions that access the PSTATE.{D, A, I, F} masks to EL1, from AArch64 state only.

- 0 Any attempt at EL0 using AArch64 to execute an MRS, MSR(register), or MSR(immediate) instruction that accesses the [DAIF](#) is trapped to EL1.
- 1 EL0 execution of MRS, MSR(register), or MSR(immediate) instructions that access the [DAIF](#) is not trapped to EL1.

This field resets to a value that is architecturally UNKNOWN.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at EL0 using AArch32.

- 0 SETEND instruction execution is enabled at EL0 using AArch32.
- 1 SETEND instructions are UNDEFINED at EL0 using AArch32.

If the implementation does not support mixed-endian operation at any Exception level, this bit is RES1.

If EL0 cannot use AArch32, this bit is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at EL0 using AArch32.

- | | |
|---|--|
| 0 | All IT instruction functionality is enabled at EL0 using AArch32. |
| 1 | Any attempt at EL0 using AArch32 to execute any of the following is UNDEFINED: <ul style="list-style-type: none"> • All encodings of the IT instruction with hw1[3:0]!=1000. • All encodings of the subsequent instruction with the following values for hw1: <ul style="list-style-type: none"> 11xxxxxxxxxxxx <li style="padding-left: 40px;">All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM. 1011xxxxxxxxxxxx <li style="padding-left: 40px;">All instructions in Miscellaneous 16-bit instructions on page F3-2442. 10100xxxxxxxxxxx <li style="padding-left: 40px;">ADD Rd, PC, #imm 01001xxxxxxxxxxx <li style="padding-left: 40px;">LDR Rd, [PC, #imm] 0100x1xxx1111xxx <li style="padding-left: 40px;">ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC. 010001xx1xxxx111 <li style="padding-left: 40px;">ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn. |

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see [Changes to an ITD control by an instruction in an IT block on page E1-2298](#).

If EL0 cannot use AArch32, this bit is RES1.

ITD is optional, but if it is implemented in the [SCTLR](#) then it must also be implemented in the [SCTLR_EL1](#). If it is not implemented then this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from EL0:

- | | |
|---|--|
| 0 | EL0 using AArch32: EL0 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is UNDEFINED. |
| 1 | EL0 using AArch32: EL0 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is enabled. |

If EL0 cannot use AArch32, this bit is RES0.

CP15BEN is optional, but if it is implemented in the [SCTLR](#) then it must also be implemented in the [SCTLR_EL1](#). If it is not implemented then this bit is RAO/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

SA0, bit [4]

SP Alignment check enable for EL0. When set to 1, if a load or store instruction executed at EL0 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-1515](#).

This field resets to a value that is architecturally UNKNOWN.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL1 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-1515](#).

This field resets to a value that is architecturally UNKNOWN.

C, bit [2]

Cacheability control, for data accesses.

0 All data access to Normal memory from EL0 and EL1, and all Normal memory accesses to the EL1&0 stage 1 translation tables, are Non-cacheable for all levels of data and unified cache.

1 This control has no effect on the Cacheability of:

- Data access to Normal memory from EL0 and EL1.
- Normal memory accesses to the EL1&0 stage 1 translation tables.

When the value of the [HCR_EL2.DC](#) bit is 1, the PE ignores [SCLTR.C](#). This means that Non-secure EL0 and Non-secure EL1 data accesses to Normal memory are Cacheable.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL1 and EL0:

0 Alignment fault checking disabled when executing at EL1 or EL0.

Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.

1 Alignment fault checking enabled when executing at EL1 or EL0.

All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL1 and EL0 stage 1 address translation. Possible values of this bit are:

0 EL1 and EL0 stage 1 address translation disabled.

See the [SCTLR_EL1.I](#) field for the behavior of instruction accesses to Normal memory.

1 EL1 and EL0 stage 1 address translation enabled.

If the value of [HCR_EL2.{DC, TGE}](#) is not {0, 0} then in Non-secure state the PE behaves as if the value of the [SCTLR_EL1.M](#) field is 0 for all purposes other than returning the value of a direct read of the field.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCTLR_EL1:

To access the SCTLR_EL1:

MRS <Xt>, SCTLR_EL1 ; Read SCTLR_EL1 into Xt
MSR SCTLR_EL1, <Xt> ; Write Xt to SCTLR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0001 | 0000 | 000 |

D7.2.82 SCTLR_EL2, System Control Register (EL2)

The SCTLR_EL2 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register SCTLR_EL2 is architecturally mapped to AArch32 System register [HSCTLR](#).

If EL2 is not implemented, this register is RES0 from EL3.

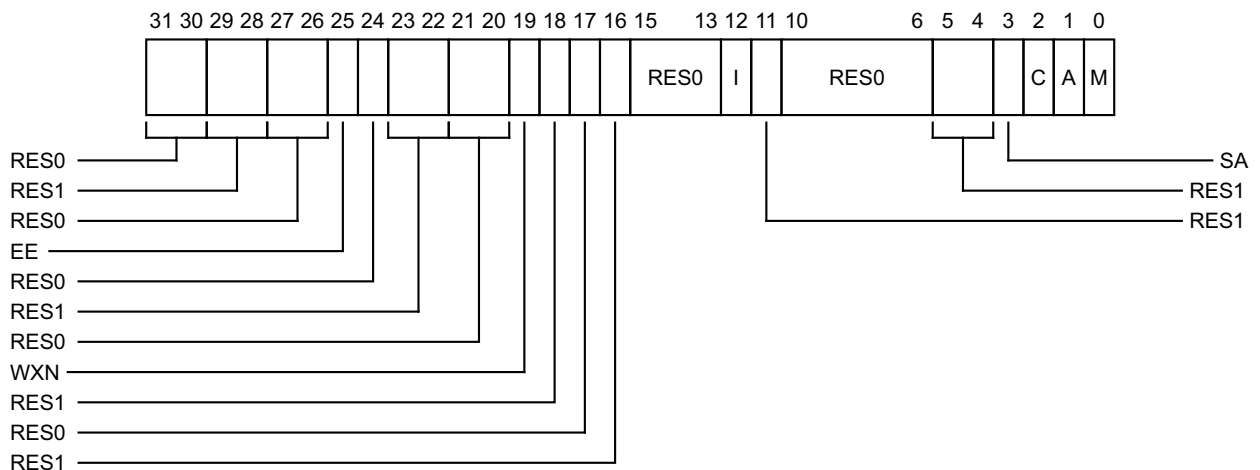

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCTLR_EL2 is a 32-bit register.

Field descriptions

The SCTLR_EL2 bit assignments are:

Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Endianness of data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime.

The possible values of this bit are:

- 0 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are little-endian.
- 1 Explicit data accesses at EL2, stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the EL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- 0 This control has no effect on memory access permissions.
- 1 Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

This field resets to a value that is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

- 0 All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTL_R_EL2.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
- 1 This control has no effect on the Cacheability of instruction access to Normal memory from EL2.
If the value of SCTL_R_EL2.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL3 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL2 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-1515](#).

This field resets to a value that is architecturally UNKNOWN.

C, bit [2]

Cacheability control, for data accesses.

- 0 All data access to Normal memory from EL2, and all Normal memory accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.
- 1 This control has no effect on the Cacheability of:
- Data access to Normal memory from EL2.
 - Normal memory accesses to the EL2 translation tables.

This bit has no effect on the EL1&0 or EL3 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

- 0 Alignment fault checking disabled when executing at EL2.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
- 1 Alignment fault checking enabled when executing at EL2.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

- 0 EL2 stage 1 address translation disabled.
See the SCTLR_EL2.I field for the behavior of instruction accesses to Normal memory.
- 1 EL2 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCTLR_EL2:

To access the SCTLR_EL2:

MRS <Xt>, SCTLR_EL2 ; Read SCTLR_EL2 into Xt
MSR SCTLR_EL2, <Xt> ; Write Xt to SCTLR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0000 | 000 |

D7.2.83 SCTLR_EL3, System Control Register (EL3)

The SCTLR_EL3 characteristics are:

Purpose

Provides top level control of the system, including its memory system, at EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

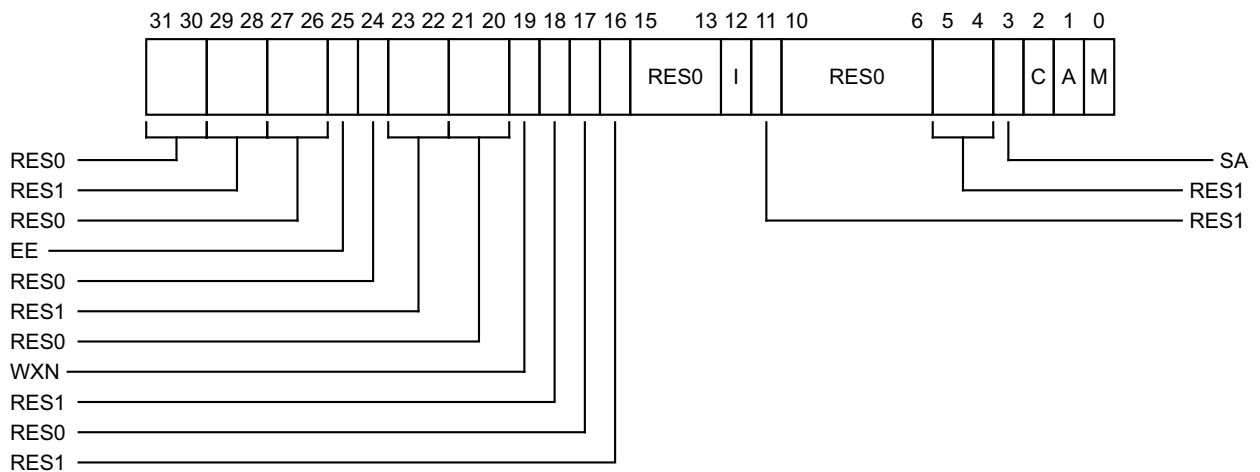

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL3 using AArch64. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SCTLR_EL3 is a 32-bit register.

Field descriptions

The SCTLR_EL3 bit assignments are:

Bits [31:30]

Reserved, RES0.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

Endianness of data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime.

The possible values of this bit are:

- 0 Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are little-endian.
- 1 Explicit data accesses at EL3, and stage 1 translation table walks in the EL3 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

The EE bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL3 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- 0 This control has no effect on memory access permissions.
- 1 Any region that is writable in the EL3 translation regime is forced to XN for accesses from software executing at EL3.

The WXN bit is permitted to be cached in a TLB.

This field resets to a value that is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL3:

- 0 All instruction access to Normal memory from EL3 are Non-cacheable for all levels of instruction and unified cache.
If the value of SCTL_R_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.

- 1 This control has no effect on the Cacheability of instruction access to Normal memory from EL3.
If the value of SCTLR_EL3.M is 0, instruction accesses from stage 1 of the EL3 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the EL1&0 or EL2 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:6]

Reserved, RES0.

Bits [5:4]

Reserved, RES1.

SA, bit [3]

SP Alignment check enable. When set to 1, if a load or store instruction executed at EL3 uses the SP as the base address and the SP is not aligned to a 16-byte boundary, then a SP alignment fault exception is generated. For more information, see [SP alignment checking on page D1-1515](#).

This field resets to a value that is architecturally UNKNOWN.

C, bit [2]

Cacheability control, for data accesses.

- 0 All data access to Normal memory from EL3, and all Normal memory accesses to the EL3 translation tables, are Non-cacheable for all levels of data and unified cache.
- 1 This control has no effect on the Cacheability of:
- Data access to Normal memory from EL3.
 - Normal memory accesses to the EL3 translation tables.

This bit has no effect on the EL1&0 or EL2 translation regimes.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL3:

- 0 Alignment fault checking disabled when executing at EL3.
Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element(s) being accessed.
- 1 Alignment fault checking enabled when executing at EL3.
All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element(s) being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL3 stage 1 address translation. Possible values of this bit are:

- 0 EL3 stage 1 address translation disabled.
See the SCTLR_EL3.I field for the behavior of instruction accesses to Normal memory.
- 1 EL3 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the SCTL_R_EL3:

To access the SCTL_R_EL3:

MRS <Xt>, SCTL_R_EL3 ; Read SCTL_R_EL3 into Xt
MSR SCTL_R_EL3, <Xt> ; Write Xt to SCTL_R_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0000 | 000 |

D7.2.84 TCR_EL1, Translation Control Register (EL1)

The TCR_EL1 characteristics are:

Purpose

Determines which of the Translation Table Base Registers defines the base address for a translation table walk required for the stage 1 translation of a memory access from EL0 or EL1. Also controls the translation table format and holds cacheability and shareability information.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Any of the bits in TCR_EL1 are permitted to be cached in a TLB.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register TCR_EL1[31:0] is architecturally mapped to AArch32 System register [TTBCR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL1 is a 64-bit register.

Field descriptions

The TCR_EL1 bit assignments are:

Bits [63:39]

Reserved, RES0.

TBI1, bit [38]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the [TTBR1_EL1](#) region, or ignored and used for tagged addresses. Defined values are:

- 0 Top Byte used in the address calculation.
- 1 Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by [TTBR1_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI1 is 1 and bit [55] of the target address is 1, caused by:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 1 before it is stored in the PC.

TBI0, bit [37]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the [TTBR0_EL1](#) region, or ignored and used for tagged addresses. Defined values are:

- 0 Top Byte used in the address calculation.
- 1 Top Byte ignored in the address calculation.

This affects addresses generated in EL0 and EL1 using AArch64 where the address would be translated by tables pointed to by [TTBR0_EL1](#). It has an effect whether the EL1&0 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI0 is 1 and bit [55] of the target address is 0, caused by:

- A branch or procedure return within EL0 or EL1.
- An exception taken to EL1.
- An exception return to EL0 or EL1.

In these cases bits [63:56] of the address are also set to 0 before it is stored in the PC.

AS, bit [36]

ASID Size. Defined values are:

- 0 8 bit - the upper 8 bits of [TTBR0_EL1](#) and [TTBR1_EL1](#) are ignored by hardware for every purpose except reading back the register, and are treated as if they are all zeros for when used for allocation and matching entries in the TLB.
- 1 16 bit - the upper 16 bits of [TTBR0_EL1](#) and [TTBR1_EL1](#) are used for allocation and matching in the TLB.

If the implementation has only 8 bits of ASID, this field is RES0.

Bit [35]

Reserved, RES0.

IPS, bits [34:32]

Intermediate Physical Address Size.

- 000 32 bits, 4GB.
- 001 36 bits, 64GB.
- 010 40 bits, 1TB.
- 011 42 bits, 4TB.
- 100 44 bits, 16TB.
- 101 48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG1, bits [31:30]

Granule size for the [TTBR1_EL1](#).

| | |
|----|------|
| 01 | 16KB |
| 10 | 4KB |
| 11 | 64KB |

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH1, bits [29:28]

Shareability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

Defined values are:

| | |
|----|-----------------|
| 00 | Non-shareable |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-5492](#).

ORGN1, bits [27:26]

Outer cacheability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

| | |
|----|--|
| 00 | Normal memory, Outer Non-cacheable |
| 01 | Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable |

IRGN1, bits [25:24]

Inner cacheability attribute for memory associated with translation table walks using [TTBR1_EL1](#).

| | |
|----|--|
| 00 | Normal memory, Inner Non-cacheable |
| 01 | Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable |

EPD1, bit [23]

Translation table walk disable for translations using [TTBR1_EL1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR1_EL1](#). The encoding of this bit is:

| | |
|---|--|
| 0 | Perform translation table walks using TTBR1_EL1 . |
| 1 | A TLB miss on an address that is translated using TTBR1_EL1 generates a Translation fault. No translation table walk is performed. |

A1, bit [22]

Selects whether [TTBR0_EL1](#) or [TTBR1_EL1](#) defines the ASID. The encoding of this bit is:

- | | |
|---|---|
| 0 | TTBR0_EL1 .ASID defines the ASID. |
| 1 | TTBR1_EL1 .ASID defines the ASID. |

T1SZ, bits [21:16]

The size offset of the memory region addressed by [TTBR1_EL1](#). The region size is $2^{(64-T1SZ)}$ bytes.

The maximum and minimum possible values for T1SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

TG0, bits [15:14]

Granule size for the [TTBR0_EL1](#).

- | | |
|----|------|
| 00 | 4KB |
| 01 | 64KB |
| 10 | 16KB |

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

- | | |
|----|-----------------|
| 00 | Non-shareable |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

- | | |
|----|--|
| 00 | Normal memory, Outer Non-cacheable |
| 01 | Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable |

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [TTBR0_EL1](#).

- | | |
|----|--|
| 00 | Normal memory, Inner Non-cacheable |
| 01 | Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable |

EPD0, bit [7]

Translation table walk disable for translations using [TTBR0_EL1](#). This bit controls whether a translation table walk is performed on a TLB miss, for an address that is translated using [TTBR0_EL1](#). The encoding of this bit is:

- 0 Perform translation table walks using [TTBR0_EL1](#).
- 1 A TLB miss on an address that is translated using [TTBR0_EL1](#) generates a Translation fault. No translation table walk is performed.

Bit [6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by [TTBR0_EL1](#). The region size is $2^{(64-T0SZ)}$ bytes. The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL1:

To access the TCR_EL1:

MRS <Xt>, TCR_EL1 ; Read TCR_EL1 into Xt
MSR TCR_EL1, <Xt> ; Write Xt to TCR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0010 | 0000 | 010 |

D7.2.85 TCR_EL2, Translation Control Register (EL2)

The TCR_EL2 characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from EL2, and holds cacheability and shareability information for the accesses.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Any of the bits in TCR_EL2 are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TCR_EL2 is architecturally mapped to AArch32 System register [HTCR](#).

If EL2 is not implemented, this register is RES0 from EL3.

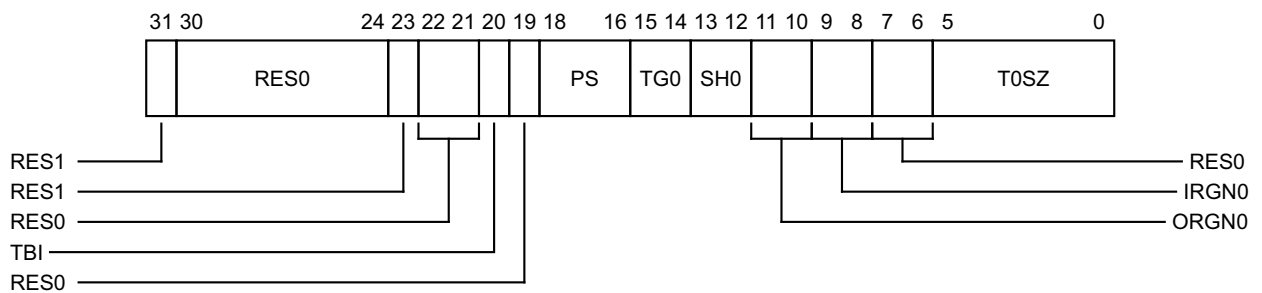

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL2 is a 32-bit register.

Field descriptions

The TCR_EL2 bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the [TTBR0_EL2](#) region, or ignored and used for tagged addresses.

0 Top Byte used in the address calculation.

1 Top Byte ignored in the address calculation.

This affects addresses generated in EL2 using AArch64 where the address would be translated by tables pointed to by [TTBR0_EL2](#). It has an effect whether the EL2 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI is 1, caused by:

- A branch or procedure return within EL2.
- An exception taken to EL2.
- An exception return to EL2.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

000 32 bits, 4GB.

001 36 bits, 64GB.

010 40 bits, 1TB.

011 42 bits, 4TB.

100 44 bits, 16TB.

101 48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the [TTBR0_EL2](#).

00 4KB

01 64KB

10 16KB

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [TTBR0_EL2](#).

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [TTBR0_EL2](#).

- 00 Normal memory, Outer Non-cacheable
- 01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [TTBR0_EL2](#).

- 00 Normal memory, Inner Non-cacheable
- 01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

Bits [7:6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by [TTBR0_EL2](#). The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL2:

To access the TCR_EL2:

MRS <Xt>, TCR_EL2 ; Read TCR_EL2 into Xt
MSR TCR_EL2, <Xt> ; Write Xt to TCR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0010 | 0000 | 010 |

D7.2.86 TCR_EL3, Translation Control Register (EL3)

The TCR_EL3 characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from EL3, and holds cacheability and shareability information for the accesses.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Any of the bits in TCR_EL3 are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TCR_EL3 is a 32-bit register.

Field descriptions

The TCR_EL3 bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:21]

Reserved, RES0.

TBI, bit [20]

Top Byte ignored - indicates whether the top byte of an address is used for address match for the [TTBR0_EL3](#) region, or ignored and used for tagged addresses.

0 Top Byte used in the address calculation.

1 Top Byte ignored in the address calculation.

This affects addresses generated in EL3 using AArch64 where the address would be translated by tables pointed to by [TTBR0_EL3](#). It has an effect whether the EL3 translation regime is enabled or not.

Additionally, this affects changes to the program counter, when TBI is 1, caused by:

- A branch or procedure return within EL3.
- A exception taken to EL3.
- An exception return to EL3.

In these cases bits [63:56] of the address are set to 0 before it is stored in the PC.

Bit [19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

000 32 bits, 4GB.

001 36 bits, 64GB.

010 40 bits, 1TB.

011 42 bits, 4TB.

100 44 bits, 16TB.

101 48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the [TTBR0_EL3](#).

00 4KB

01 64KB

10 16KB

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [TTBR0_EL3](#).

00 Non-shareable

10 Outer Shareable

11 Inner Shareable

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [TTBR0_EL3](#).

- 00 Normal memory, Outer Non-cacheable
- 01 Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [TTBR0_EL3](#).

- 00 Normal memory, Inner Non-cacheable
- 01 Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable
- 10 Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable
- 11 Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable

Bits [7:6]

Reserved, RES0.

T0SZ, bits [5:0]

The size offset of the memory region addressed by [TTBR0_EL3](#). The region size is $2^{(64-T0SZ)}$ bytes.

The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

Accessing the TCR_EL3:

To access the TCR_EL3:

MRS <Xt>, TCR_EL3 ; Read TCR_EL3 into Xt
MSR TCR_EL3, <Xt> ; Write Xt to TCR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0010 | 0000 | 010 |

D7.2.87 TPIDR_EL0, EL0 Read/Write Software Thread ID Register

The TPIDR_EL0 characteristics are:

Purpose

Provides a location where software executing at EL0 can store thread identifying information, for OS management purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RW | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TPIDR_EL0[31:0] is architecturally mapped to AArch32 System register [TPIDRURW](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL0 is a 64-bit register.

Field descriptions

The TPIDR_EL0 bit assignments are:

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDR_EL0:

To access the TPIDR_EL0:

```
MRS <Xt>, TPIDR_EL0 ; Read TPIDR_EL0 into Xt
MSR TPIDR_EL0, <Xt> ; Write Xt to TPIDR_EL0
```

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1101 | 0000 | 010 |

D7.2.88 TPIDR_EL1, EL1 Software Thread ID Register

The TPIDR_EL1 characteristics are:

Purpose

Provides a location where software executing at EL1 can store thread identifying information, for OS management purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TPIDR_EL1[31:0] is architecturally mapped to AArch32 System register [TPIDRPRW](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL1 is a 64-bit register.

Field descriptions

The TPIDR_EL1 bit assignments are:

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDR_EL1:

To access the TPIDR_EL1:

MRS <Xt>, TPIDR_EL1 ; Read TPIDR_EL1 into Xt
MSR TPIDR_EL1, <Xt> ; Write Xt to TPIDR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1101 | 0000 | 100 |

D7.2.89 TPIDR_EL2, EL2 Software Thread ID Register

The TPIDR_EL2 characteristics are:

Purpose

Provides a location where software executing at EL2 can store thread identifying information, for OS management purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TPIDR_EL2[31:0] is architecturally mapped to AArch32 System register [HTPIDR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL2 is a 64-bit register.

Field descriptions

The TPIDR_EL2 bit assignments are:

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDR_EL2:

To access the TPIDR_EL2:

MRS <Xt>, TPIDR_EL2 ; Read TPIDR_EL2 into Xt
MSR TPIDR_EL2, <Xt> ; Write Xt to TPIDR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1101 | 0000 | 010 |

D7.2.90 TPIDR_EL3, EL3 Software Thread ID Register

The TPIDR_EL3 characteristics are:

Purpose

Provides a location where software executing at EL3 can store thread identifying information, for OS management purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDR_EL3 is a 64-bit register.

Field descriptions

The TPIDR_EL3 bit assignments are:

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDR_EL3:

To access the TPIDR_EL3:

MRS <Xt>, TPIDR_EL3 ; Read TPIDR_EL3 into Xt
MSR TPIDR_EL3, <Xt> ; Write Xt to TPIDR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1101 | 0000 | 010 |

D7.2.91 TPIDRRO_EL0, EL0 Read-Only Software Thread ID Register

The TPIDRRO_EL0 characteristics are:

Purpose

Provides a location where software executing at EL1 or higher can store thread identifying information that is visible to software executing at EL0, for OS management purposes.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RO | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TPIDRRO_EL0[31:0] is architecturally mapped to AArch32 System register [TPIDRURO](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TPIDRRO_EL0 is a 64-bit register.

Field descriptions

The TPIDRRO_EL0 bit assignments are:

Bits [63:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the TPIDRRO_EL0:

To access the TPIDRRO_EL0:

MRS <Xt>, TPIDRRO_EL0 ; Read TPIDRRO_EL0 into Xt
MSR TPIDRRO_EL0, <Xt> ; Write Xt to TPIDRRO_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1101 | 0000 | 011 |

D7.2.92 TTBR0_EL1, Translation Table Base Register 0 (EL1)

The TTBR0_EL1 characteristics are:

Purpose

Holds the base address of translation table 0, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HCR_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register TTBR0_EL1 is architecturally mapped to AArch32 System register [TTBR0](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL1 is a 64-bit register.

Field descriptions

The TTBR0_EL1 bit assignments are:

ASID, bits [63:48]

An ASID for the translation table base address. The [TCR_EL1.A1](#) field selects either TTBR0_EL1.ASID or TTBR1_EL1.ASID.

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.

- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of `TCR_EL1.TOSZ`, the stage of translation, and the translation granule size.

Accessing the TTBR0_EL1:

To access the TTBR0_EL1:

MRS <Xt>, TTBR0_EL1 ; Read TTBR0_EL1 into Xt
MSR TTBR0_EL1, <Xt> ; Write Xt to TTBR0_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0010 | 0000 | 000 |

D7.2.93 TTBR0_EL2, Translation Table Base Register 0 (EL2)

The TTBR0_EL2 characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register TTBR0_EL2 is architecturally mapped to AArch32 System register [HTTBR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL2 is a 64-bit register.

Field descriptions

The TTBR0_EL2 bit assignments are:

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of [TCR_EL2.T0SZ](#), the stage of translation, and the translation granule size.

Accessing the TTBR0_EL2:

To access the TTBR0_EL2:

MRS <Xt>, TTBR0_EL2 ; Read TTBR0_EL2 into Xt
MSR TTBR0_EL2, <Xt> ; Write Xt to TTBR0_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0010 | 0000 | 000 |

D7.2.94 TTBR0_EL3, Translation Table Base Register 0 (EL3)

The TTBR0_EL3 characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR0_EL3 is a 64-bit register.

Field descriptions

The TTBR0_EL3 bit assignments are:

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of [TCR_EL3.T0SZ](#), the stage of translation, and the translation granule size.

Accessing the TTBR0_EL3:

To access the TTBR0_EL3:

MRS <Xt>, TTBR0_EL3 ; Read TTBR0_EL3 into Xt
MSR TTBR0_EL3, <Xt> ; Write Xt to TTBR0_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0010 | 0000 | 000 |

D7.2.95 TTBR1_EL1, Translation Table Base Register 1 (EL1)

The TTBR1_EL1 characteristics are:

Purpose

Holds the base address of translation table 1, and information about the memory it occupies. This is one of the translation tables for the stage 1 translation of memory accesses at EL0 and EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [HCR_EL2.TRVM](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HCR_EL2.TVM](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.

Configurations

AArch64 System register TTBR1_EL1 is architecturally mapped to AArch32 System register [TTBR1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

TTBR1_EL1 is a 64-bit register.

Field descriptions

The TTBR1_EL1 bit assignments are:

ASID, bits [63:48]

An ASID for the translation table base address. The [TCR_EL1.A1](#) field selects either [TTBR0_EL1.ASID](#) or [TTBR1_EL1.ASID](#).

If the implementation has only 8 bits of ASID, then the upper 8 bits of this field are RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.

- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of `TCR_EL1.TISZ`, the stage of translation, and the translation granule size.

Accessing the TTBR1_EL1:

To access the TTBR1_EL1:

MRS <Xt>, TTBR1_EL1 ; Read TTBR1_EL1 into Xt
MSR TTBR1_EL1, <Xt> ; Write Xt to TTBR1_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 0010 | 0000 | 001 |

D7.2.96 VBAR_EL1, Vector Base Address Register (EL1)

The VBAR_EL1 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VBAR_EL1[31:0] is architecturally mapped to AArch32 System register [VBAR](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR_EL1 is a 64-bit register.

Field descriptions

The VBAR_EL1 bit assignments are:

Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL1.

If tagged addresses are being used, bits [55:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL1 must be the same or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL1:

To access the VBAR_EL1:

MRS <Xt>, VBAR_EL1 ; Read VBAR_EL1 into Xt
MSR VBAR_EL1, <Xt> ; Write Xt to VBAR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1100 | 0000 | 000 |

D7.2.97 VBAR_EL2, Vector Base Address Register (EL2)

The VBAR_EL2 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL2.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VBAR_EL2[31:0] is architecturally mapped to AArch32 System register [HVBAR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR_EL2 is a 64-bit register.

Field descriptions

The VBAR_EL2 bit assignments are:

Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL2.

If tagged addresses are being used, bits [55:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL2 must be 0 or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL2:

To access the VBAR_EL2:

MRS <Xt>, VBAR_EL2 ; Read VBAR_EL2 into Xt
MSR VBAR_EL2, <Xt> ; Write Xt to VBAR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1100 | 0000 | 000 |

D7.2.98 VBAR_EL3, Vector Base Address Register (EL3)

The VBAR_EL3 characteristics are:

Purpose

Holds the vector base address for any exception that is taken to EL3.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VBAR_EL3 is a 64-bit register.

Field descriptions

The VBAR_EL3 bit assignments are:

Bits [63:11]

Vector Base Address. Base address of the exception vectors for exceptions taken to EL3.

If tagged addresses are being used, bits [55:48] of VBAR_EL3 must be 0 or else the use of the vector address will result in a recursive exception.

If tagged addresses are not being used, bits [63:48] of VBAR_EL3 must be 0 or else the use of the vector address will result in a recursive exception.

Bits [10:0]

Reserved, RES0.

Accessing the VBAR_EL3:

To access the VBAR_EL3:

MRS <Xt>, VBAR_EL3 ; Read VBAR_EL3 into Xt
MSR VBAR_EL3, <Xt> ; Write Xt to VBAR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 1100 | 0000 | 000 |

D7.2.99 VMPIDR_EL2, Virtualization Multiprocessor ID Register

The VMPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Multiprocessor ID. This is the value returned by Non-secure EL1 reads of [MPIDR_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VMPIDR_EL2[31:0] is architecturally mapped to AArch32 System register [VMPIDR](#).

If EL2 is not implemented, reads of this register return the value of the [MPIDR_EL1](#), and writes to the register are ignored.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VMPIDR_EL2 is a 64-bit register.

Field descriptions

The VMPIDR_EL2 bit assignments are:

Bits [63:40]

Reserved, RES0.

Aff3, bits [39:32]

Affinity level 3. Highest level affinity field.

Bit [31]

Reserved, RES1.

U, bit [30]

Indicates a Uniprocessor system, as distinct from PE 0 in a multiprocessor system. The possible values of this bit are:

- 0 Processor is part of a multiprocessor system.
- 1 Processor is part of a uniprocessor system.

Bits [29:25]

Reserved, RES0.

MT, bit [24]

Indicates whether the lowest level of affinity consists of logical PEs that are implemented using a multithreading type approach. The possible values of this bit are:

- 0 Performance of PEs at the lowest affinity level is largely independent.
- 1 Performance of PEs at the lowest affinity level is very interdependent.

Aff2, bits [23:16]

Affinity level 2. Second highest level affinity field.

Aff1, bits [15:8]

Affinity level 1. Third highest level affinity field.

Aff0, bits [7:0]

Affinity level 0. Lowest level affinity field.

Accessing the VMPIDR_EL2:

To access the VMPIDR_EL2:

MRS <Xt>, VMPIDR_EL2 ; Read VMPIDR_EL2 into Xt
MSR VMPIDR_EL2, <Xt> ; Write Xt to VMPIDR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0000 | 0000 | 101 |

D7.2.100 VPIDR_EL2, Virtualization Processor ID Register

The VPIDR_EL2 characteristics are:

Purpose

Holds the value of the Virtualization Processor ID. This is the value returned by Non-secure EL1 reads of [MIDR_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VPIDR_EL2 is architecturally mapped to AArch32 System register [VPIDR](#).

If EL2 is not implemented, reads of this register return the value of the [MIDR_EL1](#), and writes to the register are ignored.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VPIDR_EL2 is a 32-bit register.

Field descriptions

The VPIDR_EL2 bit assignments are:

Implementer, bits [31:24]

The Implementer code. This field must hold an implementer code that has been assigned by ARM. Assigned codes include the following:

| Hex representation | ASCII representation | Implementer |
|--------------------|----------------------|--|
| 0x41 | A | ARM Limited |
| 0x42 | B | Broadcom Corporation |
| 0x43 | C | Cavium Inc. |
| 0x44 | D | Digital Equipment Corporation |
| 0x49 | I | Infineon Technologies AG |
| 0x4D | M | Motorola or Freescale Semiconductor Inc. |

| Hex representation | ASCII representation | Implementer |
|--------------------|----------------------|------------------------------------|
| 0x4E | N | NVIDIA Corporation |
| 0x50 | P | Applied Micro Circuits Corporation |
| 0x51 | Q | Qualcomm Inc. |
| 0x56 | V | Marvell International Ltd. |
| 0x69 | i | Intel Corporation |

ARM can assign codes that are not published in this manual. All values not assigned by ARM are reserved and must not be used.

Variant, bits [23:20]

An IMPLEMENTATION DEFINED variant number. Typically, this field is used to distinguish between different product variants, or major revisions of a product.

Architecture, bits [19:16]

The permitted values of this field are:

| | |
|------|--|
| 0001 | ARMv4 |
| 0010 | ARMv4T |
| 0011 | ARMv5 (obsolete) |
| 0100 | ARMv5T |
| 0101 | ARMv5TE |
| 0110 | ARMv5TEJ |
| 0111 | ARMv6 |
| 1111 | Architectural features are individually identified in the ID_* registers, see <i>Identification registers, functional group</i> on page G4-4194. |

All other values are reserved.

PartNum, bits [15:4]

An IMPLEMENTATION DEFINED primary part number for the device.

On processors implemented by ARM, if the top four bits of the primary part number are 0x0 or 0x7, the variant and architecture are encoded differently.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the device.

Accessing the VPIDR_EL2:

To access the VPIDR_EL2:

MRS <Xt>, VPIDR_EL2 ; Read VPIDR_EL2 into Xt
MSR VPIDR_EL2, <Xt> ; Write Xt to VPIDR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0000 | 0000 | 000 |

D7.2.101 VTCR_EL2, Virtualization Translation Control Register

The VTCR_EL2 characteristics are:

Purpose

Controls the translation table walks required for the stage 2 translation of memory accesses from Non-secure EL0 and EL1, and holds cacheability and shareability information for the accesses.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Any of the bits in VTCR_EL2 are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VTCR_EL2 is architecturally mapped to AArch32 System register [VTCR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTCR_EL2 is a 32-bit register.

Field descriptions

The VTCR_EL2 bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:19]

Reserved, RES0.

PS, bits [18:16]

Physical Address Size.

- 000 32 bits, 4GB.
- 001 36 bits, 64GB.
- 010 40 bits, 1TB.
- 011 42 bits, 4TB.
- 100 44 bits, 16TB.

101 48 bits, 256TB.

Other values are reserved.

The reserved values behave in the same way as the 101 encoding, but software must not rely on this property as the behavior of the RESERVED values might change in a future revision of the architecture.

TG0, bits [15:14]

Granule size for the [VTTBR_EL2](#).

| | |
|----|------|
| 00 | 4KB |
| 01 | 64KB |
| 10 | 16KB |

Other values are reserved.

If the value is programmed to either a reserved value, or a size that has not been implemented, then the hardware will treat the field as if it has been programmed to an IMPLEMENTATION DEFINED choice of the sizes that has been implemented for all purposes other than the value read back from this register.

It is IMPLEMENTATION DEFINED whether the value read back is the value programmed or the value that corresponds to the size chosen.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [VTTBR_EL2](#).

| | |
|----|-----------------|
| 00 | Non-shareable |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [VTTBR_EL2](#).

| | |
|----|--|
| 00 | Normal memory, Outer Non-cacheable |
| 01 | Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable |

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [VTTBR_EL2](#).

| | |
|----|--|
| 00 | Normal memory, Inner Non-cacheable |
| 01 | Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable |

SL0, bits [7:6]

Starting level of the [VTTCR_EL2](#) addressed region. The meaning of this field depends on the value of [VTTCR_EL2.TG0](#) (the granule size).

| | |
|----|---|
| 00 | If TG0 is 00 (4KB granule), start at level 2. If TG0 is 10 (16KB granule) or 01 (64KB granule), start at level 3. |
| 01 | If TG0 is 00 (4KB granule), start at level 1. If TG0 is 10 (16KB granule) or 01 (64KB granule), start at level 2. |
| 10 | If TG0 is 00 (4KB granule), start at level 0. If TG0 is 10 (16KB granule) or 01 (64KB granule), start at level 1. |

All other values are reserved. If this field is programmed to a reserved value, or to a value that is not consistent with the programming of T0SZ, then a stage 2 level 0 Translation fault is generated.

T0SZ, bits [5:0]

The size offset of the memory region addressed by [VTTBR_EL2](#). The region size is $2^{(64-T0SZ)}$ bytes. The maximum and minimum possible values for T0SZ depend on the level of translation table and the memory translation granule size, as described in the AArch64 Virtual Memory System Architecture chapter.

If this field is programmed to a value that is not consistent with the programming of SL0 then a stage 2 level 0 Translation fault is generated.

Accessing the VTCR_EL2:

To access the VTCR_EL2:

MRS <Xt>, VTCR_EL2 ; Read VTCR_EL2 into Xt
MSR VTCR_EL2, <Xt> ; Write Xt to VTCR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0010 | 0001 | 010 |

D7.2.102 VTTBR_EL2, Virtualization Translation Table Base Register

The VTTBR_EL2 characteristics are:

Purpose

Holds the base address of the translation table for the stage 2 translation of memory accesses from Non-secure EL0 and EL1.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Any of the fields in this register are permitted to be cached in a TLB.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register VTTBR_EL2 is architecturally mapped to AArch32 System register [VTTBR](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

VTTBR_EL2 is a 64-bit register.

Field descriptions

The VTTBR_EL2 bit assignments are:

Bits [63:56]

Reserved, RES0.

VMID, bits [55:48]

The VMID for the translation table.

BADDR, bits [47:0]

Translation table base address, bits[47:x]. Bits [x-1:0] are RES0, with the additional requirement that if they are not all zero, this is a misaligned translation table base address, with effects that are CONstrained UNPREDICTABLE, and must be on of the following:

- Bits [x-1:0] are treated as if all the bits are zero. The value read back from those bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

The AArch64 Virtual Memory System Architecture chapter describes how x is calculated based on the value of [VTCR_EL2.T0SZ](#), the stage of translation, and the translation granule size.

Accessing the VTTBR_EL2:

To access the VTTBR_EL2:

MRS <Xt>, VTTBR_EL2 ; Read VTTBR_EL2 into Xt
MSR VTTBR_EL2, <Xt> ; Write Xt to VTTBR_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0010 | 0001 | 000 |

D7.3 Debug registers

This section lists the Debug System registers in AArch64 state, in alphabetic order:

- The principal encoding space for debug registers is $0p0==0b10$, $0p1==\{0, 3, 4\}$. *Instructions for accessing debug System registers on page C5-280* summarizes the registers in this encoding space and lists them in order of their encodings.
- In addition, the following registers in the $0p0==0b11$ encoding space are classified as Debug registers:
 - [DLR_EL0](#).
 - [DSPSR_EL0](#).
 - [MDCR_EL2](#).
 - [MDCR_EL3](#).
 - [SDER32_EL3](#).

D7.3.1 DBGAUTHSTATUS_EL1, Debug Authentication Status register

The DBGAUTHSTATUS_EL1 characteristics are:

Purpose

Provides information about the state of the IMPLEMENTATION DEFINED authentication interface for debug.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `MDCR_EL2.TDA==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `MDCR_EL3.TDA==1`, read accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register DBGAUTHSTATUS_EL1 is architecturally mapped to AArch32 System register [DBGAUTHSTATUS](#).

AArch64 System register DBGAUTHSTATUS_EL1 is architecturally mapped to External register [DBGAUTHSTATUS_EL1](#).

Attributes

DBGAUTHSTATUS_EL1 is a 32-bit register.

Field descriptions

The DBGAUTHSTATUS_EL1 bit assignments are:

Bits [31:8]

Reserved, RES0.

SNID, bits [7:6]

Secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. `ExternalSecureNoninvasiveDebugEnabled() == FALSE`.
- 11 Implemented and enabled. `ExternalSecureNoninvasiveDebugEnabled() == TRUE`.

Other values are reserved.

SID, bits [5:4]

Secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Non-secure state.
- 10 Implemented and disabled. ExternalSecureInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalSecureInvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSNID, bits [3:2]

Non-secure non-invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- 10 Implemented and disabled. ExternalNoninvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalNoninvasiveDebugEnabled() == TRUE.

Other values are reserved.

NSID, bits [1:0]

Non-secure invasive debug. Possible values of this field are:

- 00 Not implemented. EL3 is not implemented and the implemented Security state is Secure state.
- 10 Implemented and disabled. ExternalInvasiveDebugEnabled() == FALSE.
- 11 Implemented and enabled. ExternalInvasiveDebugEnabled() == TRUE.

Other values are reserved.

Accessing the DBGAUTHSTATUS_EL1:

To access the DBGAUTHSTATUS_EL1:

MRS <Xt>, DBGAUTHSTATUS_EL1 ; Read DBGAUTHSTATUS_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0111 | 1110 | 110 |

D7.3.2 DBGBCR<n>_EL1, Debug Breakpoint Control Registers, n = 0 - 15

The DBGBCR<n>_EL1 characteristics are:

Purpose

Holds control information for a breakpoint. Forms breakpoint n together with value register [DBGBVR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) and [Software Access debug event on page H3-4903](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.
- If [EDSCR.TDA==1](#), [OSLSR_EL1.OSLK==0](#), and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access Debug event.

Configurations

AArch64 System register DBGBCR<n>_EL1 is architecturally mapped to AArch32 System register [DBGBCR<n>](#).

AArch64 System register DBGBCR<n>_EL1 is architecturally mapped to External register [DBGBCR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGBCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGBCR<n>_EL1 bit assignments are:

Bits [31:24]

Reserved, RES0.

BT, bits [23:20]

Breakpoint Type. Possible values are:

- 0000 Unlinked instruction address match.

| | |
|------|-------------------------------------|
| 0001 | Linked instruction address match. |
| 0010 | Unlinked context ID match. |
| 0011 | Linked context ID match |
| 1000 | Unlinked VMID match. |
| 1001 | Linked VMID match. |
| 1010 | Unlinked VMID and context ID match. |
| 1011 | Linked VMID and context ID match. |

The field breaks down as follows:

- BT[3:1]: Base type.

| | |
|-----|---|
| 000 | Match address. DBGVVR<n>_EL1 is the address of an instruction. |
| 001 | Match context ID. DBGVVR<n>_EL1.ContextID is a context ID. |
| 100 | Match VMID. DBGVVR<n>_EL1.VMID is a VMID. |
| 101 | Match VMID and context ID. DBGVVR<n>_EL1.ContextID is a context ID, and DBGVVR<n>_EL1.VMID is a VMID. |
- BT[0]: Enable linking.

All other values are reserved. Constraints on breakpoint programming mean other values are reserved under some conditions. For more information, including the effect of programming this field to a reserved value, see [Reserved DBGBCR<n>_EL1.BT values on page D2-1652](#).

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked address matching breakpoints, this specifies the index of the Context-matching breakpoint linked to.

For all other breakpoint types this field is ignored and reads of the register return an UNKNOWN value.

This field is ignored when the value of [DBGBCR<n>_EL1.E](#) is 0.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the HMC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information, including the effect of programming the fields to a reserved set of values, see [Reserved DBGBCR<n>_EL1.{SSC, HMC, PMC} values on page D2-1652](#).

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and PMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the SSC, bits [15:14] description.

This field resets to a value that is architecturally UNKNOWN.

Bits [12:9]

Reserved, RES0.

BAS, bits [8:5]

Byte address select. Defines which half-words an address-matching breakpoint matches, regardless of the instruction set and Execution state. In an AArch64-only implementation, this field is reserved, RES1.

The permitted values depend on the breakpoint type.

For Address match breakpoints, the permitted values are:

| BAS | Match instruction at | Constraint for debuggers |
|------|----------------------|-----------------------------------|
| 0011 | DBGBVR<n>_EL1 | Use for T32 instructions. |
| 1100 | DBGBVR<n>_EL1+2 | Use for T32 instructions. |
| 1111 | DBGBVR<n>_EL1 | Use for A64 and A32 instructions. |

All other values are reserved. For more information, see *Reserved DBGBCR<n>_EL1.BAS values on page D2-1653*.

For more information on using the BAS field in address match breakpoints, see *Using the BAS field in Address Match breakpoints on page G2-3949*.

For Context matching breakpoints, this field is RES1 and ignored.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES0.

PMC, bits [2:1]

Privilege mode control. Determines the Exception level or levels at which a Breakpoint debug event for breakpoint n is generated. This field must be interpreted along with the SSC and HMC fields, and there are constraints on the permitted values of the {HMC, SSC, PMC} fields. For more information see the DBGBCR<n>_EL1.SSC description.

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable breakpoint [DBGBVR<n>_EL1](#). Possible values are:

- 0 Breakpoint disabled.
- 1 Breakpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGBCR<n>_EL1:

To access the DBGBCR<n>_EL1:

MRS <Xt>, DBGBCR<n>_EL1 ; Read DBGBCR<n>_EL1 into Xt, where n is in the range 0 to 15
MSR DBGBCR<n>_EL1, <Xt> ; Write Xt to DBGBCR<n>_EL1, where n is in the range 0 to 15

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|--------|-----|
| 10 | 000 | 0000 | n<3:0> | 101 |

D7.3.3 DBGBVR<n>_EL1, Debug Breakpoint Value Registers, n = 0 - 15

The DBGBVR<n>_EL1 characteristics are:

Purpose

Holds a virtual address, or a VMID and/or a context ID, for use in breakpoint matching. Forms breakpoint n together with control register [DBGBCR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) and [Software Access debug event on page H3-4903](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.
- If [EDSCR.TDA==1](#), [OSLSR_EL1.OSLK==0](#), and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access Debug event.

Configurations

AArch64 System register DBGBVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register [DBGBVR<n>](#).

If the breakpoint is context-aware and EL2 is implemented then AArch64 System register DBGBVR<n>_EL1[63:32] is architecturally mapped to AArch32 System register [DBGXVR<n>](#). Otherwise there is no System register access to DBGBVR<n>_EL1[63:32] from AArch32 state.

AArch64 System register DBGBVR<n>_EL1 is architecturally mapped to External register [DBGBVR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

How this register is interpreted depends on the value of [DBGBCR<n>_EL1.BT](#).

- When [DBGBCR<n>_EL1.BT](#) is 0b000x, this register holds a virtual address.
- When [DBGBCR<n>_EL1.BT](#) is 0b001x, this register holds a Context ID.
- When [DBGBCR<n>_EL1.BT](#) is 0b100x, this register holds a VMID.
- When [DBGBCR<n>_EL1.BT](#) is 0b101x, this register holds a VMID and a Context ID.

For other values of [DBGBCR<n>_EL1.BT](#), this register is RES0.

Field descriptions

The DBGBVR<n>_EL1 bit assignments are:

When $DBGBCR<n>_{EL1.BT} = 0b000x$:

RESS, bits [63:49]

Reserved, Sign extended. Software must treat this field as RES0 if bit[48] is 0 or RES0, and as RES1 if bit[48] is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of bit [48], meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.
- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

This field resets to a value that is architecturally UNKNOWN.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

When $DBGBCR<n>_{EL1.BT} = 0b001x$:

Bits [63:32]

Reserved, RES0.

ContextID, bits [31:0]

Context ID value for comparison.

This field resets to a value that is architecturally UNKNOWN.

When $DBGBCR<n>_{EL1.BT} = 0b100x$ and EL2 implemented:

Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

VMID value for comparison.

This field resets to a value that is architecturally UNKNOWN.

Bits [31:0]

Reserved, RES0.

When $DBGBCR<n>_{EL1}.BT=0b101x$ and EL2 implemented:

Bits [63:40]

Reserved, RES0.

VMID, bits [39:32]

VMID value for comparison.

This field resets to a value that is architecturally UNKNOWN.

ContextID, bits [31:0]

Context ID value for comparison.

This field resets to a value that is architecturally UNKNOWN.

Accessing the $DBGBVR<n>_{EL1}$:

To access the $DBGBVR<n>_{EL1}$:

MRS <Xt>, $DBGBVR<n>_{EL1}$; Read $DBGBVR<n>_{EL1}$ into Xt, where n is in the range 0 to 15
MSR $DBGBVR<n>_{EL1}$, <Xt> ; Write Xt to $DBGBVR<n>_{EL1}$, where n is in the range 0 to 15

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|--------|-----|
| 10 | 000 | 0000 | n<3:0> | 100 |

D7.3.4 DBGCLAIMCLR_EL1, Debug Claim Tag Clear register

The DBGCLAIMCLR_EL1 characteristics are:

Purpose

Used by software to read the values of the CLAIM tag bits, and to clear these bits to 0. The architecture does not define any functionality for the CLAIM tag bits.

———— **Note** ————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMSET_EL1](#) register.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register DBGCLAIMCLR_EL1 is architecturally mapped to AArch32 System register [DBGCLAIMCLR](#).

AArch64 System register DBGCLAIMCLR_EL1 is architecturally mapped to External register [DBGCLAIMCLR_EL1](#).

An implementation must include 8 CLAIM tag bits.

This register is in the Cold reset domain. See the CLAIM field description for the effect of a Cold reset on the value returned by this register. This register is not affected by a Warm reset.

Attributes

DBGCLAIMCLR_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMCLR_EL1 bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Read or clear CLAIM tag bits. Reading this field returns the current value of the CLAIM tag bits.

Writing a 1 to one of these bits clears the corresponding CLAIM tag bit to 0. This is an indirect write to the CLAIM tag bits. A single write operation can clear multiple CLAIM tag bits to 0.

Writing 0 to one of these bits has no effect.

A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMCLR_EL1:

To access the DBGCLAIMCLR_EL1:

MRS <Xt>, DBGCLAIMCLR_EL1 ; Read DBGCLAIMCLR_EL1 into Xt
MSR DBGCLAIMCLR_EL1, <Xt> ; Write Xt to DBGCLAIMCLR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0111 | 1001 | 110 |

D7.3.5 DBGCLAIMSET_EL1, Debug Claim Tag Set register

The DBGCLAIMSET_EL1 characteristics are:

Purpose

Used by software to set the CLAIM tag bits to 1.

The architecture does not define any functionality for the CLAIM tag bits.

———— Note —————

CLAIM tags are typically used for communication between the debugger and target software.

Used in conjunction with the [DBGCLAIMCLR_EL1](#) register.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register DBGCLAIMSET_EL1 is architecturally mapped to AArch32 System register [DBGCLAIMSET](#).

AArch64 System register DBGCLAIMSET_EL1 is architecturally mapped to External register [DBGCLAIMSET_EL1](#).

An implementation must include 8 CLAIM tag bits.

Attributes

DBGCLAIMSET_EL1 is a 32-bit register.

Field descriptions

The DBGCLAIMSET_EL1 bit assignments are:

Bits [31:8]

Reserved, RAZ/SBZ. Software can rely on these bits reading as zero, and must use a should-be-zero policy on writes. Implementations must ignore writes.

CLAIM, bits [7:0]

Set CLAIM tag bits. RAO.

Writing a 1 to one of these bits sets the corresponding CLAIM tag bit to 1. This is an indirect write to the CLAIM tag bits. A single write operation can set multiple CLAIM tag bits to 1.

Writing 0 to one of these bits has no effect.
A cold reset clears the CLAIM tag bits to 0.

Accessing the DBGCLAIMSET_EL1:

To access the DBGCLAIMSET_EL1:

MRS <Xt>, DBGCLAIMSET_EL1 ; Read DBGCLAIMSET_EL1 into Xt
MSR DBGCLAIMSET_EL1, <Xt> ; Write Xt to DBGCLAIMSET_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0111 | 1000 | 110 |

D7.3.6 DBGDTR_EL0, Debug Data Transfer Register, half-duplex

The DBGDTR_EL0 characteristics are:

Purpose

Transfers 64 bits of data between the PE and an external debugger. Can transfer both ways using only a single register.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules, in Non-debug state:

- If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If `MDCR_EL3.TDA==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If `MDSCR_EL1.TDCC==1`, accesses to this register from EL0 are trapped to EL1.

———— **Note** —————

Read and write accesses to this register are not trapped in Debug state.

Configurations

There are no configuration notes.

Attributes

DBGDTR_EL0 is a 64-bit register.

Field descriptions

The DBGDTR_EL0 bit assignments are:

HighWord, bits [63:32]

Writes to this register set `DTRRX` to the value in this field and do not change `RXfull`.

Reads from this register return the value of `DTRTX` and do not change `TXfull`.

LowWord, bits [31:0]

Writes to this register set `DTRTX` to the value in this field and set `TXfull` to 1.

Reads from this register return the value of `DTRRX` and clear `RXfull` to 0.

Accessing the DBGDTR_EL0:

To access the DBGDTR_EL0:

MRS <Xt>, DBGDTR_EL0 ; Read DBGDTR_EL0 into Xt
MSR DBGDTR_EL0, <Xt> ; Write Xt to DBGDTR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 011 | 0000 | 0100 | 000 |

D7.3.7 DBGDTRRX_EL0, Debug Data Transfer Register, Receive

The DBGDTRRX_EL0 characteristics are:

Purpose

Transfers data from an external debugger to the PE. For example, it is used by a debugger transferring commands and data to a debug target. It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules, in Non-debug state:

- If `MDCR_EL2.TDA==1`, Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- If `MDCR_EL3.TDA==1`, read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If `MDSCR_EL1.TDCC==1`, read accesses to this register from EL0 are trapped to EL1.

———— **Note** —————

Read accesses to this register are not trapped in Debug state.

Configurations

AArch64 System register DBGDTRRX_EL0 is architecturally mapped to AArch32 System register `DBGDTRRXint`.

AArch64 System register DBGDTRRX_EL0 is architecturally mapped to External register `DBGDTRRX_EL0`.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGDTRRX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRRX_EL0 bit assignments are:

Bits [31:0]

Update DTRRX.

If `RXfull` is set to 1, then reads of this register return the last value written to DTRRX and clear `RXfull` to 0.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRRX_EL0:

To access the DBGDTRRX_EL0:

MRS <Xt>, DBGDTRRX_EL0 ; Read DBGDTRRX_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 011 | 0000 | 0101 | 000 |

D7.3.8 DBGDTRTX_EL0, Debug Data Transfer Register, Transmit

The DBGDTRTX_EL0 characteristics are:

Purpose

Transfers data from the PE to an external debugger. For example, it is used by a debug target to transfer data to the debugger. It is a component of the Debug Communication Channel.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-WO | WO | WO | WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules, in Non-debug state:

- If `MDCR_EL2.TDA==1`, Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- If `MDCR_EL3.TDA==1`, write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If `MDSCR_EL1.TDCC==1`, write accesses to this register from EL0 are trapped to EL1.

———— **Note** —————

Write accesses to this register are not trapped in Debug state.

Configurations

AArch64 System register DBGDTRTX_EL0 is architecturally mapped to AArch32 System register [DBGDTRTXint](#).

AArch64 System register DBGDTRTX_EL0 is architecturally mapped to External register [DBGDTRTX_EL0](#).

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGDTRTX_EL0 is a 32-bit register.

Field descriptions

The DBGDTRTX_EL0 bit assignments are:

Bits [31:0]

Return DTRTX.

If TXfull is set to 0, then writes of this register update the value in DTRTX and set TXfull to 1.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

This field resets to a value that is architecturally UNKNOWN.

Accessing the DBGDTRTX_EL0:

To access the DBGDTRTX_EL0:

MSR DBGDTRTX_EL0, <Xt> ; Write Xt to DBGDTRTX_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 011 | 0000 | 0101 | 000 |

D7.3.9 DBGPRCR_EL1, Debug Power Control Register

The DBGPRCR_EL1 characteristics are:

Purpose

Controls behavior of the PE on powerdown request.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548*. Subject to the prioritization rules:

- If `MDCR_EL2.TDOSA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `MDCR_EL3.TDOSA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register DBGPRCR_EL1 is architecturally mapped to AArch32 System register `DBGPRCR`.

Bit [0] of this register is mapped to `EDPRCR.CORENPDRQ`, bit [0] of the external view of this register.

The other bits in these registers are not mapped to each other.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGPRCR_EL1 is a 32-bit register.

Field descriptions

The DBGPRCR_EL1 bit assignments are:

Bits [31:1]

Reserved, RES0.

CORENPDRQ, bit [0]

Core no powerdown request. Requests emulation of powerdown. Possible values of this bit are:

- 0 If the system responds to a powerdown request, it powers down Core power domain.
- 1 If the system responds to a powerdown request, it does not powerdown the Core power domain, but instead emulates a powerdown of that domain.

Writes to this bit are permitted regardless of the state of the IMPLEMENTATION DEFINED authentication interface. This means that a debugger can request Core no powerdown regardless of whether invasive debug is permitted.

It is IMPLEMENTATION DEFINED whether this bit is reset to the value of [EDPRCR.COREPURQ](#) on exit from an IMPLEMENTATION DEFINED software-visible retention state.

Accessing the DBGPRCR_EL1:

To access the DBGPRCR_EL1:

MRS <Xt>, DBGPRCR_EL1 ; Read DBGPRCR_EL1 into Xt
MSR DBGPRCR_EL1, <Xt> ; Write Xt to DBGPRCR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0001 | 0100 | 100 |

D7.3.10 DBGVCR32_EL2, Debug Vector Catch Register

The DBGVCR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register [DBGVCR](#) from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL3.TDA](#)==1, accesses to this register from EL2 are trapped to EL3.

Configurations

AArch64 System register [DBGVCR32_EL2](#) is architecturally mapped to AArch32 System register [DBGVCR](#).

If EL1 does not support AArch32, this register is UNDEFINED.

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

[DBGVCR32_EL2](#) is a 32-bit register.

Field descriptions

The [DBGVCR32_EL2](#) bit assignments are:

When EL3 implemented and using AArch64:

NSF, bit [31]

FIQ vector catch enable in Non-secure state.

The exception vector offset is $0x1C$.

This field resets to a value that is architecturally UNKNOWN.

NSI, bit [30]

IRQ vector catch enable in Non-secure state.

The exception vector offset is 0x18.

This field resets to a value that is architecturally UNKNOWN.

Bit [29]

Reserved, RES0.

NSD, bit [28]

Data Abort vector catch enable in Non-secure state.

The exception vector offset is 0x10.

This field resets to a value that is architecturally UNKNOWN.

NSP, bit [27]

Prefetch Abort vector catch enable in Non-secure state.

The exception vector offset is 0x0C.

This field resets to a value that is architecturally UNKNOWN.

NSS, bit [26]

Supervisor Call (SVC) vector catch enable in Non-secure state.

The exception vector offset is 0x08.

This field resets to a value that is architecturally UNKNOWN.

NSU, bit [25]

Undefined Instruction vector catch enable in Non-secure state.

The exception vector offset is 0x04.

This field resets to a value that is architecturally UNKNOWN.

Bits [24:8]

Reserved, RES0.

SF, bit [7]

FIQ vector catch enable in Secure state.

The exception vector offset is 0x1C.

This field resets to a value that is architecturally UNKNOWN.

SI, bit [6]

IRQ vector catch enable in Secure state.

The exception vector offset is 0x18.

This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

SD, bit [4]

Data Abort vector catch enable in Secure state.

The exception vector offset is 0x10.

This field resets to a value that is architecturally UNKNOWN.

SP, bit [3]

Prefetch Abort vector catch enable in Secure state.

The exception vector offset is $0x0C$.
This field resets to a value that is architecturally UNKNOWN.

SS, bit [2]

Supervisor Call (SVC) vector catch enable in Secure state.
The exception vector offset is $0x08$.
This field resets to a value that is architecturally UNKNOWN.

SU, bit [1]

Undefined Instruction vector catch enable in Secure state.
The exception vector offset is $0x04$.
This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

When EL3 not implemented:

Bits [31:8]

Reserved, RES0.

F, bit [7]

FIQ vector catch enable.
The exception vector offset is $0x1C$.
This field resets to a value that is architecturally UNKNOWN.

I, bit [6]

IRQ vector catch enable.
The exception vector offset is $0x18$.
This field resets to a value that is architecturally UNKNOWN.

Bit [5]

Reserved, RES0.

D, bit [4]

Data Abort vector catch enable.
The exception vector offset is $0x10$.
This field resets to a value that is architecturally UNKNOWN.

P, bit [3]

Prefetch Abort vector catch enable.
The exception vector offset is $0x0C$.
This field resets to a value that is architecturally UNKNOWN.

S, bit [2]

Supervisor Call (SVC) vector catch enable.

The exception vector offset is 0x08.

This field resets to a value that is architecturally UNKNOWN.

U, bit [1]

Undefined Instruction vector catch enable.

The exception vector offset is 0x04.

This field resets to a value that is architecturally UNKNOWN.

Bit [0]

Reserved, RES0.

Accessing the DBGVCR32_EL2:

To access the DBGVCR32_EL2:

MRS <Xt>, DBGVCR32_EL2 ; Read DBGVCR32_EL2 into Xt

MSR DBGVCR32_EL2, <Xt> ; Write Xt to DBGVCR32_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 100 | 0000 | 0111 | 000 |

D7.3.11 DBGWCR<n>_EL1, Debug Watchpoint Control Registers, n = 0 - 15

The DBGWCR<n>_EL1 characteristics are:

Purpose

Holds control information for a watchpoint. Forms watchpoint n together with value register [DBGWVR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) and [Software Access debug event on page H3-4903](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.
- If [EDSCR.TDA==1](#), [OSLSR_EL1.OSLK==0](#), and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access Debug event.

Configurations

AArch64 System register DBGWCR<n>_EL1 is architecturally mapped to AArch32 System register [DBGWCR<n>](#).

AArch64 System register DBGWCR<n>_EL1 is architecturally mapped to External register [DBGWCR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGWCR<n>_EL1 is a 32-bit register.

Field descriptions

The DBGWCR<n>_EL1 bit assignments are:

Bits [31:29]

Reserved, RES0.

MASK, bits [28:24]

Address mask. Only objects up to 2GB can be watched using a single mask.

00000 No mask.

00001 Reserved.

00010 Reserved.

If programmed with a reserved value, a watchpoint must behave as if either:

- MASK has been programmed with a defined value, which might be 0 (no mask), other than for a direct read of DBGWCRn_EL1.
- The watchpoint is disabled.

Software must not rely on this property because the behavior of reserved values might change in a future revision of the architecture.

Other values mask the corresponding number of address bits, from 0b00011 masking 3 address bits (0x00000007 mask for address) to 0b11111 masking 31 address bits (0x7FFFFFFF mask for address).

This field resets to a value that is architecturally UNKNOWN.

Bits [23:21]

Reserved, RES0.

WT, bit [20]

Watchpoint type. Possible values are:

0 Unlinked data address match.

1 Linked data address match.

This field resets to a value that is architecturally UNKNOWN.

LBN, bits [19:16]

Linked breakpoint number. For Linked data address watchpoints, this specifies the index of the Context-matching breakpoint linked to.

This field resets to a value that is architecturally UNKNOWN.

SSC, bits [15:14]

Security state control. Determines the Security states under which a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the HMC and PAC fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1660](#).

This field resets to a value that is architecturally UNKNOWN.

HMC, bit [13]

Higher mode control. Determines the debug perspective for deciding when a Watchpoint debug event for watchpoint n is generated. This field must be interpreted along with the SSC and PAC fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1660](#).

This field resets to a value that is architecturally UNKNOWN.

BAS, bits [12:5]

Byte address select. Each bit of this field selects whether a byte from within the word or double-word addressed by DBGWVR<n>_EL1 is being watched.

| BAS | Description |
|------------|-------------------------------|
| xxxxxx1 | Match byte at DBGWVR<n>_EL1 |
| xxxxxx1x | Match byte at DBGWVR<n>_EL1+1 |
| xxxxxx1xx | Match byte at DBGWVR<n>_EL1+2 |
| xxxxxx1xxx | Match byte at DBGWVR<n>_EL1+3 |

In cases where `DBGWVR<n>_EL1` addresses a double-word:

| BAS | Description, if <code>DBGWVR<n>_EL1[2] == 0</code> |
|----------|--|
| xxx1xxxx | Match byte at <code>DBGWVR<n>_EL1+4</code> |
| xx1xxxxx | Match byte at <code>DBGWVR<n>_EL1+5</code> |
| x1xxxxxx | Match byte at <code>DBGWVR<n>_EL1+6</code> |
| 1xxxxxxx | Match byte at <code>DBGWVR<n>_EL1+7</code> |

If `DBGWVR<n>_EL1[2] == 1`, only `BAS[3:0]` are used and `BAS[7:4]` are ignored. ARM deprecates setting `DBGWVR<n>_EL1[2] == 1`.

The valid values for `BAS` are non-zero binary numbers all of whose set bits are contiguous. All other values are reserved and must not be used by software. See [Reserved `DBGWCR<n>_EL1.BAS` values on page D2-1668](#).

This field resets to a value that is architecturally UNKNOWN.

LSC, bits [4:3]

Load/store control. This field enables watchpoint matching on the type of access being made. Possible values of this field are:

- 01 Match instructions that load from a watchpointed address.
- 10 Match instructions that store to a watchpointed address.
- 11 Match instructions that load from or store to a watchpointed address.

All other values are reserved, but must behave as if the watchpoint is disabled. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field resets to a value that is architecturally UNKNOWN.

PAC, bits [2:1]

Privilege of access control. Determines the Exception level or levels at which a Watchpoint debug event for watchpoint `n` is generated. This field must be interpreted along with the `SSC` and `HMC` fields, see [Execution conditions for which a watchpoint generates Watchpoint exceptions on page D2-1660](#).

This field resets to a value that is architecturally UNKNOWN.

E, bit [0]

Enable watchpoint `n`. Possible values are:

- 0 Watchpoint disabled.
- 1 Watchpoint enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the `DBGWCR<n>_EL1`:

To access the `DBGWCR<n>_EL1`:

`MRS <Xt>, DBGWCR<n>_EL1` ; Read `DBGWCR<n>_EL1` into `Xt`, where `n` is in the range 0 to 15
`MSR DBGWCR<n>_EL1, <Xt>` ; Write `Xt` to `DBGWCR<n>_EL1`, where `n` is in the range 0 to 15

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|---------------------------|-----|
| 10 | 000 | 0000 | <code>n<3:0></code> | 111 |

D7.3.12 DBGWVR<n>_EL1, Debug Watchpoint Value Registers, n = 0 - 15

The DBGWVR<n>_EL1 characteristics are:

Purpose

Holds a data address value for use in watchpoint matching. Forms watchpoint n together with control register [DBGWCR<n>_EL1](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) and [Software Access debug event on page H3-4903](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.
- If [EDSCR.TDA==1](#), [OSLSR_EL1.OSLK==0](#), and halting is allowed, EL1, EL2, and EL3 accesses to this register generate a Software Access Debug event.

Configurations

AArch64 System register DBGWVR<n>_EL1[31:0] is architecturally mapped to AArch32 System register [DBGWVR<n>](#).

AArch64 System register DBGWVR<n>_EL1 is architecturally mapped to External register [DBGWVR<n>_EL1](#).

If breakpoint n is not implemented then this register is unallocated.

This register is in the Cold reset domain. On a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

DBGWVR<n>_EL1 is a 64-bit register.

Field descriptions

The DBGWVR<n>_EL1 bit assignments are:

RESS, bits [63:49]

Reserved, Sign extended. Hardware and software must treat this field as RES0 if bit[48] is 0 or RES0, and as RES1 if bit[48] is 1.

Hardware always ignores the value of these bits and it is IMPLEMENTATION DEFINED whether:

- The bits are hardwired to a copy of bit [48], meaning writes to these bits are ignored, and reads to the bits always return the hardwired value.

- The value in those bits can be written, and reads will return the last value written. The value held in those bits is ignored by hardware.

This field resets to a value that is architecturally UNKNOWN.

VA, bits [48:2]

Bits[48:2] of the address value for comparison.

ARM deprecates setting `DBGWVR<n>_EL1[2] == 1`.

This field resets to a value that is architecturally UNKNOWN.

Bits [1:0]

Reserved, RES0.

Accessing the `DBGWVR<n>_EL1`:

To access the `DBGWVR<n>_EL1`:

MRS `<Xt>`, `DBGWVR<n>_EL1` ; Read `DBGWVR<n>_EL1` into `Xt`, where `n` is in the range 0 to 15
MSR `DBGWVR<n>_EL1`, `<Xt>` ; Write `Xt` to `DBGWVR<n>_EL1`, where `n` is in the range 0 to 15

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|--------|-----|
| 10 | 000 | 0000 | n<3:0> | 110 |

D7.3.13 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RW | RW | RW | RW | RW | RW |

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DLR_EL0[31:0] is architecturally mapped to AArch32 System register [DLR](#).

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

The DLR_EL0 bit assignments are:

Bits [63:0]

Restart address.

Accessing the DLR_EL0:

To access the DLR_EL0:

MRS <Xt>, DLR_EL0 ; Read DLR_EL0 into Xt
MSR DLR_EL0, <Xt> ; Write Xt to DLR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 0100 | 0101 | 001 |

D7.3.14 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved process state on entry to Debug state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RW | RW | RW | RW | RW | RW |

Access to this register is from Debug state only. During normal execution this register is unallocated.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register DSPSR_EL0 is architecturally mapped to AArch32 System register [DSPSR](#).

Attributes

DSPSR_EL0 is a 32-bit register.

Field descriptions

The DSPSR_EL0 bit assignments are:

When exiting Debug state to AArch32:

N, bit [31]

Copied to [CPSR.N](#) on exiting Debug state.

Z, bit [30]

Copied to [CPSR.Z](#) on exiting Debug state.

C, bit [29]

Copied to [CPSR.C](#) on exiting Debug state.

V, bit [28]

Copied to [CPSR.V](#) on exiting Debug state.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:22]

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.

1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the Debug state entry was taken from. Possible values of this bit are:

- 0 Taken from A32 state.
- 1 Taken from T32 state.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

- 1 Exception taken from AArch32.

M[3:0], bits [3:0]

AArch32 mode that Debug state was entered from. The possible values are:

| M[3:0] | Mode |
|--------|------------|
| 0b0000 | User |
| 0b0001 | FIQ |
| 0b0010 | IRQ |
| 0b0011 | Supervisor |
| 0b0110 | Monitor |
| 0b0111 | Abort |
| 0b1010 | Hyp |
| 0b1011 | Undefined |
| 0b1111 | System |

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5492.

When entering Debug state from AArch64 and exiting Debug state to AArch64:

N, bit [31]

Set to the value of the N condition flag on entering Debug state, and copied to the N condition flag on exiting Debug state.

Z, bit [30]

Set to the value of the Z condition flag on entering Debug state, and copied to the Z condition flag on exiting Debug state.

C, bit [29]

Set to the value of the C condition flag on entering Debug state, and copied to the C condition flag on exiting Debug state.

V, bit [28]

Set to the value of the V condition flag on entering Debug state, and copied to the V condition flag on exiting Debug state.

Bits [27:22]

Reserved, RES0.

SS, bit [21]

Software step. Shows the value of PSTATE.SS immediately before Debug state was entered.

IL, bit [20]

Illegal Execution state bit. Shows the value of PSTATE.IL immediately before Debug state was entered.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

- 0 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are not masked.
- 1 Watchpoint, Breakpoint, and Software Step exceptions targeted at the current Exception level are masked.

When the target Exception level of the debug exception is higher than the current Exception level, the exception is not masked by this bit.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that Debug state was entered from. Possible values of this bit are:

0 Exception taken from AArch64.

M[3:0], bits [3:0]

AArch64 mode that Debug state was entered from. The possible values are:

| M[3:0] | Mode |
|--------|------|
| 0b0000 | EL0t |
| 0b0100 | EL1t |
| 0b0101 | EL1h |
| 0b1000 | EL2t |
| 0b1001 | EL2h |
| 0b1100 | EL3t |
| 0b1101 | EL3h |

Other values are reserved, and returning to an Exception level that is using AArch64 with a reserved value in this field is treated as an illegal exception return.

The bits in this field are interpreted as follows:

- M[3:2] holds the Exception Level.
- M[1] is unused and is RES0 for all non-reserved values.
- M[0] is used to select the SP:
 - 0 means the SP is always SP0.
 - 1 means the exception SP is determined by the EL.

Accessing the DSPSR_EL0:

To access the DSPSR_EL0:

MRS <Xt>, DSPSR_EL0 ; Read DSPSR_EL0 into Xt
MSR DSPSR_EL0, <Xt> ; Write Xt to DSPSR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 0100 | 0101 | 000 |

D7.3.15 MDCCINT_EL1, Monitor DCC Interrupt Enable Register

The MDCCINT_EL1 characteristics are:

Purpose

Enables interrupt requests to be signaled based on the DCC status flags.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `MDCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `MDCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register MDCCINT_EL1 is architecturally mapped to AArch32 System register [DBGDCCINT](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCCINT_EL1 is a 32-bit register.

Field descriptions

The MDCCINT_EL1 bit assignments are:

Bit [31]

Reserved, RES0.

RX, bit [30]

DCC interrupt request enable control for DTRRX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0 No interrupt request generated by DTRRX.
- 1 Interrupt request will be generated on `RXfull == 1`.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

TX, bit [29]

DCC interrupt request enable control for DTRTX. Enables a common COMMIRQ interrupt request to be signaled based on the DCC status flags.

- 0 No interrupt request generated by DTRTX.
- 1 Interrupt request will be generated on TXfull == 0.

If legacy COMMRX and COMMTX signals are implemented, then these are not affected by the value of this bit.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [28:0]

Reserved, RES0.

Accessing the MDCCINT_EL1:

To access the MDCCINT_EL1:

MRS <Xt>, MDCCINT_EL1 ; Read MDCCINT_EL1 into Xt
MSR MDCCINT_EL1, <Xt> ; Write Xt to MDCCINT_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0000 | 0010 | 000 |

D7.3.16 MDCCSR_EL0, Monitor DCC Status Register

The MDCCSR_EL0 characteristics are:

Purpose

Main control register for the debug implementation, containing flow-control flags for the DCC. This is an internal, read-only view.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [MDSR_EL1.TDCC==1](#), read accesses to this register from EL0 are trapped to EL1.

Attributes

MDCCSR_EL0 is a 32-bit register.

Field descriptions

The MDCCSR_EL0 bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

DTRRX full. Read-only view of the equivalent bit in the [EDSCR](#).

TXfull, bit [29]

DTRTX full. Read-only view of the equivalent bit in the [EDSCR](#).

Bits [28:19]

Reserved, RES0.

Bits [18:15]

Reserved. Hardware must implement this field as RAZ. Software must not rely on the register reading as zero.

Bits [14:13]

Reserved, RES0.

Bit [12]

Reserved. Hardware must implement this field as RAZ. Software must not rely on the register reading as zero.

Bits [11:6]

Reserved, RES0.

Bits [5:2]

Reserved. Hardware must implement this field as RAZ. Software must not rely on the register reading as zero.

Bits [1:0]

Reserved, RES0.

Accessing the MDCCSR_ELO:

To access the MDCCSR_ELO:

MRS <Xt>, MDCCSR_ELO ; Read MDCCSR_ELO into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 011 | 0000 | 0001 | 000 |

D7.3.17 MDCR_EL2, Monitor Debug Configuration Register (EL2)

The MDCR_EL2 characteristics are:

Purpose

Provides EL2 configuration options for self-hosted debug and the Performance Monitors Extension.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `MDCR_EL3.TDA==1`, accesses to this register from EL2 are trapped to EL3.

Configurations

AArch64 System register MDCR_EL2 is architecturally mapped to AArch32 System register [HDCR](#).

If EL2 is not implemented, this register is RES0 from EL3.

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCR_EL2 is a 32-bit register.

Field descriptions

The MDCR_EL2 bit assignments are:

Bits [31:12]

Reserved, RES0.

TDRA, bit [11]

Trap Debug ROM Address register access. Traps Non-secure System register accesses to the Debug ROM registers to EL2. This trap is from:

- Non-secure EL0 using AArch32.
 - Non-secure EL1, regardless of which Execution state it is using.
- 0 Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are not trapped to EL2.
- 1 Non-secure EL0 and EL1 System register accesses to the Debug ROM registers are trapped to EL2.

The registers for which accesses are trapped are as follows:

AArch64: [MDRAR_EL1](#).

AArch32: [DBGDRAR](#), [DBGDSAR](#).

If [MDCR_EL2.TDE](#) == 1 or [HCR_EL2.TGE](#) == 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to a value that is architecturally UNKNOWN.

TDOSA, bit [10]

Trap debug OS-related register access. Traps Non-secure EL1 System register accesses to the powerdown debug registers to EL2, from both Execution states:

- 0 Non-secure EL1 System register accesses to the powerdown debug registers are not trapped to EL2.
- 1 Non-secure EL1 System register accesses to the powerdown debug registers are trapped to EL2.

The registers for which accesses are trapped are as follows:

AArch64: [OSLAR_EL1](#), [OSLSR_EL1](#), [OSDLR_EL1](#), and the [DBGPRCR_EL1](#).

AArch32: [DBGOSLSR](#), [DBGOSLAR](#), [DBGOSDLR](#), and the [DBGPRCR](#).

AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

———— Note —————

These registers are not accessible at EL0.

If [MDCR_EL2.TDE](#) == 1 or [HCR_EL2.TGE](#) == 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to a value that is architecturally UNKNOWN.

TDA, bit [9]

Trap Debug Access. Traps Non-secure EL0 and EL1 System register accesses to those debug System registers that are not trapped by either of the following:

- [MDCR_EL2.TDRA](#).
 - [MDCR_EL2.TDOSA](#).
- 0 Has no effect on System register accesses to the debug registers.
- 1 Non-secure EL0 or EL1 System register accesses to the debug registers, other than the registers trapped by [MDCR_EL2.TDRA](#) and [MDCR_EL2.TDOSA](#), are trapped to EL2, from both Execution states.

Traps of AArch32 accesses to [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

Traps of AArch64 accesses to [DBGDTR_EL0](#), [DBGDTRRX_EL0](#), and [DBGDTRTX_EL0](#) are ignored in Debug state.

If [MDCR_EL2.TDE](#) == 1 or [HCR_EL2.TGE](#) == 1, behavior is as if this bit is 1 other than for the purpose of a direct read.

This field resets to a value that is architecturally UNKNOWN.

TDE, bit [8]

Trap Debug exceptions. The possible values of this field are:

- 0 This control has no effect on the routing of debug exceptions, and has no effect on Non-secure accesses to debug registers.
- 1 In Non-secure state:
 - Debug exceptions generated at EL1 or EL0 are routed to EL2.
 - The MDCR_EL2.{TDRA, TDOSA, TDA} fields are treated as being 1 for all purposes other than returning the result of a direct read of the register.

When [HCR_EL2.TGE](#) == 1, the PE behaves as if the value of this field is 1 for all purposes other than returning the value of a direct read of the register.

This field resets to a value that is architecturally UNKNOWN.

HPME, bit [7]

Hypervisor Performance Monitors Enable. The possible values of this bit are:

- 0 EL2 Performance Monitors disabled.
- 1 EL2 Performance Monitors enabled.

When the value of this bit is 1, the Performance Monitors counters that are reserved for use from EL2 or Secure state are enabled. For more information see the description of the HPMN field.

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

TPM, bit [6]

Trap Performance Monitors accesses. Traps Non-secure EL0 and EL1 accesses to all Performance Monitors registers to EL2, from both Execution states:

- 0 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are not trapped to EL2.
- 1 Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to EL2.

———— **Note** —————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

TPMCR, bit [5]

Trap [PMCR_EL0](#) or [PMCR](#) accesses. Traps Non-secure EL0 and EL1 accesses to the [PMCR_EL0](#) or [PMCR](#) to EL2.

- 0 Non-secure EL0 and EL1 accesses to the [PMCR_EL0](#) or [PMCR](#) are not trapped to EL2.
- 1 Non-secure EL0 and EL1 accesses to the [PMCR_EL0](#) or [PMCR](#) are trapped to EL2.

———— **Note** —————

EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

HPMN, bits [4:0]

Defines the number of Performance Monitors counters that are accessible from Non-secure EL0 and EL1 modes.

If the Performance Monitors Extension is not implemented, this field is RES0.

In Non-secure state, HPMN divides the Performance Monitors counters as follows. For counter n in Non-secure state:

- If n is in the range $0 \leq n < \text{HPMN}$, the counter is accessible from EL1 and EL2, and from EL0 if permitted by `PMUSERENR_ELO`. `PMCR_ELO.E` enables the operation of counters in this range.
- If n is in the range $\text{HPMN} \leq n < \text{PMCR_ELO.N}$, the counter is accessible only from EL2 and from Secure state. `MDCR_EL2.HPME` enables the operation of counters in this range.

If this field is set to 0, or to a value larger than `PMCR_ELO.N`, then the following CONSTRAINED UNPREDICTABLE behavior applies:

- The value returned by a direct read of `MDCR_EL2.HPMN` is UNKNOWN.
- Either:
 - An UNKNOWN number of counters are reserved for EL2 use. That is, the PE behaves as if `MDCR_EL2.HPMN` is set to an UNKNOWN non-zero value less than `PMCR_ELO.N`.
 - All counters are reserved for EL2 use, meaning no counters are accessible from Non-secure EL1 and Non-secure EL0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to the value of `PMCR_ELO.N`.

Accessing the MDCR_EL2:

To access the MDCR_EL2:

```
MRS <Xt>, MDCR_EL2 ; Read MDCR_EL2 into Xt
MSR MDCR_EL2, <Xt> ; Write Xt to MDCR_EL2
```

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 0001 | 0001 | 001 |

D7.3.18 MDCR_EL3, Monitor Debug Configuration Register (EL3)

The MDCR_EL3 characteristics are:

Purpose

Provides EL3 configuration options for self-hosted debug and the Performance Monitors Extension.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register MDCR_EL3 can be mapped to AArch32 System register [SDCR](#), but this is not architecturally mandated.

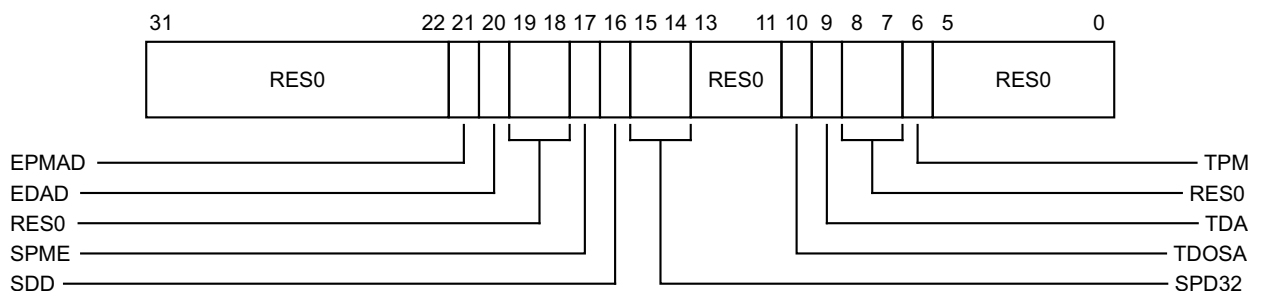

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDCR_EL3 is a 32-bit register.

Field descriptions

The MDCR_EL3 bit assignments are:

Bits [31:22]

Reserved, RES0.

EPMAD, bit [21]

External debug interface Performance Monitors registers disable. This disables access to these registers by an external debugger:

- 0 Access to Performance Monitors registers from external debugger is permitted.
- 1 Access to Performance Monitors registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

If the Performance Monitors Extension is not implemented or does not support external debug interface accesses this bit is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

EDAD, bit [20]

External debug interface breakpoint and watchpoint register access disable. This disables access to these registers by an external debugger:

- 0 Access to breakpoint and watchpoint registers from external debugger is permitted.
- 1 Access to breakpoint and watchpoint registers from external debugger is disabled, unless overridden by the IMPLEMENTATION DEFINED authentication interface.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [19:18]

Reserved, RES0.

SPME, bit [17]

Secure Performance Monitors enable. This allows event counting in Secure state:

- 0 Event counting prohibited in Secure state, unless overridden by the IMPLEMENTATION DEFINED authentication interface.
- 1 Event counting allowed in Secure state.

If the Performance Monitors Extension is not implemented, this field is RES0.

When this register has an architecturally-defined reset value, this field resets to 0.

SDD, bit [16]

AArch64 Secure self-hosted invasive debug disable. Disables Software debug exceptions in Secure state, other than Breakpoint Instruction exceptions.

- 0 Debug exceptions from Secure EL0 are enabled, and debug exceptions from Secure EL1 are enabled if the value of `MDSCR_EL1.KDE` is 1 and the value of `PSTATE.D` is 0.
- 1 Debug exceptions, other than Breakpoint Instruction exceptions, are disabled from all Exception levels in Secure state.

The SDD bit is ignored unless both of the following are true:

- The PE is in Secure state.
- Secure EL1 is using AArch64.

This field resets to a value that is architecturally UNKNOWN.

SPD32, bits [15:14]

AArch32 Secure self-hosted privileged invasive debug control. Enables or disables debug exceptions from Secure EL1 using AArch32, other than Breakpoint Instruction exceptions. Valid values for this field are:

- 00 Legacy mode. Debug exceptions from Secure EL1 are enabled by the IMPLEMENTATION DEFINED authentication interface.
- 10 Secure privileged debug disabled. Debug exceptions from Secure EL1 are disabled.
- 11 Secure privileged debug enabled. Debug exceptions from Secure EL1 are enabled.

Other values are reserved, and have the CONstrained UNPREDICTABLE behavior that they must have the same behavior as 0b00. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

This field has no effect on Breakpoint Instruction exceptions. These are always enabled.

This field is:

- Ignored if either the PE is in Non-secure state or Secure EL1 is using AArch64.
- RES0 if the implementation does not support EL1 using AArch32.

If Secure EL1 is using AArch32 then:

- If debug exceptions from Secure EL1 are enabled, then debug exceptions from Secure EL0 are also enabled.
- Otherwise, debug exceptions from Secure EL0 are enabled only if the value of [SDER32_EL3.SUIDEN](#) is 1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [13:11]

Reserved, RES0.

TDOSA, bit [10]

Trap debug OS-related register access. Traps EL2 and EL1 System register accesses to the powerdown debug registers to EL3:

- | | |
|---|---|
| 0 | EL2 and EL1 System register accesses to the powerdown debug registers are not trapped to EL3. |
| 1 | EL2 and EL1 System register accesses to the powerdown debug registers are trapped to EL3. |

The registers for which accesses are trapped are as follows:

AArch64: [OSLAR_EL1](#), [OSLSR_EL1](#), [OSDLR_EL1](#), [DBGPRCR_EL1](#).

AArch32: [DBGOSLAR](#), [DBGOSLSR](#), [DBGOSDLR](#), [DBGPRCR](#).

AArch64 and AArch32: Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by this bit.

This field resets to a value that is architecturally UNKNOWN.

TDA, bit [9]

Trap Debug Access. Traps EL2, EL1, and EL0 System register accesses to those debug System registers that cannot be trapped using the [MDCR_EL3.TDOSA](#) field. When [MDCR_EL3.TDA](#) is:

- | | |
|---|--|
| 0 | EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA , are not trapped to EL3. |
| 1 | EL0, EL1, and EL2 accesses to the debug registers, other than the registers that can be trapped by MDCR_EL3.TDOSA , are trapped to EL3, from both Security states and both Execution states. |

Traps of AArch32 accesses to [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

Traps of AArch64 accesses to [DBGDTR_EL0](#), [DBGDTRRX_EL0](#), and [DBGDTRTX_EL0](#) are ignored in Debug state.

This field resets to a value that is architecturally UNKNOWN.

Bits [8:7]

Reserved, RES0.

TPM, bit [6]

Trap Performance Monitors accesses. Traps EL2, EL1, and EL0 accesses to all Performance Monitors registers to EL3, from both Security states and both Execution states.

- | | |
|---|--|
| 0 | EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are not trapped to EL3. |
| 1 | EL2, EL1, and EL0 System register accesses to all Performance Monitors registers are trapped to EL3. |

If the Performance Monitors Extension is not implemented, this field is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [5:0]

Reserved, RES0.

Accessing the MDCR_EL3:

To access the MDCR_EL3:

MRS <Xt>, MDCR_EL3 ; Read MDCR_EL3 into Xt
MSR MDCR_EL3, <Xt> ; Write Xt to MDCR_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0011 | 001 |

D7.3.19 MDRAR_EL1, Monitor Debug ROM Address Register

The MDRAR_EL1 characteristics are:

Purpose

Defines the base physical address of a 4KB-aligned memory-mapped debug component, usually a ROM table that locates and describes the memory-mapped debug components in the system. ARMv8 deprecates any use of this register.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

ARMv8 deprecates any use of this register.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDRA==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), read accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register MDRAR_EL1 is architecturally mapped to AArch32 System register [DBGDRAR](#).

Attributes

MDRAR_EL1 is a 64-bit register.

Field descriptions

The MDRAR_EL1 bit assignments are:

Bits [63:48]

Reserved, RES0.

ROMADDR[47:12], bits [47:12]

Bits[47:12] of the ROM table physical address.

If the physical address size in bits (PAsize) is less than 48 then the register bits corresponding to ROMADDR [47:PAsize] are RES0.

Bits [11:0] of the ROM table physical address are zero.

ARM strongly recommends that bits ROMADDR[(PAsize-1):32] are zero in any system that supports AArch32 at the highest implemented Exception level.

In an implementation that includes EL3, ROMADDR is an address in Non-secure memory. It is IMPLEMENTATION DEFINED whether the ROM table is also accessible in Secure memory.

Bits [11:2]

Reserved, RES0.

Valid, bits [1:0]

This field indicates whether the ROM Table address is valid. The permitted values of this field are:

00 ROM Table address is not valid. Software must ignore ROMADDR.

11 ROM Table address is valid.

Other values are reserved.

Accessing the MDRAR_EL1:

To access the MDRAR_EL1:

MRS <Xt>, MDRAR_EL1 ; Read MDRAR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0001 | 0000 | 000 |

D7.3.20 MDSCR_EL1, Monitor Debug System Control Register

The MDSCR_EL1 characteristics are:

Purpose

Main control register for the debug implementation.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `MDSCR_EL2.TDA==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `MDSCR_EL3.TDA==1`, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register MDSCR_EL1 is architecturally mapped to AArch32 System register `DBGDSCRExt`.

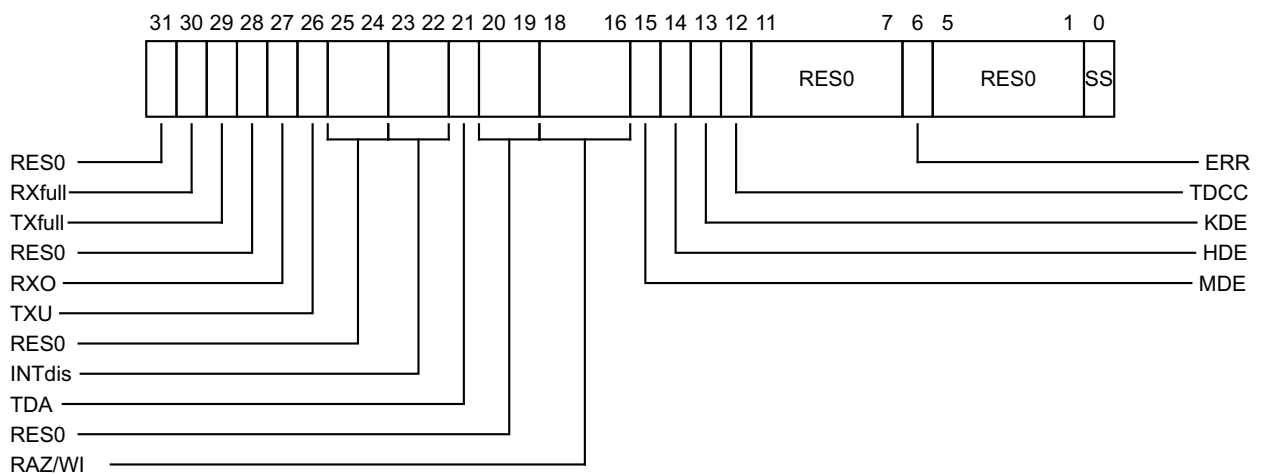

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

MDSCR_EL1 is a 32-bit register.

Field descriptions

The MDSCR_EL1 bit assignments are:

Bit [31]

Reserved, RES0.

RXfull, bit [30]

Used for save/restore of [EDSCR.RXfull](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.RXfull](#).

The architected behavior of this field determines the value it returns after a reset.

TXfull, bit [29]

Used for save/restore of [EDSCR.TXfull](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TXfull](#).

The architected behavior of this field determines the value it returns after a reset.

Bit [28]

Reserved, RES0.

RXO, bit [27]

Used for save/restore of [EDSCR.RXO](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.RXO](#).

The architected behavior of this field determines the value it returns after a reset.

TXU, bit [26]

Used for save/restore of [EDSCR.TXU](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TXU](#).

The architected behavior of this field determines the value it returns after a reset.

Bits [25:24]

Reserved, RES0.

INTdis, bits [23:22]

Used for save/restore of [EDSCR.INTdis](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this field is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this field is RW and holds the value of [EDSCR.INTdis](#).

The architected behavior of this field determines the value it returns after a reset.

TDA, bit [21]

Used for save/restore of [EDSCR.TDA](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.TDA](#).

The architected behavior of this field determines the value it returns after a reset.

Bits [20:19]

Reserved, RES0.

Bits [18:16]

Reserved. Hardware must implement this field as RAZ/WI. Software must not rely on the register reading as zero, and must use a read-modify-write sequence to update the register.

MDE, bit [15]

Monitor debug events. Enable Breakpoint, Watchpoint, and Vector Catch exceptions.

- 0 Breakpoint, Watchpoint, and Vector Catch exceptions disabled.
- 1 Breakpoint, Watchpoint, and Vector Catch exceptions enabled.

This field resets to a value that is architecturally UNKNOWN.

HDE, bit [14]

Used for save/restore of [EDSCR.HDE](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.HDE](#).

The architected behavior of this field determines the value it returns after a reset.

KDE, bit [13]

Local (kernel) debug enable. If EL_D is using AArch64, enable debug exceptions within EL_D . Permitted values are:

- 0 Debug exceptions, other than Breakpoint Instruction exceptions, disabled within EL_D .
- 1 Breakpoint exceptions enabled within EL_D .

RES0 if EL_D is using AArch32.

This field resets to a value that is architecturally UNKNOWN.

TDCC, bit [12]

Traps EL0 accesses to the DCC registers to EL1, from both Execution states:

- 0
 - EL0 using AArch64: EL0 accesses to the [MDCCSR_EL0](#), [DBGDTR_EL0](#), [DBGDTRTX_EL0](#), and [DBGDTRRX_EL0](#) registers are not trapped to EL1.
 - EL0 using AArch32: EL0 accesses to the [DBGDSCRint](#), [DBGDTRRXint](#), [DBGDTRTXint](#), [DBGDIDR](#), [DBGDSAR](#), and [DBGDRAR](#) registers are not trapped to EL1.
- 1
 - EL0 using AArch64: EL0 accesses to the [MDCCSR_EL0](#), [DBGDTR_EL0](#), [DBGDTRTX_EL0](#), and [DBGDTRRX_EL0](#) registers are trapped to EL1.
 - EL0 using AArch32: EL0 accesses to the [DBGDSCRint](#), [DBGDTRRXint](#), [DBGDTRTXint](#), [DBGDIDR](#), [DBGDSAR](#), and [DBGDRAR](#) registers are trapped to EL1.

Note

All accesses to these AArch32 registers are trapped, including LDC and STC accesses to [DBGDTRTXint](#) and [DBGDTRRXint](#), and MRRC accesses to [DBGDSAR](#) and [DBGDRAR](#).

Traps of AArch32 accesses to the [DBGDTRRXint](#) and [DBGDTRTXint](#) are ignored in Debug state.

Traps of AArch64 accesses to [DBGDTR_EL0](#), [DBGDTRRX_EL0](#), and [DBGDTRTX_EL0](#) are ignored in Debug state.

This field resets to a value that is architecturally UNKNOWN.

Bits [11:7]

Reserved, RES0.

ERR, bit [6]

Used for save/restore of [EDSCR.ERR](#).

When [OSLSR_EL1.OSLK](#) == 0 (the OS lock is unlocked), this bit is RO, and software must treat it as UNK/SBZP.

When [OSLSR_EL1.OSLK](#) == 1 (the OS lock is locked), this bit is RW and holds the value of [EDSCR.ERR](#).

The architected behavior of this field determines the value it returns after a reset.

Bits [5:1]

Reserved, RES0.

SS, bit [0]

Software step control bit. If EL_D is using AArch64, enable Software step. Permitted values are:

0 Software step disabled

1 Software step enabled.

RES0 if EL_D is using AArch32.

This field resets to a value that is architecturally UNKNOWN.

Accessing the MDSCR_EL1:

To access the MDSCR_EL1:

MRS <Xt>, MDSCR_EL1 ; Read MDSCR_EL1 into Xt

MSR MDSCR_EL1, <Xt> ; Write Xt to MDSCR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0000 | 0010 | 010 |

D7.3.21 OSDLR_EL1, OS Double Lock Register

The OSDLR_EL1 characteristics are:

Purpose

Used to control the OS Double Lock.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDOSA](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDOSA](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSDLR_EL1 is architecturally mapped to AArch32 System register [DBGOSDLR](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

OSDLR_EL1 is a 32-bit register.

Field descriptions

The OSDLR_EL1 bit assignments are:

Bits [31:1]

Reserved, RES0.

DLK, bit [0]

OS Double Lock control bit. Possible values are:

- 0 OS Double Lock unlocked.
- 1 OS Double Lock locked, if [DBGPRCR_EL1.CORENPDRQ](#) (Core no powerdown request) bit is set to 0 and the PE is in Non-debug state.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the OSDLR_EL1:

To access the OSDLR_EL1:

MRS <Xt>, OSDLR_EL1 ; Read OSDLR_EL1 into Xt
MSR OSDLR_EL1, <Xt> ; Write Xt to OSDLR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0001 | 0011 | 100 |

D7.3.22 OSDTRRX_EL1, OS Lock Data Transfer Register, Receive

The OSDTRRX_EL1 characteristics are:

Purpose

Used for save/restore of [DBGDTRRX_EL0](#). It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

ARM deprecates reads and writes of OSDTRRX_EL1 when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSDTRRX_EL1 is architecturally mapped to AArch32 System register [DBGDTRRXext](#).

Attributes

OSDTRRX_EL1 is a 32-bit register.

Field descriptions

The OSDTRRX_EL1 bit assignments are:

Bits [31:0]

Update DTRRX without side-effect.

Writes to this register update the value in DTRRX and do not change RXfull.

Reads of this register return the last value written to DTRRX and do not change RXfull.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

Accessing the OSDTRRX_EL1:

To access the OSDTRRX_EL1:

MRS <Xt>, OSDTRRX_EL1 ; Read OSDTRRX_EL1 into Xt
MSR OSDTRRX_EL1, <Xt> ; Write Xt to OSDTRRX_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0000 | 0000 | 010 |

D7.3.23 OSDTRTX_EL1, OS Lock Data Transfer Register, Transmit

The OSDTRTX_EL1 characteristics are:

Purpose

Used for save/restore of [DBGDTRTX_EL0](#). It is a component of the Debug Communications Channel.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

ARM deprecates reads and writes of OSDTRTX_EL1 when the OS lock is unlocked.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSDTRTX_EL1 is architecturally mapped to AArch32 System register [DBGDTRTXext](#).

Attributes

OSDTRTX_EL1 is a 32-bit register.

Field descriptions

The OSDTRTX_EL1 bit assignments are:

Bits [31:0]

Return DTRTX without side-effect.

Reads of this register return the value in DTRTX and do not change TXfull.

Writes of this register update the value in DTRTX and do not change TXfull.

For the full behavior of the Debug Communications Channel, see [Chapter H4 The Debug Communication Channel and Instruction Transfer Register](#).

Accessing the OSDTRTX_EL1:

To access the OSDTRTX_EL1:

MRS <Xt>, OSDTRTX_EL1 ; Read OSDTRTX_EL1 into Xt
MSR OSDTRTX_EL1, <Xt> ; Write Xt to OSDTRTX_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0000 | 0011 | 010 |

D7.3.24 OSECCR_EL1, OS Lock Exception Catch Control Register

The OSECCR_EL1 characteristics are:

Purpose

Provides a mechanism for an operating system to access the contents of [EDECCR](#) that are otherwise invisible to software, so it can save/restore the contents of [EDECCR](#) over powerdown on behalf of the external debugger.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDA](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDA](#)==1, accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSECCR_EL1 is architecturally mapped to AArch32 System register [DBGOSECCR](#).

AArch64 System register OSECCR_EL1 is architecturally mapped to External register [EDECCR](#).

If [OSLSR_EL1.OSLK](#) == 0 then OSECCR_EL1 returns an UNKNOWN value on reads and ignores writes.

Attributes

OSECCR_EL1 is a 32-bit register.

Field descriptions

The OSECCR_EL1 bit assignments are:

When [OSLSR.OSLK](#)==1:

EDECCR, bits [31:0]

Used for save/restore to [EDECCR](#) over powerdown.

Accessing the OSECCR_EL1:

To access the OSECCR_EL1:

MRS <Xt>, OSECCR_EL1 ; Read OSECCR_EL1 into Xt
MSR OSECCR_EL1, <Xt> ; Write Xt to OSECCR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0000 | 0110 | 010 |

D7.3.25 OSLAR_EL1, OS Lock Access Register

The OSLAR_EL1 characteristics are:

Purpose

Used to lock or unlock the OS lock.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | WO | WO | WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDOSA](#)==1, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDOSA](#)==1, write accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSLAR_EL1 is architecturally mapped to AArch32 System register [DBGOSLAR](#).

AArch64 System register OSLAR_EL1 is architecturally mapped to External register [OSLAR_EL1](#).

Attributes

OSLAR_EL1 is a 32-bit register.

Field descriptions

The OSLAR_EL1 bit assignments are:

Bits [31:1]

Reserved, RES0.

OSLK, bit [0]

On writes to OSLAR_EL1, bit[0] is copied to the OS lock.

Use [OSLSR_EL1.OSLK](#) to check the current status of the lock.

Accessing the OSLAR_EL1:

To access the OSLAR_EL1:

MSR OSLAR_EL1, <Xt> ; Write Xt to OSLAR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0001 | 0000 | 100 |

D7.3.26 OSLSR_EL1, OS Lock Status Register

The OSLSR_EL1 characteristics are:

Purpose

Provides the status of the OS lock.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TDOSA](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TDOSA](#)==1, read accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register OSLSR_EL1 is architecturally mapped to AArch32 System register [DBGOSLSR](#).

This register is in the Cold reset domain. Some or all RW fields of this register have defined reset values. On a Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Cold reset RW fields in this register reset to architecturally UNKNOWN values. The register is not affected by a Warm reset.

Attributes

OSLSR_EL1 is a 32-bit register.

Field descriptions

The OSLSR_EL1 bit assignments are:

Bits [31:4]

Reserved, RES0.

OSLM[1], bit [3]

See below for description of the OSLM field.

nTT, bit [2]

Not 32-bit access. This bit is always RAZ. It indicates that a 32-bit access is needed to write the key to the OS Lock Access Register.

OSLK, bit [1]

OS Lock Status. The possible values are:

- 0 OS lock unlocked.
- 1 OS lock locked.

The OS lock is locked and unlocked by writing to the OS Lock Access Register.

When this register has an architecturally-defined reset value, this field resets to 1.

OSLM[0], bit [0]

OS lock model implemented. Identifies the form of OS save and restore mechanism implemented. In ARMv8 these bits are as follows:

- 10 OS lock implemented. DBGOSSRR not implemented.
- All other values are reserved.

Accessing the OSLSR_EL1:

To access the OSLSR_EL1:

MRS <Xt>, OSLSR_EL1 ; Read OSLSR_EL1 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 10 | 000 | 0001 | 0001 | 100 |

D7.3.27 SDER32_EL3, AArch32 Secure Debug Enable Register

The SDER32_EL3 characteristics are:

Purpose

Allows access to the AArch32 register [SDER](#) from AArch64 state only. Its value has no effect on execution in AArch64 state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | - | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register SDER32_EL3 is architecturally mapped to AArch32 System register [SDER](#).

If EL1 is AArch64 only, this register is UNDEFINED.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

SDER32_EL3 is a 32-bit register.

Field descriptions

The SDER32_EL3 bit assignments are:

Bits [31:2]

Reserved, RES0.

SUNIDEN, bit [1]

Secure User Non-Invasive Debug Enable:

0 Performance Monitors event counting prohibited in Secure EL0 unless allowed by [MDCR_EL3.SPME](#) or the IMPLEMENTATION DEFINED authentication interface ExternalSecureNoninvasiveDebugEnabled().

1 Performance Monitors event counting allowed in Secure EL0.

This field resets to a value that is architecturally UNKNOWN.

SUIDEN, bit [0]

Secure User Invasive Debug Enable:

- 0 Debug exceptions other than Breakpoint Instruction exceptions from Secure EL0 are disabled, unless enabled by [MDCR_EL3.SPD32](#).
- 1 Debug exceptions from Secure EL0 are enabled.

This field resets to a value that is architecturally UNKNOWN.

Accessing the SDER32_EL3:

To access the SDER32_EL3:

MRS <Xt>, SDER32_EL3 ; Read SDER32_EL3 into Xt
MSR SDER32_EL3, <Xt> ; Write Xt to SDER32_EL3

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 110 | 0001 | 0001 | 001 |

D7.4 Performance Monitors registers

This section lists the Performance Monitoring registers in AArch64.

D7.4.1 PMCCFILTR_EL0, Performance Monitors Cycle Count Filter Register

The PMCCFILTR_EL0 characteristics are:

Purpose

Determines the modes in which the Cycle Counter, [PMCCNTR_EL0](#), increments.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

PMCCFILTR_EL0 can also be accessed by using [PMXEVTYPER_EL0](#) with [PMSELR_EL0.SEL](#) set to 0b11111.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCCFILTR_EL0 is architecturally mapped to AArch32 System register [PMCCFILTR](#).

AArch64 System register PMCCFILTR_EL0 is architecturally mapped to External register [PMCCFILTR_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCFILTR_EL0 is a 32-bit register.

Field descriptions

The PMCCFILTR_EL0 bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count cycles in EL1.

1 Do not count cycles in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

0 Count cycles in EL0.

1 Do not count cycles in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Non-secure EL1 are counted.

Otherwise, cycles in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, cycles in Non-secure EL0 are counted.

Otherwise, cycles in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering bit. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

0 Do not count cycles in EL2.

1 Count cycles in EL2.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

Note

This field is not visible in the AArch32 PMCCFILTR System register.

Bits [25:0]

Reserved, RES0.

Accessing the PMCCFILTR_EL0:

To access the PMCCFILTR_EL0:

MRS <Xt>, PMCCFILTR_EL0 ; Read PMCCFILTR_EL0 into Xt
MSR PMCCFILTR_EL0, <Xt> ; Write Xt to PMCCFILTR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 1111 | 111 |

PMCCFILTR_EL0 can also be accessed by using [PMXEVTYPYPER_EL0](#) with [PMSELR_EL0.SEL](#) set to 0b11111.

D7.4.2 PMCCNTR_EL0, Performance Monitors Cycle Count Register

The PMCCNTR_EL0 characteristics are:

Purpose

Holds the value of the processor Cycle Counter, CCNT, that counts processor clock cycles. See [Time as measured by the Performance Monitors cycle counter on page D5-1835](#) for more information.

[PMCCFILTR_EL0](#) determines the modes and states in which the PMCCNTR_EL0 can increment.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.CR==0](#), and [PMUSERENR_EL0.EN==0](#), read accesses to this register from EL0 are trapped to EL1.
- If [PMUSERENR_EL0.EN==0](#), write accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCCNTR_EL0 is architecturally mapped to AArch32 System register [PMCCNTR](#).

AArch64 System register PMCCNTR_EL0 is architecturally mapped to External register [PMCCNTR_EL0](#).

All counters are subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions. This means that it is CONstrained UNPREDICTABLE whether or not PMCCNTR_EL0 continues to increment when clocks are stopped by WFI and WFE instructions.

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCCNTR_EL0 is a 64-bit register.

Field descriptions

The PMCCNTR_EL0 bit assignments are:

CCNT, bits [63:0]

Cycle count. Depending on the values of [PMCR_ELO](#).{LC,D}, this field increments in one of the following ways:

- Every processor clock cycle.
- Every 64th processor clock cycle.

Writing 1 to [PMCR_ELO](#).C sets this field to 0.

Accessing the PMCCNTR_EL0:

To access the PMCCNTR_EL0:

MRS <Xt>, PMCCNTR_EL0 ; Read PMCCNTR_EL0 into Xt
MSR PMCCNTR_EL0, <Xt> ; Write Xt to PMCCNTR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1101 | 000 |

D7.4.3 PMCEID0_EL0, Performance Monitors Common Event Identification register 0

The PMCEID0_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x000 to 0x01F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to AArch32 System register [PMCEID0](#).

AArch64 System register PMCEID0_EL0[31:0] is architecturally mapped to External register [PMCEID0](#).

Attributes

PMCEID0_EL0 is a 32-bit register.

Field descriptions

The PMCEID0_EL0 bit assignments are:

ID[31:0], bits [31:0]

PMCEID0_EL0[n] maps to event n. For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-1848](#).

For each bit:

- 0 The common event is not implemented.
- 1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID0_EL0:

To access the PMCEID0_EL0:

MRS <Xt>, PMCEID0_EL0 ; Read PMCEID0_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 110 |

D7.4.4 PMCEID1_EL0, Performance Monitors Common Event Identification register 1

The PMCEID1_EL0 characteristics are:

Purpose

Defines which common architectural and common microarchitectural feature events in the range 0x020 to 0x03F are implemented. If a particular bit is set to 1, then the event for that bit is implemented.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure read accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), read accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to AArch32 System register [PMCEID1](#).

AArch64 System register PMCEID1_EL0[31:0] is architecturally mapped to External register [PMCEID1](#).

Attributes

PMCEID1_EL0 is a 32-bit register.

Field descriptions

The PMCEID1_EL0 bit assignments are:

ID[63:32], bits [31:0]

PMCEID1_EL0[n] maps to event (n + 32). For a list of event numbers and descriptions, see [Events, event numbers, and mnemonics on page D5-1848](#).

For each bit:

- 0 The common event is not implemented.
- 1 The common event is implemented.

Bits that map to reserved event numbers are reserved to identify events that might be defined in future revisions to the architecture.

Events that do not require additional features in the PMU can be defined retrospectively, meaning that they can be implemented as part of a PMUv3 implementation.

Accessing the PMCEID1_EL0:

To access the PMCEID1_EL0:

MRS <Xt>, PMCEID1_EL0 ; Read PMCEID1_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 111 |

D7.4.5 PMCNTENCLR_EL0, Performance Monitors Count Enable Clear register

The PMCNTENCLR_EL0 characteristics are:

Purpose

Disables the Cycle Count Register, [PMCCNTR_EL0](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCNTENCLR_EL0 is architecturally mapped to AArch32 System register [PMCNTENCLR](#).

AArch64 System register PMCNTENCLR_EL0 is architecturally mapped to External register [PMCNTENCLR_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENCLR_EL0 is a 32-bit register.

Field descriptions

The PMCNTENCLR_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) disable bit. Disables the cycle counter register. Possible values are:

- 0 When read, means the cycle counter is disabled. When written, has no effect.
- 1 When read, means the cycle counter is enabled. When written, disables the cycle counter.

P<n>, bit [n], for n = 0 to 30

Event counter disable bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR_EL0.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) is enabled. When written, disables [PMEVCNTR<n>_EL0](#).

Accessing the [PMCNTENCLR_EL0](#):

To access the [PMCNTENCLR_EL0](#):

MRS <Xt>, [PMCNTENCLR_EL0](#) ; Read [PMCNTENCLR_EL0](#) into Xt
MSR [PMCNTENCLR_EL0](#), <Xt> ; Write Xt to [PMCNTENCLR_EL0](#)

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 010 |

D7.4.6 PMCNTENSET_EL0, Performance Monitors Count Enable Set register

The PMCNTENSET_EL0 characteristics are:

Purpose

Enables the Cycle Count Register, [PMCCNTR_EL0](#), and any implemented event counters [PMEVCNTR<n>](#). Reading this register shows which counters are enabled.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCNTENSET_EL0 is architecturally mapped to AArch32 System register [PMCNTENSET](#).

AArch64 System register PMCNTENSET_EL0 is architecturally mapped to External register [PMCNTENSET_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCNTENSET_EL0 is a 32-bit register.

Field descriptions

The PMCNTENSET_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) enable bit. Enables the cycle counter register. Possible values are:

- | | |
|---|---|
| 0 | When read, means the cycle counter is disabled. When written, has no effect. |
| 1 | When read, means the cycle counter is enabled. When written, enables the cycle counter. |

P<n>, bit [n], for n = 0 to 30

Event counter enable bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI. When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR_EL0.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) is disabled. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) event counter is enabled. When written, enables [PMEVCNTR<n>_EL0](#).

Accessing the PMCNTENSET_EL0:

To access the PMCNTENSET_EL0:

MRS <Xt>, PMCNTENSET_EL0 ; Read PMCNTENSET_EL0 into Xt
MSR PMCNTENSET_EL0, <Xt> ; Write Xt to PMCNTENSET_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 001 |

D7.4.7 PMCR_EL0, Performance Monitors Control Register

The PMCR_EL0 characteristics are:

Purpose

Provides details of the Performance Monitors implementation, including the number of counters implemented, and configures and controls the counters.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [MDCR_EL2.TPMCR==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [PMUSERENR_EL0.EN==0](#), accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMCR_EL0 is architecturally mapped to AArch32 System register [PMCR](#).

AArch64 System register PMCR_EL0[6:0] is architecturally mapped to External register [PMCR_EL0\[6:0\]](#).

This register is in the Warm reset domain. Some or all RW fields of this register have defined reset values. On a Warm or Cold reset these apply only if the PE resets into an Exception level that is using AArch64. Otherwise, on a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMCR_EL0 is a 32-bit register.

Field descriptions

The PMCR_EL0 bit assignments are:

| | | | | | | | |
|-----|--------|-------|-------|-----|-----|-----|--------|
| 31 | 24 23 | 16 15 | 11 10 | 7 6 | 5 4 | 3 2 | 1 0 |
| IMP | IDCODE | N | RES0 | L | C | D | P E |

IMP, bits [31:24]

Implementer code. This field is RO with an IMPLEMENTATION DEFINED value.

The implementer codes are allocated by ARM. Values have the same interpretation as bits [31:24] of the [MIDR](#).

IDCODE, bits [23:16]

Identification code. This field is RO with an IMPLEMENTATION DEFINED value.

Each implementer must maintain a list of identification codes that is specific to the implementer. A specific implementation is identified by the combination of the implementer code and the identification code.

N, bits [15:11]

Number of event counters. A RO field that indicates the number counters implemented. A value of 0b00000 in this field indicates that only the Cycle Count Register [PMCCNTR_ELO](#) is implemented.

The value of this field is the number of event counters implemented. This value is in the range of 0b00000, in which case only the [PMCCNTR_ELO](#) is implemented, to 0b11111, which indicates that the [PMCCNTR_ELO](#) and 31 event counters are implemented.

In an implementation that includes EL2, reads of this field from Non-secure EL1 and Non-secure EL0 return the value of [MDCR_EL2.HPMN](#).

Bits [10:7]

Reserved, RES0.

LC, bit [6]

Long cycle counter enable. Determines which [PMCCNTR_ELO](#) bit generates an overflow recorded by [PMOVSr\[31\]](#).

0 Cycle counter overflow on increment that changes [PMCCNTR_ELO\[31\]](#) from 1 to 0.

1 Cycle counter overflow on increment that changes [PMCCNTR_ELO\[63\]](#) from 1 to 0.

ARM deprecates use of [PMCR_EL0.LC](#) = 0.

In an AArch64-only implementation, this field is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

DP, bit [5]

Disable cycle counter when event counting is prohibited. The possible values of this bit are:

0 [PMCCNTR_ELO](#), if enabled, counts when event counting is prohibited.

1 [PMCCNTR_ELO](#) does not count when event counting is prohibited.

Counting events is never prohibited in Non-secure state. However, there are some restrictions on counting events in Secure state. For more information about the interaction between the Performance Monitors and EL3, see [Interaction with EL3 on page D5-1841](#).

If EL3 is not implemented, this field is RES0, otherwise it is an RW field.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

X, bit [4]

Enable export of events in an IMPLEMENTATION DEFINED event stream. The possible values of this bit are:

0 Do not export events.

1 Export events where not prohibited.

This field enables the exporting of events over an event bus to another device, for example to an OPTIONAL trace macrocell. If the implementation does not include such an event bus then this field is RAZ/WI, otherwise it is an RW field.

In an implementation that includes an event bus, no events are exported when counting is prohibited.

This field does not affect the generation of Performance Monitors overflow interrupt requests or signaling to a cross-trigger interface (CTI) that can be implemented as signals exported from the PE.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

D, bit [3]

Clock divider. The possible values of this bit are:

- 0 When enabled, [PMCCNTR_EL0](#) counts every clock cycle.
- 1 When enabled, [PMCCNTR_EL0](#) counts once every 64 clock cycles.

In an AArch64-only implementation this field is RES0, otherwise it is an RW field. If [PMCR_EL0.LC](#) == 1, this bit is ignored and the cycle counter counts every clock cycle.

ARM deprecates use of [PMCR_EL0.D](#) = 1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

C, bit [2]

Cycle counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset [PMCCNTR_EL0](#) to zero.

This bit is always RAZ.

Resetting [PMCCNTR_EL0](#) does not clear the [PMCCNTR_EL0](#) overflow bit to 0.

P, bit [1]

Event counter reset. This bit is WO. The effects of writing to this bit are:

- 0 No action.
- 1 Reset all event counters accessible in the current EL, not including [PMCCNTR_EL0](#), to zero.

This bit is always RAZ.

In Non-secure EL0 and EL1, if EL2 is implemented, a write of 1 to this bit does not reset event counters that [MDCR_EL2.HPMN](#) reserves for EL2 use.

In EL2 and EL3, a write of 1 to this bit resets all the event counters.

Resetting the event counters does not clear any overflow bits to 0.

E, bit [0]

Enable. The possible values of this bit are:

- 0 All counters that are accessible at Non-secure EL1, including [PMCCNTR_EL0](#), are disabled.
- 1 All counters that are accessible at Non-secure EL1 are enabled by [PMCNTENSET_EL0](#).

This bit is RW.

If EL2 is implemented, this bit does not affect the operation of event counters that [MDCR_EL2.HPMN](#) reserves for EL2 use.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the PMCR_EL0:

To access the [PMCR_EL0](#):

```
MRS <Xt>, PMCR_EL0 ; Read PMCR_EL0 into Xt
MSR PMCR_EL0, <Xt> ; Write Xt to PMCR_EL0
```

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 000 |

D7.4.8 PMEVCNTR<n>_EL0, Performance Monitors Event Count Registers, n = 0 - 30

The PMEVCNTR<n>_EL0 characteristics are:

Purpose

Holds event counter n, which counts events, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

PMEVCNTR<n>_EL0 can also be accessed by using [PMXVCNTR_EL0](#) with [PMSELR_EL0.SEL](#) set to n.

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVCNTR<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of [PMUSERENR_EL0.EN](#) is 1, if [PMSELR_EL0.SEL](#) is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, [MDCR_EL2.HPMN](#) identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN](#)==0, and [PMUSERENR_EL0.ER](#)==0, read accesses to this register from EL0 are trapped to EL1.
- If [PMUSERENR_EL0.EN](#)==0, write accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMEVCNTR<n>_EL0 is architecturally mapped to AArch32 System register [PMEVCNTR<n>](#).

AArch64 System register PMEVCNTR<n>_EL0 is architecturally mapped to External register [PMEVCNTR<n>_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVCNTR<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVCNTR<n>_EL0 bit assignments are:

Bits [31:0]

Event counter n. Value of event counter n, where n is the number of this register and is a number from 0 to 30.

Accessing the PMEVCNTR<n>_EL0:

To access the PMEVCNTR<n>_EL0:

MRS <Xt>, PMEVCNTR<n>_EL0 ; Read PMEVCNTR<n>_EL0 into Xt, where n is in the range 0 to 30
MSR PMEVCNTR<n>_EL0, <Xt> ; Write Xt to PMEVCNTR<n>_EL0, where n is in the range 0 to 30

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|-----------|--------|
| 11 | 011 | 1110 | 10:n<4:3> | n<2:0> |

PMEVCNTR<n>_EL0 can also be accessed by using [PMXEVCNTR_EL0](#) with [PMSELR_EL0](#).SEL set to the value of <n>.

D7.4.9 PMEVTYPER<n>_EL0, Performance Monitors Event Type Registers, n = 0 - 30

The PMEVTYPER<n>_EL0 characteristics are:

Purpose

Configures event counter n, where n is 0 to 30.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

PMEVTYPER<n>_EL0 can also be accessed by using [PMXEVTYPER_EL0](#) with [PMSELR_EL0.SEL](#) set to n.

If <n> is greater than or equal to the number of accessible counters, reads and writes of PMEVTYPER<n>_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of [PMUSERENR_EL0.EN](#) is 1, if [PMSELR_EL0.SEL](#) is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, [MDCR_EL2.HPMN](#) identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMEVTYPER<n>_EL0 is architecturally mapped to AArch32 System register [PMEVTYPER<n>](#).

AArch64 System register PMEVTYPER<n>_EL0 is architecturally mapped to External register [PMEVTYPER<n>_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMEVTYPER<n>_EL0 is a 32-bit register.

Field descriptions

The PMEVTYPER<n>_EL0 bit assignments are:

P, bit [31]

Privileged filtering bit. Controls counting in EL1. If EL3 is implemented, then counting in Non-secure EL1 is further controlled by the NSK bit. The possible values of this bit are:

- 0 Count events in EL1.
- 1 Do not count events in EL1.

U, bit [30]

User filtering bit. Controls counting in EL0. If EL3 is implemented, then counting in Non-secure EL0 is further controlled by the NSU bit. The possible values of this bit are:

- 0 Count events in EL0.
- 1 Do not count events in EL0.

NSK, bit [29]

Non-secure EL1 (kernel) modes filtering bit. Controls counting in Non-secure EL1. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, events in Non-secure EL1 are counted.

Otherwise, events in Non-secure EL1 are not counted.

NSU, bit [28]

Non-secure EL0 (Unprivileged) filtering. Controls counting in Non-secure EL0. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of U, events in Non-secure EL0 are counted.

Otherwise, events in Non-secure EL0 are not counted.

NSH, bit [27]

Non-secure EL2 (Hypervisor) filtering. Controls counting in Non-secure EL2. If EL2 is not implemented, this bit is RES0.

- 0 Do not count events in EL2.
- 1 Count events in EL2.

M, bit [26]

Secure EL3 filtering bit. If EL3 is not implemented, this bit is RES0.

If the value of this bit is equal to the value of P, cycles in Secure EL3 are counted.

Otherwise, cycles in Secure EL3 are not counted.

Most applications can ignore this field and set its value to 0.

————— Note —————

This field is not visible in the AArch32 PMEVTYPER System register.

MT, bit [25]

Multithreading. When the implementation is multi-threaded, the valid values for this bit are:

- 0 Count events only on controlling PE.
- 1 Count events from any PE with the same affinity at level 1 and above as this PE.

When the implementation is not multi-threaded, this bit is RES0.

Note

- An implementation is described as multi-threaded when the lowest level of affinity consists of logical PEs that are implemented using a multi-threading type approach. That is, the performance of PEs at the lowest affinity level is highly interdependent. On such an implementation, the value of MPIDR_EL1.MT, when read at the highest implemented Exception level, is 1.
 - Events from a different thread of a multithreaded implementation are not Attributable to the thread counting the event.
-

Bits [24:10]

Reserved, RES0.

evtCount, bits [9:0]

Event to count. The event number of the event that is counted by event counter [PMEVCNTR<n>_EL0](#).

Software must program this field with an event that is supported by the PE being programmed.

There are three ranges of event numbers:

- Event numbers in the range 0x000 to 0x03F are common architectural and microarchitectural events.
- Event numbers in the range 0x040 to 0x0BF are ARM recommended common architectural and microarchitectural events.
- Event numbers in the range 0x0C0 to 0x3FF are IMPLEMENTATION DEFINED events.

If evtCount is programmed to an event that is reserved or not supported by the PE, the behavior depends on the event type:

- For the range 0x000 to 0x03F, no events are counted, and the value returned by a direct or external read of the evtCount field is the value written to the field.
- For IMPLEMENTATION DEFINED events, it is UNPREDICTABLE what event, if any, is counted, and the value returned by a direct or external read of the evtCount field is UNKNOWN.

Note

UNPREDICTABLE means the event must not expose privileged information.

ARM recommends that the behavior across a family of implementations is defined such that if a given implementation does not include an event from a set of common IMPLEMENTATION DEFINED events, then no event is counted and the value read back on evtCount is the value written.

Accessing the PMEVTYPER<n>_EL0:

To access the PMEVTYPER<n>_EL0:

MRS <Xt>, PMEVTYPER<n>_EL0 ; Read PMEVTYPER<n>_EL0 into Xt, where n is in the range 0 to 30
MSR PMEVTYPER<n>_EL0, <Xt> ; Write Xt to PMEVTYPER<n>_EL0, where n is in the range 0 to 30

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|-----------|--------|
| 11 | 011 | 1110 | 11:n<4:3> | n<2:0> |

D7.4.10 PMINTENCLR_EL1, Performance Monitors Interrupt Enable Clear register

The PMINTENCLR_EL1 characteristics are:

Purpose

Disables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR_ELO](#), and the event counters [PMEVCNTR<n>_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register PMINTENCLR_EL1 is architecturally mapped to AArch32 System register [PMINTENCLR](#).

AArch64 System register PMINTENCLR_EL1 is architecturally mapped to External register [PMINTENCLR_EL1](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENCLR_EL1 is a 32-bit register.

Field descriptions

The PMINTENCLR_EL1 bit assignments are:

C, bit [31]

[PMCCNTR_ELO](#) overflow interrupt request disable bit. Possible values are:

- | | |
|---|--|
| 0 | When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect. |
| 1 | When read, means the cycle counter overflow interrupt request is enabled. When written, disables the cycle count overflow interrupt request. |

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request disable bit for [PMEVCNTR<n>_ELO](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR_ELO.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is enabled. When written, disables the [PMEVCNTR<n>_ELO](#) interrupt request.

Accessing the PMINTENCLR_EL1:

To access the PMINTENCLR_EL1:

MRS <Xt>, PMINTENCLR_EL1 ; Read PMINTENCLR_EL1 into Xt
MSR PMINTENCLR_EL1, <Xt> ; Write Xt to PMINTENCLR_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1001 | 1110 | 010 |

D7.4.11 PMINTENSET_EL1, Performance Monitors Interrupt Enable Set register

The PMINTENSET_EL1 characteristics are:

Purpose

Enables the generation of interrupt requests on overflows from the Cycle Count Register, [PMCCNTR_ELO](#), and the event counters [PMEVCNTR<n>_ELO](#). Reading the register shows which overflow interrupt requests are enabled.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.

Configurations

AArch64 System register PMINTENSET_EL1 is architecturally mapped to AArch32 System register [PMINTENSET](#).

AArch64 System register PMINTENSET_EL1 is architecturally mapped to External register [PMINTENSET_EL1](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMINTENSET_EL1 is a 32-bit register.

Field descriptions

The PMINTENSET_EL1 bit assignments are:

C, bit [31]

[PMCCNTR_ELO](#) overflow interrupt request enable bit. Possible values are:

- | | |
|---|---|
| 0 | When read, means the cycle counter overflow interrupt request is disabled. When written, has no effect. |
| 1 | When read, means the cycle counter overflow interrupt request is enabled. When written, enables the cycle count overflow interrupt request. |

P<n>, bit [n], for n = 0 to 30

Event counter overflow interrupt request enable bit for [PMEVCNTR<n>_ELO](#).

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR_ELO.N](#).

Bits [30:N] are RAZ/WI.

Possible values are:

- 0 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is disabled. When written, has no effect.
- 1 When read, means that the [PMEVCNTR<n>_ELO](#) event counter interrupt request is enabled. When written, enables the [PMEVCNTR<n>_ELO](#) interrupt request.

Accessing the PMINTENSET_EL1:

To access the PMINTENSET_EL1:

MRS <Xt>, PMINTENSET_EL1 ; Read PMINTENSET_EL1 into Xt
MSR PMINTENSET_EL1, <Xt> ; Write Xt to PMINTENSET_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1001 | 1110 | 001 |

D7.4.12 PMOVSLR_EL0, Performance Monitors Overflow Flag Status Clear Register

The PMOVSLR_EL0 characteristics are:

Purpose

Contains the state of the overflow bit for the Cycle Count Register, [PMCCNTR_EL0](#), and each of the implemented event counters [PMEVCNTR<n>](#). Writing to this register clears these bits.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

This register is accessible at EL0 when [PMUSERENR_EL0.EN](#) is set to 1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMOVSLR_EL0 is architecturally mapped to AArch32 System register [PMOVSr](#).

AArch64 System register PMOVSLR_EL0 is architecturally mapped to External register [PMOVSLR_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSLR_EL0 is a 32-bit register.

Field descriptions

The PMOVSLR_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, clears the overflow bit to 0.

[PMCR_EL0.LC](#) controls whether an overflow is detected from [PMCCNTR_EL0](#)[31] or from [PMCCNTR_EL0](#).

P<n>, bit [n], for n = 0 to 30

Event counter overflow clear bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#).
Otherwise, N is the value in [PMCR_EL0.N](#).

Possible values of each bit are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) has overflowed. When written, clears the [PMEVCNTR<n>_EL0](#) overflow bit to 0.

Accessing the PMOVSCLR_EL0:

To access the PMOVSCLR_EL0:

MRS <Xt>, PMOVSCLR_EL0 ; Read PMOVSCLR_EL0 into Xt
MSR PMOVSCLR_EL0, <Xt> ; Write Xt to PMOVSCLR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 011 |

D7.4.13 PMOVSSET_EL0, Performance Monitors Overflow Flag Status Set register

The PMOVSSET_EL0 characteristics are:

Purpose

Sets the state of the overflow bit for the Cycle Count Register, [PMCCNTR_EL0](#), and each of the implemented event counters [PMEVCNTR<n>](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMOVSSET_EL0 is architecturally mapped to AArch32 System register [PMOVSSET](#).

AArch64 System register PMOVSSET_EL0 is architecturally mapped to External register [PMOVSSET_EL0](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMOVSSET_EL0 is a 32-bit register.

Field descriptions

The PMOVSSET_EL0 bit assignments are:

C, bit [31]

[PMCCNTR_EL0](#) overflow bit. Possible values are:

- 0 When read, means the cycle counter has not overflowed. When written, has no effect.
- 1 When read, means the cycle counter has overflowed. When written, sets the overflow bit to 1.

P<n>, bit [n], for n = 0 to 30

Event counter overflow set bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are RAZ/WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR_EL0.N](#).

Possible values are:

- 0 When read, means that [PMEVCNTR<n>_EL0](#) has not overflowed. When written, has no effect.
- 1 When read, means that [PMEVCNTR<n>_EL0](#) has overflowed. When written, sets the [PMEVCNTR<n>_EL0](#) overflow bit to 1.

Accessing the PMOVSSET_EL0:

To access the PMOVSSET_EL0:

MRS <Xt>, PMOVSSET_EL0 ; Read PMOVSSET_EL0 into Xt
MSR PMOVSSET_EL0, <Xt> ; Write Xt to PMOVSSET_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1110 | 011 |

D7.4.14 PMSELR_EL0, Performance Monitors Event Counter Selection Register

The PMSELR_EL0 characteristics are:

Purpose

Selects the current event counter [PMEVCNTR<n>](#) or the cycle counter, CCNT.

PMSELR_EL0 is used in conjunction with [PMXEVTYPER_EL0](#) to determine the event that increments a selected event counter, and the modes and states in which the selected counter increments.

It is also used in conjunction with [PMXEVCNTR_EL0](#), to determine the value of a selected event counter.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), and [PMUSERENR_EL0.ER==0](#), accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMSELR_EL0 is architecturally mapped to AArch32 System register [PMSELR](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMSELR_EL0 is a 32-bit register.

Field descriptions

The PMSELR_EL0 bit assignments are:

Bits [31:5]

Reserved, RES0.

SEL, bits [4:0]

Selects event counter, [PMEVCNTR<n>](#), where n is the value held in this field. This value identifies which event counter is accessed when a subsequent access to [PMXEVTYPER_EL0](#) or [PMXEVCNTR_EL0](#) occurs.

This field can take any value from 0 (0b00000) to (PMCR.N)-1, or 31 (0b11111).

When PMSELR_EL0.SEL is 0b11111 it selects the cycle counter and:

- A read of the PMXEVTYPYPER_EL0 returns the value of PMCCFILTR_EL0.
- A write of the PMXEVTYPYPER_EL0 writes to PMCCFILTR_EL0.
- A read or write of PMXEVCNTR_EL0 has CONSTRAINED UNPREDICTABLE effects, that can be one of the following:
 - Access to PMXEVCNTR_EL0 is UNDEFINED.
 - Access to PMXEVCNTR_EL0 behaves as a NOP.
 - Access to PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
 - Access to PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.

If this field is set to a value greater than or equal to the number of implemented counters, but not equal to 31, the results of access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 are CONSTRAINED UNPREDICTABLE, and can be one of the following:

- Access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 is UNDEFINED.
- Access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 behaves as a NOP.
- Access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 behaves as if the register is RAZ/WI.
- Access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains an UNKNOWN value.
- Access to PMXEVTYPYPER_EL0 or PMXEVCNTR_EL0 behaves as if the PMSELR_EL0.SEL field contains 0b11111.

Direct reads of this field return an UNKNOWN value.

Accessing the PMSELR_EL0:

To access the PMSELR_EL0:

MRS <Xt>, PMSELR_EL0 ; Read PMSELR_EL0 into Xt
MSR PMSELR_EL0, <Xt> ; Write Xt to PMSELR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 101 |

D7.4.15 PMSWINC_EL0, Performance Monitors Software Increment register

The PMSWINC_EL0 characteristics are:

Purpose

Increments a counter that is configured to count the Software increment event, event 0x00. For more information, see [SW_INCR](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-WO | WO | WO | WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure write accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), write accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN==0](#), and [PMUSERENR_EL0.SW==0](#), write accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMSWINC_EL0 is architecturally mapped to AArch32 System register [PMSWINC](#).

AArch64 System register PMSWINC_EL0 is architecturally mapped to External register [PMSWINC_EL0](#).

Attributes

PMSWINC_EL0 is a 32-bit register.

Field descriptions

The PMSWINC_EL0 bit assignments are:

Bit [31]

Reserved, RES0.

P<n>, bit [n], for n = 0 to 30

Event counter software increment bit for [PMEVCNTR<n>_EL0](#).

Bits [30:N] are WI.

When EL2 is implemented, in Non-secure EL1 and EL0, N is the value in [MDCR_EL2.HPMN](#). Otherwise, N is the value in [PMCR.N](#).

The effects of writing to this bit are:

- 0 No action. The write to this bit is ignored.
- 1 If `PMEVCNTR<n>_EL0` is enabled and configured to count the software increment event, increments `PMEVCNTR<n>_EL0` by 1. If `PMEVCNTR<n>_EL0` is disabled, or not configured to count the software increment event, the write to this bit is ignored.

Accessing the PMSWINC_EL0:

To access the PMSWINC_EL0:

MSR PMSWINC_EL0, <Xt> ; Write Xt to PMSWINC_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1100 | 100 |

D7.4.16 PMUSERENR_EL0, Performance Monitors User Enable Register

The PMUSERENR_EL0 characteristics are:

Purpose

Enables or disables EL0 access to the Performance Monitors.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| RO | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM==1](#), Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM==1](#), accesses to this register from EL0, EL1, and EL2 are trapped to EL3.

Configurations

AArch64 System register PMUSERENR_EL0 is architecturally mapped to AArch32 System register [PMUSERENR](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMUSERENR_EL0 is a 32-bit register.

Field descriptions

The PMUSERENR_EL0 bit assignments are:

Bits [31:4]

Reserved, RES0.

ER, bit [3]

Event counter read trap control:

- 0 EL0 using AArch64: EL0 reads of the [PMXVCNTR_EL0](#) and [PMEVCNTR<n>_EL0](#), and EL0 read/write accesses to the [PMSELR_EL0](#), are trapped to EL1 if PMUSERENR_EL0.EN is also 0.

EL0 using AArch32: EL0 reads of the [PMXEVCNTR](#) and [PMEVCNTR<n>](#), and EL0 read/write accesses to the [PMSELR](#), are trapped to EL1 if [PMUSERENR_EL0.EN](#) is also 0.

- 1 EL0 using AArch64: EL0 reads of the [PMXEVCNTR_EL0](#) and [PMEVCNTR<n>_EL0](#), and EL0 read/write accesses to the [PMSELR_EL0](#), are not trapped to EL1.
- EL0 using AArch32: EL0 reads of the [PMXEVCNTR](#) and [PMEVCNTR<n>](#), and EL0 read/write accesses to the [PMSELR](#), are not trapped to EL1.

CR, bit [2]

Cycle counter read trap control:

- 0 EL0 using AArch64: EL0 read accesses to the [PMCCNTR_EL0](#) are trapped to EL1 if [PMUSERENR_EL0.EN](#) is also 0.
- EL0 using AArch32: EL0 read accesses to the [PMCCNTR](#) are trapped to EL1 if [PMUSERENR_EL0.EN](#) is also 0.
- 1 EL0 using AArch64: EL0 read accesses to the [PMCCNTR_EL0](#) are not trapped to EL1.
- EL0 using AArch32: EL0 read accesses to the [PMCCNTR](#) are not trapped to EL1.

SW, bit [1]

Software Increment write trap control:

- 0 EL0 using AArch64: EL0 writes to the [PMSWINC_EL0](#) are trapped to EL1 if [PMUSERENR_EL0.EN](#) is also 0.
- EL0 using AArch32: EL0 writes to the [PMSWINC](#) are trapped to EL1 if [PMUSERENR_EL0.EN](#) is also 0.
- 1 EL0 using AArch64: EL0 writes to the [PMSWINC_EL0](#) are not trapped to EL1.
- EL0 using AArch32: EL0 writes to the [PMSWINC](#) are not trapped to EL1.

EN, bit [0]

Traps EL0 accesses to the Performance Monitors registers to EL1, from both Execution states:

- 0 EL0 accesses to the Performance Monitors registers are trapped to EL1, unless enabled by one of [PMUSERENR_EL0.{ER, CR, SW}](#).
- 1 EL0 accesses to the Performance Monitors registers are not trapped to EL1. Software can access all PMU registers at EL0.

Note

- The [PMUSERENR_EL0](#) and [PMUSERENR](#) registers are always RO at EL0 and not trapped by this bit.
- EL0 cannot read or write [PMINTENSET_EL1](#) and [PMINTENCLR_EL1](#), or [PMINTENSET](#) and [PMINTENCLR](#).

Accessing the [PMUSERENR_EL0](#):

To access the [PMUSERENR_EL0](#):

MRS <Xt>, [PMUSERENR_EL0](#) ; Read [PMUSERENR_EL0](#) into Xt
MSR [PMUSERENR_EL0](#), <Xt> ; Write Xt to [PMUSERENR_EL0](#)

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1110 | 000 |

D7.4.17 PMXEVNTR_EL0, Performance Monitors Selected Event Count Register

The PMXEVNTR_EL0 characteristics are:

Purpose

Reads or writes the value of the selected event counter, [PMEVCNTR<n>_EL0](#). [PMSELR_EL0](#).SEL determines which event counter is selected.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

If [PMSELR_EL0](#).SEL is greater than or equal to the number of accessible counters then reads and writes of PMXEVNTR_EL0 are CONSTRAINED UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if [PMSELR_EL0](#).SEL has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if [PMSELR_EL0](#).SEL is 31.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of [PMUSERENR_EL0](#).EN is 1, if [PMSELR_EL0](#).SEL is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, [MDCR_EL2](#).HPMN identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2](#).TPM==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3](#).TPM==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0](#).EN==0, and [PMUSERENR_EL0](#).ER==0, read accesses to this register from EL0 are trapped to EL1.
- If [PMUSERENR_EL0](#).EN==0, write accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register PMXEVNTR_EL0 is architecturally mapped to AArch32 System register [PMXEVNTR](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

PMXEVNTR_EL0 is a 32-bit register.

Field descriptions

The PMXEVCNTR_EL0 bit assignments are:

PMEVCNTR<n>, bits [31:0]

Value of the selected event counter, [PMEVCNTR<n>_EL0](#), where n is the value stored in [PMSELR_EL0.SEL](#).

Accessing the PMXEVCNTR_EL0:

To access the PMXEVCNTR_EL0:

MRS <Xt>, PMXEVCNTR_EL0 ; Read PMXEVCNTR_EL0 into Xt
MSR PMXEVCNTR_EL0, <Xt> ; Write Xt to PMXEVCNTR_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1101 | 010 |

D7.4.18 PMXEVTYPER_EL0, Performance Monitors Selected Event Type Register

The PMXEVTYPER_EL0 characteristics are:

Purpose

When [PMSELR_EL0.SEL](#) selects an event counter, this accesses a [PMEVTYPER<n>_EL0](#) register. When [PMSELR_EL0.SEL](#) selects the cycle counter, this accesses [PMCCFILTR_EL0](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

If [PMSELR_EL0.SEL](#) is greater than or equal to the number of accessible counters then reads and writes of [PMXEVTYPER_EL0](#) are CONstrained UNPREDICTABLE, and the following behaviors are permitted:

- Accesses to the register are UNDEFINED.
- Accesses to the register behave as RAZ/WI.
- Accesses to the register execute as a NOP.
- Accesses to the register behave as if [PMSELR_EL0.SEL](#) has an UNKNOWN value less than the number of counters accessible at the current Exception level and Security state.
- Accesses to the register behave as if [PMSELR_EL0.SEL](#) is 31.
- For an access from Non-secure EL1, or an access from Non-secure EL0 when the value of [PMUSERENR_EL0.EN](#) is 1, if [PMSELR_EL0.SEL](#) is greater than or equal to the number of accessible counters but is less than the number of implemented counters, the register access is trapped to EL2.

Note

In an implementation that includes EL2, in Non-secure state at EL0 and EL1, [MDCR_EL2.HPMN](#) identifies the number of accessible counters. Otherwise, the number of accessible counters is the number of implemented counters.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [MDCR_EL2.TPM](#)==1, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If [MDCR_EL3.TPM](#)==1, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If [PMUSERENR_EL0.EN](#)==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register [PMXEVTYPER_EL0](#) is architecturally mapped to AArch32 System register [PMXEVTYPER](#).

This register is in the Warm reset domain. On a Warm or Cold reset RW fields in this register reset to architecturally UNKNOWN values.

Attributes

[PMXEVTYPER_EL0](#) is a 32-bit register.

Field descriptions

The PMXEVTYPER_ELO bit assignments are:

Bits [31:0]

Event type register or [PMCCFILTR_ELO](#).

When [PMSELR_ELO.SEL](#) == 31, this register accesses [PMCCFILTR_ELO](#).

Otherwise, this register accesses [PMEVTYPER<n>_ELO](#) where n is the value in [PMSELR_ELO.SEL](#).

Accessing the PMXEVTYPER_ELO:

To access the PMXEVTYPER_ELO:

MRS <Xt>, PMXEVTYPER_ELO ; Read PMXEVTYPER_ELO into Xt
MSR PMXEVTYPER_ELO, <Xt> ; Write Xt to PMXEVTYPER_ELO

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1001 | 1101 | 001 |

D7.5 Generic Timer registers

This section lists the Generic Timer registers in AArch64.

D7.5.1 CNTFRQ_EL0, Counter-timer Frequency register

The CNTFRQ_EL0 characteristics are:

Purpose

This register is provided so that software can discover the frequency of the system counter. It must be programmed with this value as part of system initialization. The value of the register is not interpreted by hardware.

Usage constraints

If EL1 is the highest exception level implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 |
|-----------|-----|
| Config-RO | RW |

If EL2 is the highest exception level implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----------|-----|----------|
| Config-RO | RO | RW |

If EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RW | RW |

Can only be written at the highest Exception level implemented. For example, if EL3 is the highest implemented Exception level, CNTFRQ_EL0 can only be written at EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If CNTKCTL_EL1.EL0PCTEN==0, and CNTKCTL_EL1.EL0VCTEN==0, read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTFRQ_EL0 is architecturally mapped to AArch32 System register [CNTFRQ](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTFRQ_EL0 is a 32-bit register.

Field descriptions

The CNTFRQ_EL0 bit assignments are:

Bits [31:0]

Clock frequency. Indicates the system counter clock frequency, in Hz.

Accessing the CNTFRQ_EL0:

To access the CNTFRQ_EL0:

MRS <Xt>, CNTFRQ_EL0 ; Read CNTFRQ_EL0 into Xt
MSR CNTFRQ_EL0, <Xt> ; Write Xt to CNTFRQ_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0000 | 000 |

D7.5.2 CNTHCTL_EL2, Counter-timer Hypervisor Control register

The CNTHCTL_EL2 characteristics are:

Purpose

Controls the generation of an event stream from the physical counter, and access from Non-secure EL1 to the physical counter and the Non-secure EL1 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTHCTL_EL2 is architecturally mapped to AArch32 System register [CNTHCTL](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHCTL_EL2 is a 32-bit register.

Field descriptions

The CNTHCTL_EL2 bit assignments are:

Bits [31:8]

Reserved, RES0.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register [CNTPCT_ELO](#) is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register [CNTPCT_ELO](#) trigger bit, defined by EVNTI, generates an event when the event stream is enabled:

- 0 A 0 to 1 transition of the trigger bit triggers an event.
- 1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register [CNTPCT_EL0](#):

- 0 Disables the event stream.
- 1 Enables the event stream.

EL1PCEN, bit [1]

Traps Non-secure EL0 and EL1 accesses to the physical timer registers to EL2.

- 0 From AArch64 state: Non-secure EL0 and EL1 accesses to the [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), and [CNTP_TVAL_EL0](#) are trapped to EL2.
From AArch32 state: Non-secure EL0 and EL1 accesses to the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) are trapped to EL2.
- 1 From AArch64 state: Non-secure EL0 and EL1 accesses to the [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), and [CNTP_TVAL_EL0](#) are not trapped to EL2.
From AArch32 state: Non-secure EL0 and EL1 accesses to the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) are not trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

EL1PCTEN, bit [0]

Traps Non-secure EL0 and EL1 accesses to the physical counter register to EL2.

- 0 From AArch64 state: Non-secure EL0 and EL1 accesses to the [CNTPCT_EL0](#) are trapped to EL2.
From AArch32 state: Non-secure EL0 and EL1 accesses to the [CNTPCT](#) are trapped to EL2.
- 1 From AArch64 state: Non-secure EL0 and EL1 accesses to the [CNTPCT_EL0](#) are not trapped to EL2.
From AArch32 state: Non-secure EL0 and EL1 accesses to the [CNTPCT](#) are not trapped to EL2.

If EL3 is implemented and EL2 is not implemented, behavior is as if this bit is 1 other than for the purpose of a direct read.

Accessing the CNTHCTL_EL2:

To access the CNTHCTL_EL2:

MRS <Xt>, CNTHCTL_EL2 ; Read CNTHCTL_EL2 into Xt
MSR CNTHCTL_EL2, <Xt> ; Write Xt to CNTHCTL_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1110 | 0001 | 000 |

D7.5.3 CNTHP_CTL_EL2, Counter-timer Hypervisor Physical Timer Control register

The CNTHP_CTL_EL2 characteristics are:

Purpose

Control register for the EL2 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTHP_CTL_EL2 is architecturally mapped to AArch32 System register [CNTHP_CTL](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CTL_EL2 is a 32-bit register.

Field descriptions

The CNTHP_CTL_EL2 bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-1884](#) and [Operation of the TimerValue views of the timers on page D6-1885](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked by the IMASK bit.

1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTHP_TVAL_EL2](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTHP_CTL_EL2:

To access the CNTHP_CTL_EL2:

MRS <Xt>, CNTHP_CTL_EL2 ; Read CNTHP_CTL_EL2 into Xt

MSR CNTHP_CTL_EL2, <Xt> ; Write Xt to CNTHP_CTL_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1110 | 0010 | 001 |

D7.5.4 CNTHP_CVAL_EL2, Counter-timer Hypervisor Physical Timer CompareValue register

The CNTHP_CVAL_EL2 characteristics are:

Purpose

Holds the compare value for the EL2 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTHP_CVAL_EL2 is architecturally mapped to AArch32 System register [CNTHP_CVAL](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_CVAL_EL2 is a 64-bit register.

Field descriptions

The CNTHP_CVAL_EL2 bit assignments are:

Bits [63:0]

EL2 physical timer compare value.

Accessing the CNTHP_CVAL_EL2:

To access the CNTHP_CVAL_EL2:

MRS <Xt>, CNTHP_CVAL_EL2 ; Read CNTHP_CVAL_EL2 into Xt
MSR CNTHP_CVAL_EL2, <Xt> ; Write Xt to CNTHP_CVAL_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1110 | 0010 | 010 |

D7.5.5 CNTHP_TVAL_EL2, Counter-timer Hypervisor Physical Timer TimerValue register

The CNTHP_TVAL_EL2 characteristics are:

Purpose

Holds the timer value for the EL2 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Where the value of [CNTHP_CTL_EL2.ENABLE](#) is 0:

- A write to CNTHP_TVAL_EL2 updates the register
- The value held in CNTHP_TVAL_EL2 continues to decrement
- A read of CNTHP_TVAL_EL2 returns an UNKNOWN value.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTHP_TVAL_EL2 is architecturally mapped to AArch32 System register [CNTHP_TVAL](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTHP_TVAL_EL2 is a 32-bit register.

Field descriptions

The CNTHP_TVAL_EL2 bit assignments are:

Bits [31:0]

EL2 physical timer value.

Accessing the CNTHP_TVAL_EL2:

To access the CNTHP_TVAL_EL2:

MRS <Xt>, CNTHP_TVAL_EL2 ; Read CNTHP_TVAL_EL2 into Xt
MSR CNTHP_TVAL_EL2, <Xt> ; Write Xt to CNTHP_TVAL_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1110 | 0010 | 000 |

D7.5.6 CNTKCTL_EL1, Counter-timer Kernel Control register

The CNTKCTL_EL1 characteristics are:

Purpose

Controls the generation of an event stream from the virtual counter, and access from EL0 to the physical counter, virtual counter, EL1 physical timers, and the virtual timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | RW | RW | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTKCTL_EL1 is architecturally mapped to AArch32 System register [CNTKCTL](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTKCTL_EL1 is a 32-bit register.

Field descriptions

The CNTKCTL_EL1 bit assignments are:

Bits [31:10]

Reserved, RES0.

EL0PTEN, bit [9]

Traps EL0 accesses to the physical timer registers to EL1.

0 EL0 using AArch64: EL0 accesses to the [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), and [CNTP_TVAL_EL0](#) registers are trapped to EL1.

EL0 using AArch32: EL0 accesses to the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) registers are trapped to EL1.

1 EL0 using AArch64: EL0 accesses to the [CNTP_CTL_EL0](#), [CNTP_CVAL_EL0](#), and [CNTP_TVAL_EL0](#) registers are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the `CNTP_CTL`, `CNTP_CVAL`, and `CNTP_TVAL` registers are not trapped to EL1.

EL0VTEN, bit [8]

Traps EL0 accesses to the virtual timer registers to EL1.

- 0 EL0 using AArch64: EL0 accesses to the `CNTV_CTL_EL0`, `CNTV_CVAL_EL0`, and `CNTV_TVAL_EL0` registers are trapped to EL1.
EL0 using AArch32: EL0 accesses to the `CNTV_CTL`, `CNTV_CVAL`, and `CNTV_TVAL` registers are trapped to EL1.
- 1 EL0 using AArch64: EL0 accesses to the `CNTV_CTL_EL0`, `CNTV_CVAL_EL0`, and `CNTV_TVAL_EL0` registers are not trapped to EL1.
EL0 using AArch32: EL0 accesses to the `CNTV_CTL`, `CNTV_CVAL`, and `CNTV_TVAL` registers are not trapped to EL1.

EVNTI, bits [7:4]

Selects which bit (0 to 15) of the counter register `CNTVCT_EL0` is the trigger for the event stream generated from that counter, when that stream is enabled.

EVNTDIR, bit [3]

Controls which transition of the counter register `CNTVCT_EL0` trigger bit, defined by `EVNTI`, generates an event when the event stream is enabled:

- 0 A 0 to 1 transition of the trigger bit triggers an event.
- 1 A 1 to 0 transition of the trigger bit triggers an event.

EVNTEN, bit [2]

Enables the generation of an event stream from the counter register `CNTVCT_EL0`:

- 0 Disables the event stream.
- 1 Enables the event stream.

EL0VCTEN, bit [1]

Traps EL0 accesses to the frequency register and virtual counter register to EL1.

- 0 EL0 using AArch64: EL0 accesses to the `CNTVCT_EL0` are trapped to EL1.
EL0 using AArch64: EL0 accesses to the `CNTFRQ_EL0` register are trapped to EL1, if `CNTKCTL_EL1.EL0PCTEN` is also 0.
EL0 using AArch32: EL0 accesses to the `CNTVCT` are trapped to EL1.
EL0 using AArch32: EL0 accesses to the `CNTFRQ` register are trapped to EL1, if `CNTKCTL_EL1.EL0PCTEN` is also 0.
- 1 EL0 using AArch64: EL0 accesses to the `CNTFRQ_EL0` and `CNTVCT_EL0` are not trapped to EL1.
EL0 using AArch32: EL0 accesses to the `CNTFRQ` and `CNTVCT` are not trapped to EL1.

EL0PCTEN, bit [0]

Traps EL0 accesses to the frequency register and physical counter register to EL1.

- 0 EL0 using AArch64: EL0 accesses to the `CNTPCT_EL0` are trapped to EL1.
EL0 using AArch64: EL0 accesses to the `CNTFRQ_EL0` register are trapped to EL1, if `CNTKCTL_EL1.EL0VCTEN` is also 0.
EL0 using AArch32: EL0 accesses to the `CNTPCT` are trapped to EL1.
EL0 using AArch32: EL0 accesses to the `CNTFRQ` and register are trapped to EL1, if `CNTKCTL_EL1.EL0VCTEN` is also 0.
- 1 EL0 using AArch64: EL0 accesses to the `CNTFRQ_EL0` and `CNTPCT_EL0` are not trapped to EL1.

EL0 using AArch32: EL0 accesses to the [CNTFRQ](#) and [CNTPCT](#) are not trapped to EL1.

Accessing the CNTKCTL_EL1:

To access the CNTKCTL_EL1:

MRS <Xt>, CNTKCTL_EL1 ; Read CNTKCTL_EL1 into Xt
MSR CNTKCTL_EL1, <Xt> ; Write Xt to CNTKCTL_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 000 | 1110 | 0001 | 000 |

D7.5.7 CNTP_CTL_EL0, Counter-timer Physical Timer Control register

The CNTP_CTL_EL0 characteristics are:

Purpose

Control register for the EL1 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|-----------|---------|----------|----------------|----------------|
| Config-RW | Config-RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `CNTHCTL_EL2.EL1PCEN==0`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `CNTHCTL_EL2.EL1PCEN==0`, and `CNTKCTL_EL1.ELOPTEN==1`, Non-secure accesses to this register from EL0 are trapped to EL2.
- If `CNTKCTL_EL1.ELOPTEN==0`, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTP_CTL_EL0 is architecturally mapped to AArch32 System register [CNTP_CTL](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CTL_EL0 is a 32-bit register.

Field descriptions

The CNTP_CTL_EL0 bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see *Operation of the CompareValue views of the timers* on page D6-1884 and *Operation of the TimerValue views of the timers* on page D6-1885.

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTP_TVAL_ELO](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTP_CTL_ELO:

To access the CNTP_CTL_ELO:

MRS <Xt>, CNTP_CTL_ELO ; Read CNTP_CTL_ELO into Xt
MSR CNTP_CTL_ELO, <Xt> ; Write Xt to CNTP_CTL_ELO

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0010 | 001 |

D7.5.8 CNTP_CVAL_EL0, Counter-timer Physical Timer CompareValue register

The CNTP_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the EL1 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|-----------|---------|----------|----------------|----------------|
| Config-RW | Config-RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `CNTHCTL_EL2.EL1PCEN==0`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `CNTHCTL_EL2.EL1PCEN==0`, and `CNTKCTL_EL1.ELOPTEN==1`, Non-secure accesses to this register from EL0 are trapped to EL2.
- If `CNTKCTL_EL1.ELOPTEN==0`, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTP_CVAL_EL0 is architecturally mapped to AArch32 System register [CNTP_CVAL](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTP_CVAL_EL0 bit assignments are:

Bits [63:0]

EL1 physical timer compare value.

Accessing the CNTP_CVAL_EL0:

To access the CNTP_CVAL_EL0:

MRS <Xt>, CNTP_CVAL_EL0 ; Read CNTP_CVAL_EL0 into Xt
MSR CNTP_CVAL_EL0, <Xt> ; Write Xt to CNTP_CVAL_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0010 | 010 |

D7.5.9 CNTP_TVAL_EL0, Counter-timer Physical Timer TimerValue register

The CNTP_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the EL1 physical timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|-----------|---------|----------|----------------|----------------|
| Config-RW | Config-RW | RW | RW | RW | RW |

Where the value of CNTP_CTL_EL0.ENABLE is 0:

- A write to CNTP_TVAL_EL0 updates the register
- The value held in CNTP_TVAL_EL0 continues to decrement
- A read of CNTP_TVAL_EL0 returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548*. Subject to the prioritization rules:

- If CNTHCTL_EL2.EL1PCEN==0, Non-secure accesses to this register from EL1 are trapped to EL2.
- If CNTHCTL_EL2.EL1PCEN==0, and CNTKCTL_EL1.ELOPTEN==1, Non-secure accesses to this register from EL0 are trapped to EL2.
- If CNTKCTL_EL1.ELOPTEN==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTP_TVAL_EL0 is architecturally mapped to AArch32 System register CNTP_TVAL.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTP_TVAL_EL0 is a 32-bit register.

Field descriptions

The CNTP_TVAL_EL0 bit assignments are:

Bits [31:0]

EL1 physical timer value.

Accessing the CNTP_TVAL_EL0:

To access the CNTP_TVAL_EL0:

MRS <Xt>, CNTP_TVAL_EL0 ; Read CNTP_TVAL_EL0 into Xt
MSR CNTP_TVAL_EL0, <Xt> ; Write Xt to CNTP_TVAL_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0010 | 000 |

D7.5.10 CNTPCT_EL0, Counter-timer Physical Count register

The CNTPCT_EL0 characteristics are:

Purpose

Holds the 64-bit physical count value.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|-----------|---------|----------|----------------|----------------|
| Config-RO | Config-RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64* on page D1-1548. Subject to the prioritization rules:

- If CNTHCTL_EL2.EL1PCTEN==0, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If CNTHCTL_EL2.EL1PCTEN==0, and CNTKCTL_EL1.EL0PCTEN==1, Non-secure read accesses to this register from EL0 are trapped to EL2.
- If CNTKCTL_EL1.EL0PCTEN==0, read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTPCT_EL0 is architecturally mapped to AArch32 System register CNTPCT.

Attributes

CNPCT_EL0 is a 64-bit register.

Field descriptions

The CNTPCT_EL0 bit assignments are:

Bits [63:0]

Physical count value.

Accessing the CNTPCT_EL0:

To access the CNTPCT_EL0:

MRS <Xt>, CNTPCT_EL0 ; Read CNTPCT_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0000 | 001 |

D7.5.11 CNTPS_CTL_EL1, Counter-timer Physical Secure Timer Control register

The CNTPS_CTL_EL1 characteristics are:

Purpose

Control register for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|-----------|----------|----------------|----------------|
| - | - | Config-RW | - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `SCR_EL3.ST==0`, Secure accesses to this register from EL1 are trapped to EL3.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_CTL_EL1 is a 32-bit register.

Field descriptions

The CNTPS_CTL_EL1 bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-1884](#) and [Operation of the TimerValue views of the timers on page D6-1885](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

0 Timer interrupt is not masked by the IMASK bit.

1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

0 Timer disabled.

1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTPS_TVAL_EL1](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTPS_CTL_EL1:

To access the CNTPS_CTL_EL1:

MRS <Xt>, CNTPS_CTL_EL1 ; Read CNTPS_CTL_EL1 into Xt

MSR CNTPS_CTL_EL1, <Xt> ; Write Xt to CNTPS_CTL_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 111 | 1110 | 0010 | 001 |

D7.5.12 CNTPS_CVAL_EL1, Counter-timer Physical Secure Timer CompareValue register

The CNTPS_CVAL_EL1 characteristics are:

Purpose

Holds the compare value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|-----------|----------|----------------|----------------|
| - | - | Config-RW | - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `SCR_EL3.ST==0`, Secure accesses to this register from EL1 are trapped to EL3.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_CVAL_EL1 is a 64-bit register.

Field descriptions

The CNTPS_CVAL_EL1 bit assignments are:

Bits [63:0]

Secure physical timer compare value.

Accessing the CNTPS_CVAL_EL1:

To access the CNTPS_CVAL_EL1:

MRS <Xt>, CNTPS_CVAL_EL1 ; Read CNTPS_CVAL_EL1 into Xt
MSR CNTPS_CVAL_EL1, <Xt> ; Write Xt to CNTPS_CVAL_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 111 | 1110 | 0010 | 010 |

D7.5.13 CNTPS_TVAL_EL1, Counter-timer Physical Secure Timer TimerValue register

The CNTPS_TVAL_EL1 characteristics are:

Purpose

Holds the timer value for the secure physical timer, usually accessible at EL3 but configurably accessible at EL1 in Secure state.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|-----------|----------|----------------|----------------|
| - | - | Config-RW | - | RW | RW |

Where the value of CNTPS_CTL_EL1.ENABLE is 0:

- A write to CNTPS_TVAL_EL1 updates the register
- The value held in CNTPS_TVAL_EL1 continues to decrement
- A read of CNTPS_TVAL_EL1 returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If SCR_EL3.ST==0, Secure accesses to this register from EL1 are trapped to EL3.

Configurations

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTPS_TVAL_EL1 is a 32-bit register.

Field descriptions

The CNTPS_TVAL_EL1 bit assignments are:

Bits [31:0]

Secure physical timer value.

Accessing the CNTPS_TVAL_EL1:

To access the CNTPS_TVAL_EL1:

MRS <Xt>, CNTPS_TVAL_EL1 ; Read CNTPS_TVAL_EL1 into Xt
MSR CNTPS_TVAL_EL1, <Xt> ; Write Xt to CNTPS_TVAL_EL1

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 111 | 1110 | 0010 | 000 |

D7.5.14 CNTV_CTL_EL0, Counter-timer Virtual Timer Control register

The CNTV_CTL_EL0 characteristics are:

Purpose

Control register for the virtual timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If `CNTKCTL_EL1.ELOVTEN==0`, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTV_CTL_EL0 is architecturally mapped to AArch32 System register [CNTV_CTL](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CTL_EL0 is a 32-bit register.

Field descriptions

The CNTV_CTL_EL0 bit assignments are:

Bits [31:3]

Reserved, RES0.

ISTATUS, bit [2]

The status of the timer. This bit indicates whether the timer condition is met:

- 0 Timer condition is not met.
- 1 Timer condition is met.

When the value of the ENABLE bit is 1, ISTATUS indicates whether the timer condition is met. ISTATUS takes no account of the value of the IMASK bit. If the value of ISTATUS is 1 and the value of IMASK is 0 then the timer interrupt is asserted.

When the value of the ENABLE bit is 0, the ISTATUS field is UNKNOWN.

For more information see [Operation of the CompareValue views of the timers on page D6-1884](#) and [Operation of the TimerValue views of the timers on page D6-1885](#).

This bit is read-only.

IMASK, bit [1]

Timer interrupt mask bit. Permitted values are:

- 0 Timer interrupt is not masked by the IMASK bit.
- 1 Timer interrupt is masked by the IMASK bit.

For more information, see the description of the ISTATUS bit.

ENABLE, bit [0]

Enables the timer. Permitted values are:

- 0 Timer disabled.
- 1 Timer enabled.

Setting this bit to 0 disables the timer output signal, but the timer value accessible from [CNTV_TVAL_ELO](#) continues to count down.

———— **Note** —————

Disabling the output signal might be a power-saving option.

Accessing the CNTV_CTL_ELO:

To access the CNTV_CTL_ELO:

MRS <Xt>, CNTV_CTL_ELO ; Read CNTV_CTL_ELO into Xt
MSR CNTV_CTL_ELO, <Xt> ; Write Xt to CNTV_CTL_ELO

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0011 | 001 |

D7.5.15 CNTV_CVAL_EL0, Counter-timer Virtual Timer CompareValue register

The CNTV_CVAL_EL0 characteristics are:

Purpose

Holds the compare value for the virtual timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If CNTKCTL_EL1.ELOVTEN==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTV_CVAL_EL0 is architecturally mapped to AArch32 System register CNTV_CVAL.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_CVAL_EL0 is a 64-bit register.

Field descriptions

The CNTV_CVAL_EL0 bit assignments are:

Bits [63:0]

Virtual timer compare value.

Accessing the CNTV_CVAL_EL0:

To access the CNTV_CVAL_EL0:

MRS <Xt>, CNTV_CVAL_EL0 ; Read CNTV_CVAL_EL0 into Xt
MSR CNTV_CVAL_EL0, <Xt> ; Write Xt to CNTV_CVAL_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0011 | 010 |

D7.5.16 CNTV_TVAL_EL0, Counter-timer Virtual Timer TimerValue register

The CNTV_TVAL_EL0 characteristics are:

Purpose

Holds the timer value for the virtual timer.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RW | RW | RW | RW | RW | RW |

Where the value of CNTV_CTL_EL0.ENABLE is 0:

- A write to CNTV_TVAL_EL0 updates the register
- The value held in CNTV_TVAL_EL0 continues to decrement
- A read of CNTV_TVAL_EL0 returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548*. Subject to the prioritization rules:

- If CNTKCTL_EL1.EL0VTEN==0, accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTV_TVAL_EL0 is architecturally mapped to AArch32 System register CNTV_TVAL.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTV_TVAL_EL0 is a 32-bit register.

Field descriptions

The CNTV_TVAL_EL0 bit assignments are:

Bits [31:0]

Virtual timer value.

Accessing the CNTV_TVAL_EL0:

To access the CNTV_TVAL_EL0:

MRS <Xt>, CNTV_TVAL_EL0 ; Read CNTV_TVAL_EL0 into Xt
MSR CNTV_TVAL_EL0, <Xt> ; Write Xt to CNTV_TVAL_EL0

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0011 | 000 |

D7.5.17 CNTVCT_EL0, Counter-timer Virtual Count register

The CNTVCT_EL0 characteristics are:

Purpose

Holds the 64-bit virtual count value. The virtual count value is equal to the physical count value visible in [CNTPCT_EL0](#) minus the virtual offset visible in [CNTVOFF_EL2](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|----------|---------|----------|----------------|----------------|
| Config-RO | RO | RO | RO | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#). Subject to the prioritization rules:

- If [CNTKCTL_EL1.ELOVCTEN](#)==0, read accesses to this register from EL0 are trapped to EL1.

Configurations

AArch64 System register CNTVCT_EL0 is architecturally mapped to AArch32 System register [CNTVCT](#).

The virtual count value is equal to the physical count value visible in [CNTPCT_EL0](#) minus the virtual offset visible in [CNTVOFF_EL2](#).

When EL2 is not implemented, [CNTVOFF_EL2](#) is RES0, and the value of this register is the same as the value of [CNTPCT_EL0](#).

Attributes

CNTVCT_EL0 is a 64-bit register.

Field descriptions

The CNTVCT_EL0 bit assignments are:

Bits [63:0]

Virtual count value.

Accessing the CNTVCT_EL0:

To access the CNTVCT_EL0:

MRS <Xt>, CNTVCT_EL0 ; Read CNTVCT_EL0 into Xt

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 011 | 1110 | 0000 | 010 |

D7.5.18 CNTVOFF_EL2, Counter-timer Virtual Offset register

The CNTVOFF_EL2 characteristics are:

Purpose

Holds the 64-bit virtual offset. This is the offset between the physical count value visible in [CNTPCT_EL0](#) and the virtual count value visible in [CNTVCT_EL0](#).

Usage constraints

This register is accessible as follows:

| EL0 | EL1 (NS) | EL1 (S) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----|----------|---------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch64 System register CNTVOFF_EL2 is architecturally mapped to AArch32 System register [CNTVOFF](#).

If EL2 is not implemented, this register is RES0 from EL3 and the virtual counter uses a fixed virtual offset of zero.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CNTVOFF_EL2 is a 64-bit register.

Field descriptions

The CNTVOFF_EL2 bit assignments are:

Bits [63:0]

Virtual offset.

Accessing the CNTVOFF_EL2:

To access the CNTVOFF_EL2:

MRS <Xt>, CNTVOFF_EL2 ; Read CNTVOFF_EL2 into Xt
MSR CNTVOFF_EL2, <Xt> ; Write Xt to CNTVOFF_EL2

Register access is encoded as follows:

| op0 | op1 | CRn | CRm | op2 |
|-----|-----|------|------|-----|
| 11 | 100 | 1110 | 0000 | 011 |

Part E

The AArch32 Application Level Architecture

Chapter E1

The AArch32 Application Level Programmers' Model

This chapter gives an Application level description of the programmers' model for software executing in AArch32 state. This means it describes execution in EL0 when EL0 is using AArch32. It contains the following sections:

- [About the Application level programmers' model on page E1-2288.](#)
- [The Application level programmers' model in AArch32 state on page E1-2289.](#)
- [Advanced SIMD and floating-point instructions on page E1-2300.](#)
- [About the AArch32 System register interface on page E1-2312.](#)
- [Exceptions on page E1-2313.](#)

E1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for the development of applications that will execute in AArch32 state.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implementation, the architecture supports multiple levels of execution privilege. These privilege levels are indicated by different *Exception levels* that number upwards from EL0, where EL0 corresponds to the lowest privilege level and is often described as *unprivileged*. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see [ARMv8 architectural concepts on page A1-33](#).

System software determines the Exception level, and therefore the level of privilege, at which application software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged. This has the following effects:

- It means that the operating system can allocate system resources to an application in a unique or shared manner.
- It provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some System level understanding is helpful, and if appropriate it gives a reference to the System level description.

When included in an implementation:

- EL3 provides two Security states, Secure and Non-secure. Secure state provides additional hardware features that support the development of secure applications.
- EL2 provides virtualization of operation in Non-secure state.

However, application level software is generally unaware of its Security state, and of any virtualization. For more information, see [The ARMv8-A security model on page G1-3789](#) and [The effect of implementing EL2 on the Exception model on page G1-3794](#).

———— **Note** ————

- When an implementation includes EL3, application and operating system software normally executes in Non-secure state.
- EL2, that provides the virtualization features, is implemented only in Non-secure state.
- Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at EL1 as *privileged* execution.
- In this manual, the terms *CONSTRAINED UNPREDICTABLE, IMPLEMENTATION DEFINED, OPTIONAL, RES0, RES1, UNDEFINED, UNKNOWN, and UNPREDICTABLE* have ARM-specific meanings, as defined in the [Glossary](#). In body text, these terms are shown in SMALL CAPS, for example IMPLEMENTATION DEFINED.

E1.2 The Application level programmers' model in AArch32 state

The following sections give more information about the Application level programmers' model in AArch32 state:

- [Instruction sets, arithmetic operations, and register files.](#)
- [Core data types and arithmetic in AArch32 state.](#)
- [The general-purpose registers, and the PC, in AArch32 state on page E1-2291.](#)
- [Process state, PSTATE on page E1-2294.](#)
- [Jazelle support on page E1-2299.](#)

E1.2.1 Instruction sets, arithmetic operations, and register files

The A32 and T32 instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on a register file of sixteen 32-bit registers, that are comprised of the AArch32 general-purpose registers and the PC. As described in [The general-purpose registers, and the PC, in AArch32 state on page E1-2291](#), these registers include the registers SP (R13) and LR (R14), which have specialized uses. [Core data types and arithmetic in AArch32 state](#) gives more information about these operations.

In addition, an implementation that implements the T32 and A32 instruction sets includes both:

- Scalar floating-point instructions.
- The Advanced SIMD vector instructions.

Floating-point and vector instructions operate on a separate common register file, described in [The SIMD and floating-point register file on page E1-2300](#). [Advanced SIMD and floating-point instructions on page E1-2300](#) gives more information about these instructions.

E1.2.2 Core data types and arithmetic in AArch32 state

When executing in AArch32 state, a PE supports the following data types in memory:

| | |
|-------------------|----------|
| Byte | 8 bits |
| Halfword | 16 bits |
| Word | 32 bits |
| Doubleword | 64 bits. |

PE registers are 32 bits in size. The instruction sets provide instructions that use the following data types for data held in registers:

- 32-bit pointers.
- Unsigned or signed 32-bit integers.
- Unsigned 16-bit or 8-bit integers, held in zero-extended form.
- Signed 16-bit or 8-bit integers, held in sign-extended form.
- Two 16-bit integers packed into a register.
- Four 8-bit integers packed into a register.
- Unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

———— **Note** ————

For information about the atomicity of memory accesses see [Atomicity in the ARM architecture on page E2-2328](#).

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to 2^N-1 , using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range $-2^{(N-1)}$ to $+2^{(N-1)}-1$, using two's complement format.

The instructions that operate on packed halfwords or bytes include some multiply instructions that use only one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

———— **Note** —————

These SIMD instructions operate on values held in the general-purpose registers, and must not be confused with the Advanced SIMD instructions that operate on a separate register file that provides registers of up to 128 bits.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

Integer arithmetic

The instruction set provides a wide range of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and divisions. The pseudocode described in [Appendix K11 ARM Pseudocode Definition](#) defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in [Operators on page K11-5638](#).
- By use of pseudocode helper functions defined in the main text. See [Appendix K12 Pseudocode Index](#).
- By a sequence of the form:
 1. Use of the `SInt()`, `UInt()`, and `Int()` built-in functions defined in [Converting bitstrings to integers on page K11-5651](#) to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
 2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
 3. Use of either the bitstring extraction operator defined in [Bitstring concatenation and slicing on page K11-5639](#) or of the saturation helper functions described in [Pseudocode description of saturation on page E1-2291](#) to convert an unbounded integer result into a bitstring result that can be written to a register.

Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

The `LSL()` pseudocode function moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

The `LSR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

The `ASR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right The `ROR()` pseudocode function moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

The `RRX()` pseudocode function moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.

Pseudocode description of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand or operands otherwise. For the definition of these operations, see [Addition and subtraction on page K11-5640](#).

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions can be synthesized from this status information. In pseudocode the `AddWithCarry()` function provides an addition with a carry input and a set of output Condition flags including carry output and overflow:

An important property of the `AddWithCarry()` function is that if:

```
(result, nzcvc) = AddWithCarry(x, NOT(y), carry_in)
```

Then:

- If `carry_in == '1'`, then `result == x-y` with:
 - `nzcvc<0> == '1'` if signed overflow occurred during the subtraction.
 - `nzcvc<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if $x \geq y$.
- If `carry_in == '0'`, then `result == x-y-1` with:
 - `nzcvc<0> == '1'` if signed overflow occurred during the subtraction.
 - `nzcvc<1> == '1'` if unsigned borrow did not occur during the subtraction, that is, if $x \geq y$.

Taken together, this means that the `carry_in` and `nzcvc<1>` output in `AddWithCarry()` calls can act as NOT borrow flags for subtractions as well as carry flags for additions.

Pseudocode description of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N . This is supported in pseudocode by:

- The `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred.
- The `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

`SatQ(i, N, unsigned)` returns either `UnsignedSatQ(i, N)` or `SignedSatQ(i, N)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat(i, N)` or `SignedSat(i, N)` depending on the value of its third argument.

E1.2.3 The general-purpose registers, and the PC, in AArch32 state

In the AArch32 Application level view, a PE has:

- Fifteen general-purpose 32-bit registers, R0 to R14, of which R13 and R14 have alternative names reflecting how they are, or can be, used:
 - R13 is usually identified as SP.
 - R14 is usually identified as LR.
- The PC (*program counter*), that can be described as R15.

The specialized uses of the SP (R13), LR (R14), and PC (R15) are:

SP, the stack pointer

The PE uses SP as a pointer to the active stack.

In the T32 instruction set, some instructions cannot access SP. Instructions that can access SP can use SP as a general-purpose register.

The A32 instruction set provides more general access to SP, and it can be used as a general-purpose register.

———— Note —————

Using SP for any purpose other than as a stack pointer might break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

Software can refer to SP as R13.

LR, the link register

The link register can be used to hold return link information, and some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. Software can refer to LR as R14.

PC, the program counter

- When executing an A32 instruction, PC reads as the address of the current instruction plus 8.
- When executing a T32 instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most T32 instructions cannot access PC.

The A32 instruction set provides more general access to the PC, and many A32 instructions can use the PC as a general-purpose register. However, ARM deprecates the use of PC for any purpose other than as the program counter. See [Writing to the PC](#) for more information.

Software can refer to PC as R15.

See [AArch32 general-purpose registers, the PC, and the Special-purpose registers](#) on page G1-3801 for the system level view of these registers.

———— Note —————

In general, ARM strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to *registers R8 to R15*, rather than to *registers R8 to R12, the SP, LR and PC*. These two descriptions of the group of registers have exactly the same meaning.

Writing to the PC

In the A32 and T32 instruction sets, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In T32 state, the following 16-bit T32 instruction encodings branch to the value written to the PC:
 - Encoding T2 of *ADD, ADDS (register)* on page F5-2573.
 - Encoding T1 of *MOV, MOVS (register)* on page F5-2815.

The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.

- The B, BL, CBNZ, CBZ, CHKA, HB, HBL, HBLP, HBP, TBB, and TBH instructions remain in the same instruction set state and branch to the value written to the PC.

The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.

- The BLX (immediate) instruction switches between A32 and T32 states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.
- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
 - BLX (register), BX, and BXJ.
 - LDR instructions with <Rt> equal to the PC.
 - POP and all forms of LDM except LDM (exception return), when the register list includes the PC.
 - In A32 state only, ADC, ADD, ADR, AND, ASR (immediate), BIC, EOR, LSL (immediate), LSR (immediate), MOV, MVN, ORR, ROR (immediate), RRX, RSB, RSC, SBC, and SUB instructions with <Rd> equal to the PC and without flag-setting specified.

For details of how an interworking address specifies the new instruction set state and instruction address, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

———— **Note** —————

The register-shifted register instructions, that are available only in the A32 instruction set and are summarized in [Data-processing register \(register shift\) on page F4-2513](#), are CONSTRAINED UNPREDICTABLE if they attempt to write to the PC, see [Using R15 on page K1-5457](#).

- Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see [Exception return to an Exception level using AArch32 on page G1-3834](#).
- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry.

Pseudocode description of operations on the AArch32 general-purpose registers and the PC

In pseudocode, the uses of the `R[]` function, with an index parameter `n`, are:

- Reading or writing R0-R12, SP, and LR, using `n = 0-12, 13, and 14` respectively.
- Reading the PC, using `n = 15`.

[Pseudocode description of general-purpose register and PC operations on page G1-3803](#) describes accesses to these registers.

Descriptions of A32 store instructions that store the PC value use the `PCStoreValue()` pseudocode function to specify the PC value stored by the instruction.

Writing an address to the PC causes either a simple branch to that address or an *interworking* branch that also selects the instruction set to execute after the branch. A simple branch is performed by the `BranchWritePC()` function.

An interworking branch is performed by the `BXWritePC()` function.

The `LoadWritePC()` and `ALUWritePC()` functions are used for two cases where the behavior was systematically modified between architecture versions.

E1.2.4 Process state, PSTATE

Process state or **PSTATE** is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

———— Note —————

In this chapter, references to **PSTATE** link to the more appropriate of:

- The Application-level view of **PSTATE** given in this section.
- The System-level description in *Process state, PSTATE* on page G1-3805.

The following **PSTATE** information is accessible at EL0:

The condition flags

Flag-setting instructions set these. They are:

- N** Negative condition flag. If the result of the instruction is regarded as a two's complement signed integer, the PE sets this to:
- 1 if the result is negative.
 - 0 if the result is positive or zero.
- Z** Zero condition flag. Set to:
- 1 if the result of the instruction is zero.
 - 0 otherwise.
- A result of zero often indicates an equal result from a comparison.
- C** Carry condition flag. Set to:
- 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.
 - 0 otherwise.
- V** Overflow condition flag. Set to:
- 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.
 - 0 otherwise.

Conditional instructions test the N, Z, C, and V condition flags, combining them with the *condition code* for the instruction, to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution, see *Conditional execution* on page F2-2407.

The overflow or saturation flag

- Q** Some instructions can set this. For those instructions that can, the PE:
- Sets it to 1 if the instruction indicates overflow or saturation.
 - Leaves it unchanged otherwise.

For more information, see *Pseudocode description of saturation* on page E1-2291.

The greater than or equal flags

- GE[3:0]** The instructions described in *Parallel addition and subtraction instructions* on page F1-2378 update these to indicate the results from individual bytes or halfwords of the operation. These flags can control a later SEL instruction. For more information, see *SEL* on page F5-2964.

PSTATE also contains *PE state controls*. There is no direct access to these from application level instructions, but they can be changed by side-effects of application level instructions. They are:

Instruction set state

J, T The current instruction set state, as shown in [Table E1-1](#). In ARMv8, the J bit is RES0, see the Note in this section.

Table E1-1 PSTATE.{J, T} encoding

| J | T | Instruction set state |
|---|---|-----------------------|
| 0 | 0 | A32 |
| 0 | 1 | T32 |

A32 The PE is executing the A32 instruction set, summarized in [Chapter F4 The A32 Instruction Set Encoding](#).

T32 The PE is executing the T32 instruction set, summarized in [Chapter F3 The T32 Instruction Set Encoding](#).

Note

Encoding with J==1 before ARMv8, Jazelle and T32EE states

In previous versions of the ARM architecture, the encoding {1, 0} selected Jazelle state, and encoding {1, 1} selected T32EE state. ARMv8 does not support either of these states, and these are encodings for unimplemented instruction set states, see [Unimplemented instruction sets on page G1-3810](#). ARMv8 AArch32 state requires a Trivial Jazelle implementation, see [Trivial implementation of the Jazelle extension on page G1-3810](#).

The IT block state

IT[7:0] The If-Then controls for the T32 IT instruction, that applies to the *IT block* of instructions that immediately follow the IT instruction. See [IT on page F5-2681](#) for a description of the IT instruction and its associated IT block.
For more information about the use of **PSTATE.IT** see [Use of PSTATE.IT on page E1-2297](#).

Endianness mapping

E For data accesses, controls the endianness:

0 Little-endian.

1 Big-endian.

If an implementation does not provide:

- Big-endian support for data accesses, this bit is RES0.
- Little-endian support for data accesses, this bit is RES1.

Instruction fetches are always little-endian, and ignore **PSTATE.E**.

Accessing PSTATE fields at EL0

The following sections describe which **PSTATE** fields can be directly accessed at EL0, and how they can be accessed:

- [The Application Program Status Register, APSR.](#)
- [The SETEND instruction.](#)

The Application Program Status Register, APSR

At EL0, some **PSTATE** fields can be accessed using the Special-purpose *Application Program Status Register* (APSR). The APSR can be directly read using the **MRS** instruction, and directly written using the **MSR (register)** and **MSR (immediate)** instructions.

The APSR bit assignments are:

Condition flags

N, Z, C, V, bits [31:28]

The **PSTATE** condition flags.

Q, bit [27] The **PSTATE** overflow or saturation flag.

Bits[26:24] Reserved, RAZ/SBZP. Software can use MSR instructions that write the top byte of the APSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23:20, 15:0]

Reserved bits that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at EL1 or higher. However, application level software that writes to the APSR must treat reserved bits as *Do-Not-Modify* (DNM) bits. For more information about the reserved bits, see [The Current Program Status Register, CPSR on page G1-3807](#).

GE[3:0], bits [19:16]

The **PSTATE** greater than or equal flags.

The other **PSTATE** fields cannot be accessed by using the APSR.

The system level alias for the APSR is the **CPSR**. The **CPSR** is a superset of the APSR. See [The Current Program Status Register, CPSR on page G1-3807](#).

Writes to the **PSTATE** fields have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the APSR write. This means they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate **PSTATE.E**:

SETEND BE Sets **PSTATE.E** to 1, for big-endian operation.
 SETEND LE Sets **PSTATE.E** to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see [SETEND on page F5-2966](#). ARM deprecates use of the SETEND instruction.

Use of PSTATE.IT

PSTATE.IT provides the If-Then controls for the T32 IT instruction, that applies to the *IT block* of instructions that immediately follow the IT instruction.

PSTATE.IT divides into two subfields:

IT[7:5] Holds the *base condition* for the current IT block. The base condition is the top three bits of the condition code specified by the <firstcond> field of the IT instruction.

IT[4:0] Encodes:

- Implicitly, the size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is indicated by the position of the least significant 1 in this field, as shown in [Table E1-2](#).
- For each instruction in the IT block, the least significant bit of the condition code. This is encoded in the IT block entries that [Table E1-2](#) shows as Nx.

———— **Note** —————

Changing the least significant bit of a condition code from 0 to 1 has the effect of inverting the condition code.

Both subfields are all zeros when no IT block is active.

When an IT instruction is executed, PSTATE.IT is set according to the <firstcond> field of the instruction and the *Then* and *Else* (T and E) parameters in the instruction, see [IT on page F5-2681](#). This means that, on executing an IT instruction, the initial state of PSTATE.IT depends on the number of instructions in the IT block, as [Table E1-2](#) shows:

Table E1-2 Initial state of PSTATE.IT on executing an IT instruction

| Number of instructions in IT block | PSTATE.IT bits ^a | | | | | | Notes |
|------------------------------------|-----------------------------|-----|-----|-----|-----|-----|-----------------------|
| | [7:5] | [4] | [3] | [2] | [1] | [0] | |
| 4 | cond_base | N1 | N2 | N3 | N4 | 1 | - |
| 3 | cond_base | N1 | N2 | N3 | 1 | 0 | - |
| 2 | cond_base | N1 | N2 | 1 | 0 | 0 | - |
| 1 | cond_base | N1 | 1 | 0 | 0 | 0 | - |
| Not executing an IT instruction | 000 | 0 | 0 | 0 | 0 | 0 | No IT block is active |

a. Combinations of the IT bits not shown in this table are reserved.

In [Table E1-2](#), N1 refers to the first instruction in the IT block, and N2, N3, and N4 refer to the second, third, and fourth instructions in the IT block if they are present,

When permitted, an instruction in an IT block is conditional, see [Conditional instructions on page F1-2369](#) and [Conditional execution on page F2-2407](#). The condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, PSTATE.IT[4:0] is left-shifted by one bit, so that PSTATE[4] always relates to the next instruction to be executed. [Table E1-3 on page E1-2298](#) shows how PSTATE.IT during the execution of an IT instruction with four instructions in the IT block.

Table E1-3 Updates to `PSTATE.IT` when executing an IT instruction with a four-instruction IT block

| IT block instruction being executed | <code>PSTATE.IT</code> bits | | | | | | Notes |
|-------------------------------------|-----------------------------|-----|-----|-----|-----|-----|-----------------------|
| | [7:5] | [4] | [3] | [2] | [1] | [0] | |
| First | cond_base | N1 | N2 | N3 | N4 | 1 | - |
| Second | cond_base | N2 | N3 | N4 | 1 | 0 | - |
| Third | cond_base | N3 | N4 | 1 | 0 | 0 | - |
| Fourth | cond_base | N4 | 1 | 0 | 0 | 0 | - |
| Not executing an IT instruction | 000 | 0 | 0 | 0 | 0 | 0 | No IT block is active |

A few instructions, for example BKPT, cannot be conditional and therefore are always executed ignoring the current value of `PSTATE.IT`.

For details of what happens if an instruction in an IT block takes an exception, see [Overview of exception entry on page G1-3819](#).

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in `PSTATE.IT` advancing to execution where no IT block is active.

For performance reasons, ARMv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see [Partial deprecation of IT on page K5-5531](#). In addition, implementations can provide a set of ITD control fields, `SCTLR.ITD`, `SCTLR_EL1.ITD`, and `HSCTLR.ITD`, to disable these deprecated uses, making them UNDEFINED. When an implementation includes ITD control fields, [Changes to an ITD control by an instruction in an IT block](#) describes the permitted CONSTRAINED UNPREDICTABLE behaviors if an instruction in an IT block changes the value of an ITD control to disable the use of the IT instruction.

On a branch or an exception return, if `PSTATE.IT` is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is CONSTRAINED UNPREDICTABLE.

`PSTATE.IT` affects instruction execution only in T32 state. In A32 state, `PSTATE.IT` must be `0b00000000`, otherwise the behavior is CONSTRAINED UNPREDICTABLE.

For more information see [CONSTRAINED UNPREDICTABLE behavior associated with IT instructions and PSTATE.IT on page K1-5458](#).

Changes to an ITD control by an instruction in an IT block

In an implementation that includes `SCTLR.ITD`, `SCTLR_EL1.ITD`, and `HSCTLR.ITD` controls, if an instruction in an IT block changes an ITD control so that the IT instruction using the IT block would be disabled, then one of the following behaviors applies:

- The change to the ITD field, once synchronized, has no effect on the execution of instructions in the current IT block, but applies only to any subsequent execution of an IT instruction to which the control applies.
- Synchronizing the change to the ITD field guarantees that all bits of `PSTATE.IT` are cleared to 0.

In addition, after the change to the ITD field has been synchronized, any remaining instructions in the IT block that would be made UNDEFINED by the new value of ITD are either:

- Executed normally.
- Treated as UNDEFINED.

The choice between the options described in this section is determined by the implementation, and any choice can vary between different changes to an ITD control by an instruction in an IT block.

Pseudocode description of PSTATE PE state fields

The pseudocode function [CurrentInstrSet\(\)](#) returns the current instruction set. The pseudocode function [SelectInstrSet\(\)](#) selects a new instruction set.

[PSTATE.IT](#) advances after normal execution of an IT block instruction. This is described by the [AArch32.ITAdvance\(\)](#) pseudocode function.

The pseudocode function [InITBlock\(\)](#) tests whether the current instruction is in an IT block. The pseudocode function [LastInITBlock\(\)](#) tests whether the current instruction is the last instruction in an IT block.

The [BigEndian\(\)](#) pseudocode function tests whether big-endian data memory accesses are currently selected.

E1.2.5 Jazelle support

ARMv8 requires AArch32 state to include a trivial implementation of the Jazelle extension, as described in [Trivial implementation of the Jazelle extension on page G1-3810](#).

E1.3 Advanced SIMD and floating-point instructions

In general, ARMv8 requires implementation of Advanced SIMD and floating-point instructions in the T32 and A32 instruction sets, but see [Implications of not including Advanced SIMD and floating-point support on page E1-2306](#).

The Advanced SIMD instructions perform packed *Single Instruction Multiple Data* (SIMD) operations, either integer or single-precision floating-point. The floating-point instructions perform single-precision or double-precision scalar floating-point operations.

These instructions permit *floating-point exceptions*, such as overflow or division by zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. ARMv8 also optionally supports the trapping of floating-point exceptions, see [Trapping of floating-point exceptions on page E1-2302](#). For more information about floating-point exceptions see [Floating-point exceptions on page E1-2303](#).

The floating-point and Advanced SIMD instructions also provide conversion functions in both directions between half-precision floating-point and single-precision floating-point.

Some Advanced SIMD instructions support polynomial arithmetic over $\{0, 1\}$, as described in [Polynomial arithmetic over \$\{0, 1\}\$ on page A1-45](#).

For system level information about the Advanced SIMD and Floating-point implementation see [Advanced SIMD and floating-point support on page G1-3880](#).

The following sections give more information about the Advanced SIMD and floating-point instructions:

- [Floating-point standards, and terminology on page A1-48](#).
- [The SIMD and floating-point register file](#).
- [Data types supported by the Advanced SIMD implementation on page E1-2302](#).
- [Advanced SIMD and floating-point System registers on page E1-2302](#).
- [Trapping of floating-point exceptions on page E1-2302](#).
- [Floating-point data types and arithmetic on page E1-2303](#).
- [Floating-point exceptions on page E1-2303](#).
- [Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2306](#).
- [Implications of not including Advanced SIMD and floating-point support on page E1-2306](#).
- [Pseudocode description of floating-point operations on page E1-2306](#).

E1.3.1 The SIMD and floating-point register file

The Advanced SIMD and floating-point instructions use the same register file, that comprises 32 registers. This is distinct from the register file that holds the general-purpose registers and the PC.

The Advanced SIMD and floating-point views of the register file are different. The following sections describe these different views. [Figure E1-1 on page E1-2301](#) shows the views of the register file, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the register file

Advanced SIMD can view this register file as:

- Sixteen 128-bit quadword registers, Q0-Q15.
- Thirty-two 64-bit doubleword registers, D0-D31.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in D0 and D1 and a 128-bit vector in Q1.

Floating-point views of the register file

The Advanced SIMD and floating-point register file consists of thirty-two doubleword registers, that can be viewed as:

- Thirty-two 64-bit doubleword registers, D0-D31. This view is also available to Advanced SIMD instructions.
- Thirty-two 32-bit single word registers, S0-S31. Only half of the set is accessible in this view.

The two views can be used simultaneously.

SIMD and Floating-point register file mapping onto registers

Figure E1-1 shows the different views of the SIMD and floating-point register file, and the relationship between them.

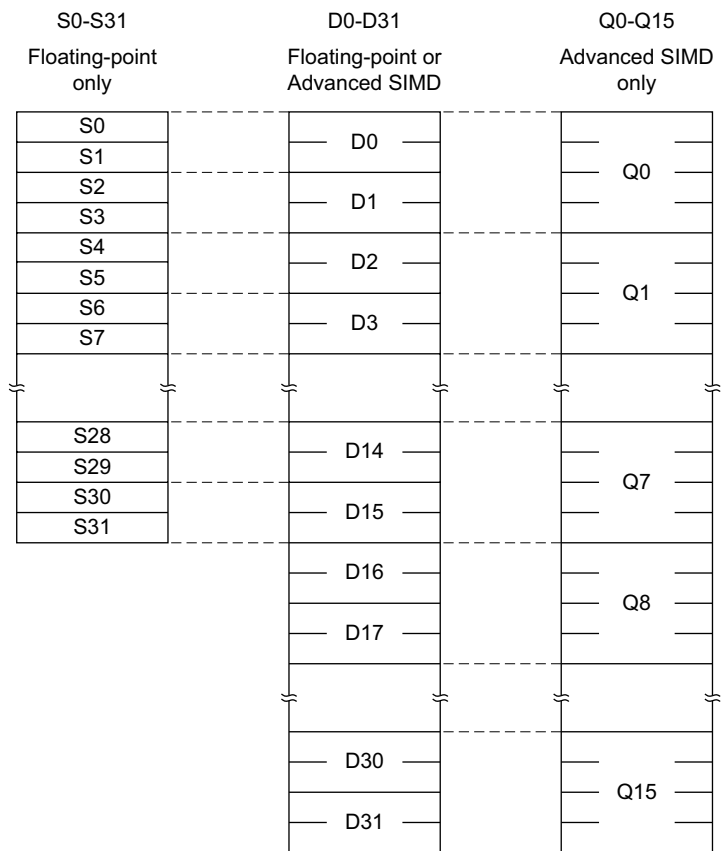

Figure E1-1 SIMD and floating-point register file, AArch32 operation

The mapping between the registers is as follows:

- S<2n> maps to the least significant half of D<n>.
- S<2n+1> maps to the most significant half of D<n>.
- D<2n> maps to the least significant half of Q<n>.
- D<2n+1> maps to the most significant half of Q<n>.

For example, software can access the least significant half of the elements of a vector in Q6 by referring to D12, and the most significant half of the elements by referring to D13.

Pseudocode description of the SIMD and Floating-point register file

The functions `_Dclone`, `S[]`, and `D[]` provide the S0-S31, D0-D31, and Q0-Q15 views of the Advanced SIMD and floating-point registers:

The `Din[]` function returns a Doubleword register from the `_Dclone[]` copy of the SIMD and Floating-point register file, and the `Qin[]` function returns a Quadword register from that register file.

———— Note —————

The `CheckAdvSIMDEnabled()` function copies the `D[]` register file to `_Dclone[]`, see [Pseudocode description of enabling SIMD and floating-point functionality on page G1-3919](#).

E1.3.2 Data types supported by the Advanced SIMD implementation

Advanced SIMD instructions can operate on integer and floating-point data, and the implementation defines a set of data types that support the required data formats. [Vector formats in AArch32 state on page A1-38](#) describes these formats.

Advanced SIMD vectors

In an implementation that includes support for Advanced SIMD operation, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. In [Vector formats in AArch32 state on page A1-38](#), [Figure A1-3 on page A1-40](#) shows the Advanced SIMD vector formats.

Pseudocode description of Advanced SIMD vectors

The pseudocode function `E1em[]` accesses the element of a specified index and size in a vector.

E1.3.3 Advanced SIMD and floating-point System registers

The Advanced SIMD and floating-point instructions have a shared register space for System registers. Only one register in this space is accessible at the Application level, see [FPSCR, Floating-Point Status and Control Register on page G6-4335](#).

Writes to the `FPSCR` can have side-effects on various aspects of PE operation. All of these side-effects are synchronous to the `FPSCR` write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See [Advanced SIMD and floating-point System registers on page G1-3882](#) for the system level view of the registers.

These registers can be described as the *SIMD and floating-point System registers*.

E1.3.4 Trapping of floating-point exceptions

It is IMPLEMENTATION DEFINED whether the floating-point implementation supports the trapping of floating-point exceptions:

- If it does, the `FPSCR`.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable the exception traps.
- Otherwise, the `FPSCR` trap bits are RES0.

Trapped exception handling never causes the corresponding cumulative exception bit of the `FPSCR` to be set to 1. If this behavior is desired, the trap handler routine must use a read, modify, write sequence on the `FPSCR` to set the cumulative exception bit.

E1.3.5 Floating-point data types and arithmetic

The T32 and A32 floating-point instructions support single-precision (32-bit) and double-precision (64-bit) data types and arithmetic as defined by the IEEE 754 floating-point standard. They also support the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types.

ARM standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the restrictions described in *Floating-point and Advanced SIMD support* on page A1-46, including supporting only the input and output values described in *ARM standard floating-point input and output values* on page A1-49.

The AArch32 Advanced SIMD instructions support only single-precision ARM standard floating-point arithmetic.

The following sections describe the Advanced SIMD and floating-point formats:

- [Half-precision floating-point formats](#) on page A1-40.
- [Single-precision floating-point format](#) on page A1-42.
- [Double-precision floating-point format](#) on page A1-43.

The following sections describe features of Advanced SIMD and floating-point processing:

- [Flush-to-zero](#) on page A1-49.
- [NaN handling and the Default NaN](#) on page A1-50.

E1.3.6 Floating-point exceptions

ARM Advanced SIMD and floating-point instructions record the following floating-point exceptions in the **FPSCR** cumulative bits, unless the floating-point exception is trapped and generates an exception:

FPSCR.IOC Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:

- $(\text{infinity}) \times 0$.
- $(+\text{infinity}) + (-\text{infinity})$.

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as $(0 \times \text{infinity})$, and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in *Floating-point negation and absolute value* on page E1-2307.

FPSCR.DZC Division by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Division by Zero from occurring, and a denormalized divisor is treated as zero and causes Division by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions sets the DZC bit.

FPSCR.OFC Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

FPSCR.UFC Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow exception to occur are different in Flush-to-zero mode. For details, see [Flush-to-zero](#) on page A1-49.

FPSCR.IXC Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact exception to occur are different in Flush-to-zero mode. For details, see [Flush-to-zero](#) on page A1-49.

FPSCR.IDC Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in *Flush-to-zero* on page A1-49.

For Advanced SIMD instructions, and for floating-point instructions when floating-point exception trapping is not supported, these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

For floating-point instructions when floating-point exception trapping is supported:

- These exceptions can be trapped, by setting trap enable bits in the **FPSCR**, see *Trapping of floating-point exceptions* on page E1-2302 and *Floating-point exception traps* on page G1-3883, and:
 - When a trap is not enabled the corresponding floating-point exception updates the corresponding **FPSCR** cumulative bit does not generate an exception.
 - When a trap is enabled the corresponding floating-point exception does not update the **FPSCR**, but generates an exception. In this case, bits in the **FPEXC** indicate which floating-point exceptions have occurred.
- The definition of the Underflow exception is different in the trapped and cumulative exception cases. In the trapped case the definition is:
 - The trapped Underflow exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in *Combinations of floating-point exceptions* on page E1-2305.
- For Invalid Operation exceptions, for details of which quiet NaN is produced as the default result see *NaN handling and the Default NaN* on page A1-50.
- For Overflow exceptions, the sign bit of the default result is determined normally for the overflowing operation.
- For Division by Zero exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.

Table E1-4 shows the results of untrapped floating-point exceptions. That table uses the following abbreviations:

- MaxNorm** The maximum normalized number of the destination precision.
RM Round towards Minus Infinity mode, as defined in the IEEE 754 standard.
RN Round to Nearest mode, as defined in the IEEE 754 standard.
RP Round towards Plus Infinity mode, as defined in the IEEE 754 standard.
RZ Round towards Zero mode, as defined in the IEEE 754 standard.

For more information about the IEEE 754 descriptions of the rounding modes see *Floating-point standards, and terminology* on page A1-48.

Table E1-4 Results of untrapped floating-point exceptions

| Exception type | Default result for positive sign | Default result for negative sign |
|------------------------|---------------------------------------|---------------------------------------|
| IOC, Invalid Operation | Quiet NaN | Quiet NaN |
| DZC, Division by Zero | +infinity | -infinity |
| OFC, Overflow | RN, RP: +infinity RM, RZ: +MaxNorm | RN, RM: -infinity RP, RZ: -MaxNorm |
| UFC, Underflow | Normal rounded result | Normal rounded result |
| IXC, Inexact | Normal rounded result | Normal rounded result |
| IDC, Input Denormal | Normal rounded result | Normal rounded result |

Combinations of floating-point exceptions

Many pseudocode functions perform *floating-point operations*, including `FixedToFP()`, `FPAAdd()`, `FPCompare()`, `FPCompareEQ()`, `FPCompareGE()`, `FPCompareGT()`, `FPDiv()`, `FPMaX()`, `FPMIn()`, `FPMu1()`, `FPMu1Add()`, `FPRecipEstimate()`, `FPRecipStep()`, `FPRSqrtEstimate()`, `FPRSqrtStep()`, `FPSqrt()`, `FPSub()`, and `FPToFixed()`. All of these operations can generate floating-point exceptions.

Note

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- They cannot generate floating-point exceptions.
 - The floating-point operation behavior described in the following sections does not apply to them:
 - [Flush-to-zero on page A1-49](#).
 - [NaN handling and the Default NaN on page A1-50](#).
-

More than one exception can occur on the same operation. The only combinations of exceptions that can occur are:

- Overflow with Inexact.
- Underflow with Inexact.
- Input Denormal with other exceptions.

When none of the exceptions caused by an operation is trapped, any exception that occurs causes the associated cumulative bit in the `FPSCR` to be set.

When one or more exceptions caused by an operation are trapped, the behavior of the instruction depends on the priority of the exceptions. The Inexact exception is treated as lowest priority, and Input Denormal as highest priority:

- If the higher priority exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether any information about the lower priority exception is provided.

Note

Information about the lower priority exception might be provided in:

- The `FPEXC`, if the exception generated by the trap is taken to an Exception level that is using AArch32.
- The `ESR_ELx.ISS` field, if the exception generated by the trap is taken to an Exception level that is using AArch64.

However, information might be provided in another IMPLEMENTATION DEFINED way, for example using an IMPLEMENTATION DEFINED register.

Apart from this, the lower priority exception is ignored in this case.

- If the higher priority exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, an exception on one operation is treated as higher priority than an exception on another operation if the occurrence of the second exception depends on the result of the first operation. Otherwise, it is CONstrained UNPREDICTABLE which exception is treated as higher priority.

For example, a `VMLA.F32` instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any exception on the multiplication. The same applies to Invalid Operation exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is CONstrained UNPREDICTABLE which of an Input Denormal exception on the addition and an exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal exception does not depend on the result of the multiplication. The same applies to an Invalid Operation exception on the addition caused by the addend being a signaling NaN.

———— **Note** ————

The VFMA instruction performs a vector addition and a vector multiplication as a single operation. The VFMS instruction performs a vector subtraction and a vector multiplication as a single operation.

E1.3.7 Controls of Advanced SIMD operation that do not apply to floating-point operation

ARMv7 permitted implementation of either, both, or neither of the Advanced SIMD and floating-point additions to the base instruction set, and provided some controls that applied to the Advanced SIMD functionality but not to the floating-point functionality. In ARMv8, Advanced SIMD functionality cannot be separated from floating-point functionality, but in AArch32 state these controls function as they did in ARMv7. This means they apply only to the following instructions and instruction encodings:

- All instructions with encodings defined in:
 - [Advanced SIMD data-processing on page F3-2454](#), for the T32 instruction set.
 - [Advanced SIMD data-processing on page F4-2541](#), for the A32 instruction set.
- All instructions with encodings defined in:
 - [Advanced SIMD element or structure Load/Store on page F3-2479](#), for the T32 instruction set.
 - [Advanced SIMD element or structure Load/Store on page F4-2553](#), for the A32 instruction set.
- The form of the VDUP instruction described in [VDUP \(general-purpose register\) on page F6-3394](#).
- The byte and halfword forms of the VMOV instructions described in each of:
 - [VMOV \(general-purpose register to scalar\) on page F6-3512](#).
 - [VMOV \(scalar to general-purpose register\) on page F6-3516](#).

The controls of this functionality are:

- The CPACR.ASEDIS field.
- The HCPTR.TASE field.

In an implementation that supports Advanced SIMD functionality, support for each of these controls is optional:

- If the CPACR.ASEDIS control is not supported then the CPACR.ASEDIS field is RAZ/WI. This is equivalent to the control permitting the execution of Advanced SIMD instructions at EL1 and EL0.
- If the HCPTR.TASE control is not supported then the HCPTR.TASE field is RAZ/WI. This means the HCPTR does not provide a control that can trap Non-secure execution of Advanced SIMD instructions to Hyp mode.

E1.3.8 Implications of not including Advanced SIMD and floating-point support

In general, ARMv8 requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets. Exceptionally, for implementation targeting specialized markets, ARM might produce or license an ARMv8-A implementation that does not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- Each of the CPACR.{cp10, cp11} fields is RES0.
- The CPACR.ASEDIS bit is RES0.
- Each of the HCPTR.{TASE, TCP10, TCP11} fields is RES1.
- Each of the NSACR.{NSASEDIS, cp10, cp11} fields is RES0.
- The FPEXC register is UNDEFINED.

E1.3.9 Pseudocode description of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the ARMv8 architecture:

- [Generation of specific floating-point values on page E1-2307](#).
- [Floating-point negation and absolute value on page E1-2307](#).

- [Floating-point value unpacking](#).
- [Floating-point exception and NaN handling](#).
- [Floating-point rounding](#).
- [Selection of ARM standard floating-point arithmetic](#) on page E1-2308.
- [Floating-point comparisons](#) on page E1-2308.
- [Floating-point maximum and minimum](#) on page E1-2308.
- [Floating-point addition and subtraction](#) on page E1-2308.
- [Floating-point multiplication and division](#) on page E1-2308.
- [Floating-point fused multiply-add](#) on page E1-2308.
- [Floating-point reciprocal estimate and step](#) on page E1-2308.
- [Floating-point square root](#) on page E1-2309.
- [Floating-point reciprocal square root estimate and step](#) on page E1-2309.
- [Floating-point conversions](#) on page E1-2311.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The `sign` argument is '0' for the positive version and '1' for the negative version:

- [FPInfinity\(\)](#).
- [FPMaxNormal\(\)](#).
- [FPZero\(\)](#).
- [FPTwo\(\)](#).
- [FPThree\(\)](#).
- [FPDefaultNaN\(\)](#).

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

The floating-point negation operation is described by the pseudocode function [FPNeg\(\)](#). The floating-point absolute value operation is described by the pseudocode function [FPAbs\(\)](#).

Floating-point value unpacking

The [FPUnpack\(\)](#) function determines the type of a floating-point number, defined by [FPType{}](#), and its numerical value. It also does flush-to-zero processing on input operands.

Floating-point exception and NaN handling

The [FPProcessException\(\)](#) procedure checks whether a floating-point exception is trapped, and handles it accordingly. The floating-point exception types are defined by [FPExc{}](#).

The [FPProcessNaN\(\)](#) function processes a NaN operand, producing the correct result value and generating an Invalid Operation exception if necessary. The [FPProcessNaNs\(\)](#) function performs the standard NaN processing for a two-operand operation. The [FPProcessNaNs3\(\)](#) function performs the standard NaN processing for a three-operand operation.

Floating-point rounding

The [FPRound\(\)](#) function rounds and encodes a floating-point result value to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

Selection of ARM standard floating-point arithmetic

The `StandardFPSCRValue()` function returns the `FPSCR` value that selects ARM standard floating-point arithmetic. Most of the arithmetic functions have a Boolean `fpscr_controlled` argument that is `TRUE` for Floating-point operations and `FALSE` for Advanced SIMD operations, and that selects between using the real `FPSCR` value and this value.

Floating-point comparisons

The `FPCompare()` function compares two floating-point numbers, producing a {N, Z, C, V} Condition flags result as shown in [Table E1-5](#):

Table E1-5 Effect of a Floating-point comparison on the Condition flags

| Comparison result | N | Z | C | V |
|-------------------|---|---|---|---|
| Equal | 0 | 1 | 1 | 0 |
| Less than | 1 | 0 | 0 | 0 |
| Greater than | 0 | 0 | 1 | 0 |
| Unordered | 0 | 0 | 1 | 1 |

This result defines the operation of the `VCMP` floating-point instruction. The `VCMP` instruction writes these flag values in the `FPSCR`. After using a `VMRS` instruction to transfer them to the `APSR`, they can control conditional execution as shown in [Table F2-1 on page F2-2407](#).

The `FPCompareEQ()`, `FPCompareGE()`, and `FPCompareGT()` functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

Floating-point maximum and minimum

The `FPMaX()` function returns the maximum of two floating-point numbers. The `FPMiN()` function returns the minimum of two floating-point numbers.

Floating-point addition and subtraction

The `FPAdd()` function adds two floating-point numbers. The `FPSub()` function subtracts one floating-point number from another floating-point number.

Floating-point multiplication and division

The `FPMu1()` function multiplies two floating-point numbers. The `FPDiv()` function divides one floating-point number by another floating-point number.

Floating-point fused multiply-add

The `FPMu1Add()` function performs a floating-point fused multiply-add.

Floating-point reciprocal estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The `VRECP` instruction produces the initial estimate of the reciprocal. It uses the pseudocode functions:

- `FPRecipEstimate()`.
- `UnsignedRecipEstimate()`. This pseudocode function calls the C function `recip_estimate()`:

```
double recip_estimate(double a)
{
```

```

int q, s;
double r;
q = (int)(a * 512.0);          /* a in units of 1/512 rounded down */
r = 1.0 / (((double)q + 0.5) / 512.0); /* reciprocal r */
s = (int)(256.0 * r + 0.5);    /* r in units of 1/256 rounded to nearest */
return (double)s / 256.0;
}

```

Table E1-6 shows the results where input values are out of range.

Table E1-6 VRECPE results for out of range inputs

| Number type | Input Vm[i] | Result Vd[i] |
|----------------|--------------------------------|-----------------------------|
| Integer | $\leq 0x7FFFFFFF$ | 0xFFFFFFFF |
| Floating-point | NaN | Default NaN |
| Floating-point | ± 0 or denormalized number | \pm infinity ^a |
| Floating-point | \pm infinity | ± 0 |
| Floating-point | Absolute value $\geq 2^{126}$ | ± 0 |

a. `FPSR.DZC` is set to 1

The Newton-Raphson iteration:

$$x_{n+1} = x_n(2 - dx_n)$$

converges to $(1/d)$ if x_0 is the result of VRECPE applied to d .

The VRECPS instruction performs a $(2 - op1 \times op2)$ calculation and can be used with a multiplication to perform a step of this iteration. The functionality of this instruction is defined by the `FPRcipStep()` pseudocode function.

Table E1-7 shows the results where input values are out of range.

Table E1-7 VRECPS results for out of range inputs

| Input Vn[i] | Input Vm[i] | Result Vd[i] |
|----------------------------------|----------------------------------|--------------|
| Any NaN | - | Default NaN |
| - | Any NaN | Default NaN |
| ± 0.0 or denormalized number | \pm infinity | 2.0 |
| \pm infinity | ± 0.0 or denormalized number | 2.0 |

Floating-point square root

The `FPSqrt()` function returns the square root of a floating-point number.

Floating-point reciprocal square root estimate and step

The Advanced SIMD implementation includes instructions that support Newton-Raphson calculation of the reciprocal of the square root of a number.

The VRSQRTE instruction produces the initial estimate of the reciprocal of the square root. It uses the pseudocode functions:

- `FPRSqrtEstimate()`.
- `UnsignedRSqrtEstimate()`. This pseudocode function calls the C function `recip_sqrt_estimate()`.

```
double recip_sqrt_estimate(double a)
{
    int q0, q1, s;
    double r;
    if (a < 0.5) /* range 0.25 <= a < 0.5 */
    {
        q0 = (int)(a * 512.0); /* a in units of 1/512 rounded down */
        r = 1.0 / sqrt(((double)q0 + 0.5) / 512.0); /* reciprocal root r */
    }
    else /* range 0.5 <= a < 1.0 */
    {
        q1 = (int)(a * 256.0); /* a in units of 1/256 rounded down */
        r = 1.0 / sqrt(((double)q1 + 0.5) / 256.0); /* reciprocal root r */
    }
    s = (int)(256.0 * r + 0.5); /* r in units of 1/256 rounded to nearest */
    return (double)s / 256.0;
}
```

Table E1-8 shows the results where input values are out of range.

Table E1-8 VRSQRTE results for out of range inputs

| Number type | Input Vm[i] | Result Vd[i] |
|----------------|--------------------------------------|------------------------|
| Integer | <= 0x3FFFFFFF | 0xFFFFFFFF |
| Floating-point | NaN, -(normalized number), -infinity | Default NaN |
| Floating-point | -0 or -(denormalized number) | -infinity ^a |
| Floating-point | +0 or +(denormalized number) | +infinity ^a |
| Floating-point | +infinity | +0 |

a. FPSCR.DZC is set to 1.

The Newton-Raphson iteration:

$$x_{n+1} = x_n(3 - dx_n^2)/2$$

converges to $(1/\sqrt{d})$ if x_0 is the result of VRSQRTE applied to d .

The VRSQRTE instruction performs a $(3 - \text{op1} \times \text{op2})/2$ calculation and can be used with two multiplications to perform a step of this iteration. The functionality of this instruction is defined by the `FPRsqrtStep()` pseudocode function.

Table E1-9 shows the results where input values are out of range.

Table E1-9 VRSQRTE results for out of range inputs

| Input Vn[i] | Input Vm[i] | Result Vd[i] |
|----------------------------------|----------------------------------|--------------|
| Any NaN | - | Default NaN |
| - | Any NaN | Default NaN |
| ± 0.0 or denormalized number | \pm infinity | 1.5 |
| \pm infinity | ± 0.0 or denormalized number | 1.5 |

`FPRsqrtStep()` calls the `FPHalvedSub()` pseudocode function.

Floating-point conversions

The `FPConvert()` pseudocode function performs conversions between half-precision, single-precision, and double-precision floating-point numbers.

The `FPToFixed()` and `FixedToFP()` functions perform conversions between floating-point numbers and integers or fixed-point numbers.

E1.4 About the AArch32 System register interface

AArch32 state provides a System register encoding space, that is indexed by the parameter set { coproc, opc1, CRn, CRm, opc2 }, and a set of System register access instructions. This encoding space is used for:

- System registers.
- System instructions, for:
 - Cache and branch predictor maintenance.
 - Address translation.
 - TLB maintenance.

In ARMv8, this encoding space uses only the coproc values 0b111x.

———— **Note** —————

The encoding space with coproc values 0b101x is redefined to provide Advanced SIMD and floating-point functionality.

In ARMv8:

- The (coproc==0b1111) encodings provide system control functionality, by providing access to System registers and System instructions. This includes architecture and feature identification, as well as control, status information and configuration support.

The following sections give a general description of these encodings:

- [About the System registers for VMSAv8-32 on page G4-4148.](#)
- [VMSAv8-32 organization of registers in the \(coproc==0b1111\) encoding space on page G4-4175.](#)
- [Functional grouping of VMSAv8-32 System registers on page G4-4193.](#)

These encodings also provide the Performance monitor registers, see [Chapter D5 The Performance Monitors Extension](#).

- The (coproc==0b1110) encodings provide access to additional registers, that support:
 - Debug, see [Chapter G2 AArch32 Self-hosted Debug](#).
 - The Jazelle identification registers, see [Jazelle support on page E1-2299](#).

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses on page G4-4151 gives information more information about permitted accesses to the System registers in AArch32 state.

Most functionality in the (coproc==0b111x) encoding space cannot be accessed by software executing at EL0. This manual clearly identifies those functions that can be accessed at EL0.

For more information:

- About this encoding space, including the naming of the parameters that index the space, see [The AArch32 System register interface on page G1-3877](#).
- About the System interface access instructions, see [System register access instructions on page F1-2387](#).

E1.5 Exceptions

The ARM architecture uses the following terms to describe various types of exceptional condition:

Exceptions In the ARM architecture, an *exception* causes entry to EL1, EL2, or EL3. If the Exception level that is entered is using AArch32, it also causes entry to the PE mode in which the exception must be taken. A software handler for the exception is then executed.

———— **Note** —————

The term *floating-point exception* does not use this meaning of *exception*. This term is described later in this list.

Exceptions include:

- Reset.
- Interrupts.
- Memory system aborts.
- Undefined instructions.
- Supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).
- Debug exceptions.

Most details of exception handling are not visible to application level software, and are described in [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#). In an ARMv8 implementation that includes all the Exception levels, aspects that are visible to application level software are:

- The SVC instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at EL1.
- The SMC instruction causes a Secure Monitor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at EL1 or higher.
- The HVC instruction causes a Hypervisor Call exception, but only if software execution is at EL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at EL1 or higher.
- The BKPT instruction causes a Breakpoint Instruction exception, that is taken as a Prefetch Abort exception. This provides a mechanism for a debugger to insert breakpoints into unprivileged software, or for unprivileged software to make a call into a debugger that is accessible at EL1.
- The WFI (Wait for Interrupt) instruction provides a hint that nothing needs to be done until an interrupt or another WFI wake-up event occurs, see [Wait For Interrupt on page G1-3875](#). This means the hardware might enter a low-power state until the wake-up event occurs.
- The WFE (Wait for Event) instruction provides a hint that nothing needs to be done until either an SEV instruction generates an event, or another WFE wake-up event occurs, see [Wait For Event and Send Event on page G1-3872](#). This means the hardware might enter a low-power state until the wake-up event occurs.

Floating-point exceptions

These relate to exceptional conditions encountered during floating-point arithmetic, such as division by zero or overflow. For more information see:

- [Floating-point exceptions on page E1-2303](#).
- [FPExc, Floating-Point Exception Control register on page G6-4330](#).
- [FPSCR, Floating-Point Status and Control Register on page G6-4335](#).
- ANSI/IEEE Std. 754, *IEEE Standard for Binary Floating-Point Arithmetic*.

Chapter E2

The AArch32 Application Level Memory Model

This chapter gives an application level description of the memory model for software executing in AArch32 state. This means it describes the memory model for execution in EL0 when EL0 is using AArch32 in the following sections:

- [Address space](#) on page E2-2316.
- [Memory type overview](#) on page E2-2317.
- [Caches and memory hierarchy](#) on page E2-2318.
- [Alignment support](#) on page E2-2323.
- [Endian support](#) on page E2-2325.
- [Atomicity in the ARM architecture](#) on page E2-2328.
- [Memory ordering](#) on page E2-2332.
- [Memory types and attributes](#) on page E2-2342.
- [Mismatched memory attributes](#) on page E2-2352.
- [Synchronization and semaphores](#) on page E2-2355

Note

In this chapter, System register names usually link to the description of the register in [Chapter G6 AArch32 System Register Descriptions](#), for example [SCTLR](#).

E2.1 Address space

Address calculations are performed using 32-bit registers. Supervisory software determines the valid address range.

Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo 2^{32} .

The result of an address calculation is UNKNOWN if it overflows or underflows the 32-bit address range A[31:0].

Memory accesses use the `MemA[]`, `MemO[]`, `MemU[]`, and `MemU_unpriv[]` pseudocode functions:

- The `MemA[]` function makes an aligned access of the required type.
- The `MemO[]` function makes an ordered access of the required type.
- The `MemU[]` function makes an unaligned access of the required type
- The `MemU_unpriv[]` function makes an unaligned, unprivileged access of the required type.

Each of these functions calls `Mem_with_type[]` function, that specifies the required access. This calls `AArch32.MemSingle[]`, which performs an atomic, little-endian read of size bytes.

The `AccType` enumeration defines the different access types.

Note

- [Chapter G3 The AArch32 System Level Memory Model](#) and [Chapter G4 The AArch32 Virtual Memory System Architecture](#) include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also reference pseudocode descriptions of these operations.
 - For references to the pseudocode that relates to memory accesses, see [Basic memory access on page G3-4017](#), [Unaligned memory access on page G3-4018](#), and [Aligned memory access on page G3-4018](#).
-

E2.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

- Normal** This is generally used for bulk memory operations, both read-write and read-only operations.
- Device** The ARM architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.
- Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.
- Device memory has additional attributes that have the following effects:
- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See [Gathering](#) on page E2-2348.
 - They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See [Reordering](#) on page E2-2349
 - They indicate whether a write can be acknowledged other than at the end point. See [Early Write Acknowledgement](#) on page E2-2350.
- For more information on Normal memory and Device memory, see [Memory types and attributes](#) on page E2-2342.

Note

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-Ordered memory type. A Note in [Device memory](#) on page E2-2346 describes how these memory types map onto the ARMv8 memory types.

E2.3 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- [Introduction to caches.](#)
- [Memory hierarchy.](#)
- [Implication of caches for the application programmer on page E2-2320.](#)
- [Preloading caches on page E2-2321.](#)

E2.3.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access and take account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

E2.3.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. [Figure E2-1 on page E2-2319](#) shows an example of such a system in an ARMv8-A system that supports virtual addressing.

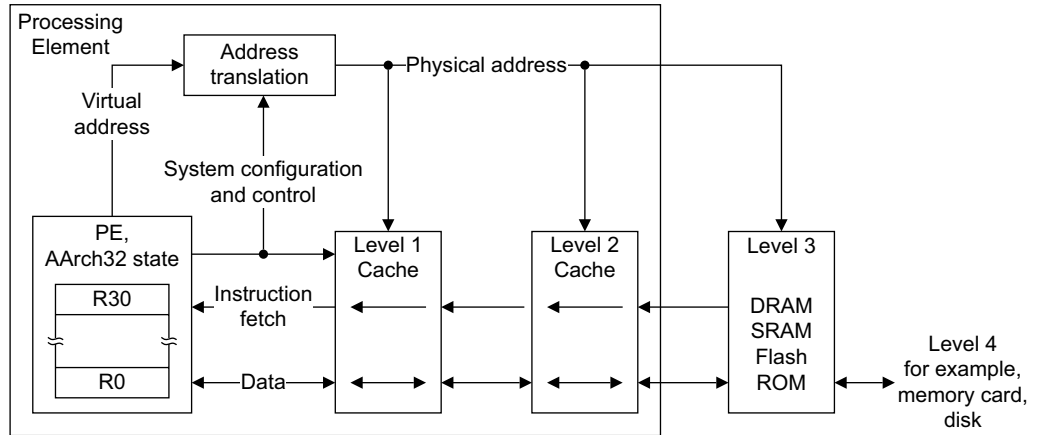

Figure E2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the PE, as shown in [Figure E2-1](#).

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined by two conceptual points:

Point of Unification (PoU)

The point at which the instruction cache, data cache, and translation table walks of a particular PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged. The point of unification might coincide with the point of coherency.

Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

Note

The presence of system caches can affect the definition of the point of coherency as described in [System level caches on page D3-1713](#).

See also [About cache maintenance in ARMv8 on page G3-3995](#).

The Cacheability and Shareability memory attributes

Cacheability and Shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability is defined independently for Inner and Outer Cacheability locations.

Shareability This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability is defined independently for Inner and Outer Shareability domains.

For more information about the Cacheability and Shareability attributes see [Memory types and attributes on page E2-2342](#).

E2.3.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
 - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
 - Not enabling caches in the system.
- By using system calls to functions using cache maintenance instructions that execute at a higher Exception level.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see [Non-shareable Normal memory on page E2-2344](#) and [Shareable, Inner Shareable, and Outer Shareable Normal memory on page E2-2343](#).

———— **Note** —————

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last [Context synchronization event](#) on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using Context synchronization events, DSB memory barriers, and cache maintenance instructions. See [Context synchronization event](#). These can only be accessed from an Exception level that is higher than EL0, and therefore require a system call, see [Exception-generating and exception-handling instructions on page F1-2386](#). The following code sequence can be used for this purpose:

```

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn      ; Clean data cache by MVA to point of unification (PoU)
DSB             ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn     ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn      ; Invalidate branch predictor by MVA to PoU
DSB             ; Ensure completion of the invalidations
ISB             ; Synchronize the fetched instruction stream

```

Note

- For accesses that are Non-cacheable or Write-Through, the clean data cache instruction is not required. For accesses that are Non-cacheable, the invalidate instruction cache is not required, because in AArch32 state these accesses are not permitted to be held in an instruction cache.
 - This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See [Concurrent modification and execution of instructions on page E2-2330](#).
-

E2.3.4 Preloading caches

The ARM architecture provides the memory system hints PLD (Preload Data), PLDW (Preload Data With Intent To Write) and PLI (Preload Instruction) that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous external abort, which is reported using an SError interrupt and taken using an asynchronous Data Abort exception. For more information, see [Data Abort exception on page G1-3859](#).

A PLD, PLDW, or PLI instruction can only cause allocation to software-visible caching structures such caches or TLBs for memory locations that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

A PLD, PLDW, or PLI instruction can access any memory location in Normal memory that can be accessed, according to the permissions defined by the current translation regime or a translation regime for a higher Exception level in the current Security state, by any of:

- Reads.
- Writes.
- Instruction fetches.

Note

In each case, the entire list applies to each of PLD, PLDW, and PLI.

A PLD, PLDW, or PLI instruction is guaranteed not to access any type of Device memory.

A PLI instruction must not perform any access that cannot be performed by a speculative instruction fetch by the processor. Therefore in a VMSA implementation, if all associated MMUs are disabled, a PLI instruction cannot access any memory location that cannot be accessed by instruction fetches.

The pseudocode enumeration [PrefetchHint](#) defines the prefetch hint types.

The [Hint_Prefetch\(\)](#) pseudocode function signals to the memory system that memory accesses of the type hint to or from the specified address are likely to occur in the near future. The memory system might take some action to speed up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level target and non-temporal hint stream.

For more information on PLD, PLI, and PLDW, see:

- [PLD, PLDW \(immediate\)](#) on page F5-2869.
- [PLD \(literal\)](#) on page F5-2871.
- [PLD, PLDW \(register\)](#) on page F5-2873.
- [PLI \(immediate, literal\)](#) on page F5-2875.
- [PLI \(register\)](#) on page F5-2878.

E2.4 Alignment support

This section describes alignment support. It contains the following subsections:

- [Instruction alignment](#).
- [Unaligned data access](#).
- [Cases where unaligned accesses are CONstrained UNPREDICTABLE](#) on page E2-2324.
- [Unaligned data access restrictions](#) on page E2-2324.

E2.4.1 Instruction alignment

A32 instructions are word-aligned.

T32 instructions are halfword-aligned.

E2.4.2 Unaligned data access

An ARMv8 implementation must support unaligned data accesses to Normal memory by some load and store instructions. As [Table E2-1](#) shows, software can control whether a misaligned access to Normal memory by one of these instructions causes an Alignment fault Data Abort exception:

- By setting [SCTLR.A](#), for unaligned accesses from any mode other than Hyp mode.
- By setting [HSCTLR.A](#), for unaligned accesses from Hyp mode.

Table E2-1 Alignment requirements of load/store instructions

| Instructions | Alignment check | Result if check fails when: | |
|--|--------------------------|--|--|
| | | SCTLR.A or HSCTLR.A is 0 | SCTLR.A or HSCTLR.A is 1 |
| LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB | None | - | - |
| LDRH, LDRHT, LDRSH, LDRSHT, STRH, STRHT, TBH | Halfword | Unaligned access | Alignment fault |
| LDREXH, STREXH, LDAH, STLH, LDAEXH, STLEXH | Halfword | Alignment fault | Alignment fault |
| LDR, LDRT, STR, STRT PUSH, encodings T3 and A2 only POP, encodings T3 and A2 only | Word | Unaligned access | Alignment fault |
| LDREX, STREX, LDA, STL, LDAEX, STLEX | Word | Alignment fault | Alignment fault |
| LDREXD, STREXD, LDAEXD, STLEXD | Doubleword | Alignment fault | Alignment fault |
| All forms of LDM and STM, LDRD, RFE, SRS, STRD | Word | Alignment fault | Alignment fault |
| LDC, STC | Word | Alignment fault | Alignment fault |
| VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR | Word | Alignment fault | Alignment fault |
| VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with standard alignment | Element size | Unaligned access | Alignment fault |
| VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :<align> specified ^a | As specified by :<align> | Alignment fault | Alignment fault |

a. Previous versions of this manual used @<align> to specify alignment. Both forms are supported, see [Chapter F6 T32 and A32 Advanced SIMD and floating-point Instruction Descriptions](#) for more information.

Note

Any unaligned access to any type of Device memory generates an Alignment fault, see [Alignment faults on page G4-4117](#).

E2.4.3 Cases where unaligned accesses are CONstrained UNPREDICTABLE

Any load instruction that is not faulted by the alignment restrictions shown in [Table E2-1 on page E2-2323](#) and that loads the PC has CONstrained UNPREDICTABLE behavior if the address it loads from is not word-aligned, see [Loads and Stores to unaligned locations on page K1-5458](#). This overrides any permitted Load/Store behavior shown in [Table E2-1 on page E2-2323](#).

E2.4.4 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see [Atomicity in the ARM architecture on page E2-2328](#).
