
Double-precision scalar variant

Applies when size == 11.

VMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
advsimd = FALSE; add = (op == '0');
case size of
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
advsimd = TRUE; add = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

T2

Single-precision scalar variant

Applies when size == 10.

VMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Double-precision scalar variant

Applies when size == 11.

VMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
advsimd = FALSE; add = (op == '0');
case size of
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding A2, T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
 F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
- <Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                product = FPMu1(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize], StandardFPSCRValue());
                addend = if add then product else FPNeg(product);
                Elem[D[d+r],e,esize] = FPAdd(Elem[D[d+r],e,esize], addend, StandardFPSCRValue());
            // VFP instruction
    else
        case esize of
            when 32
                addend32 = if add then FPMu1(S[n], S[m], FPSCR) else FPNeg(FPMu1(S[n], S[m], FPSCR));
                S[d] = FPAdd(S[d], addend32, FPSCR);
            when 64
                addend64 = if add then FPMu1(D[n], D[m], FPSCR) else FPNeg(FPMu1(D[n], D[m], FPSCR));
                D[d] = FPAdd(D[d], addend64, FPSCR);
  
```

F6.1.106 VMLA (integer)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and adds the products to the corresponding elements of the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

F6.1.110 VMLS (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

———— **Note** ————

ARM recommends that software does not use the VMLS instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

From general-purpose registers variant

Applies when op == 0.

VMOV{<c>}{<q>} <Dm>, <Rt>, <Rt2>

To general-purpose registers variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Dm>

Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(M:Vm);
if t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

From general-purpose registers variant

Applies when op == 0.

VMOV{<c>}{<q>} <Dm>, <Rt>, <Rt2>

To general-purpose registers variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Dm>

Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(M:Vm);  
if t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13  
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers && t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VMOV (between two general-purpose registers and a doubleword floating-point register)* on page K1-5472.

Assembler symbols

| | |
|-------|---|
| <Dm> | Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the "M:Vm" field. |
| <Rt2> | Is the first general-purpose register that <Dm>[63:32] will be transferred to or from, encoded in the "Rt" field. |
| <Rt> | Is the first general-purpose register that <Dm>[31:0] will be transferred to or from, encoded in the "Rt" field. |
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);  
    if to_arm_registers then  
        R[t] = D[m]<31:0>;  
        R[t2] = D[m]<63:32>;  
    else  
        D[m]<31:0> = R[t];  
        D[m]<63:32> = R[t2];
```

F6.1.116 VMOV (immediate)

Copy immediate value to a SIMD&FP register places an immediate constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

| $<Dm>$ | Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field. |

Operation for all encodings

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

F6.1.119 VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars on page F2-2432](#).

Depending on settings in the CPACR, NSACR, HCPTR, and FPFXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDorVFPEEnabled(TRUE, advsimd);
    Elem[D[d],index,esize] = R[t]<esize-1:0>;
```

F6.1.120 VMOV (between general-purpose register and single-precision)

Copy a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in a 32-bit SIMD&FP register to a general-purpose register, or the value held in a general-purpose register to a 32-bit SIMD&FP register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

From general-purpose register variant

Applies when op == 0.

VMOV{<c>}{<q>} <Sn>, <Rt>

To general-purpose register variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Sn>

Decode for all variants of this encoding

```
if size != '10' then UNDEFINED;
to_arm_register = (op == '1'); t = UInt(Rt); n = UInt(Vn:N);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

T1

From general-purpose register variant

Applies when op == 0.

VMOV{<c>}{<q>} <Sn>, <Rt>

To general-purpose register variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Sn>

Decode for all variants of this encoding

```
if size != '10' then UNDEFINED;
to_arm_register = (op == '1'); t = UInt(Rt); n = UInt(Vn:N);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <Rt> Is the general-purpose register that <Sn> will be transferred to or from, encoded in the "Rt" field.
- <Sn> Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the "Vn:N" field.
- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if to_arm_register then
        R[t] = S[n];
    else
        S[n] = R[t];
```

F6.1.121 VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see [Advanced SIMD scalars on page F2-2432](#).

Depending on settings in the CPACR, NSACR, HCPTR, and FPFXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Assembler symbols

| | |
|---------|---|
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | The data type. It must be one of: S8 Encoded as U = 0, opc1<1> = 1. [x] is encoded in opc1<0>, opc2. S16 Encoded as U = 0, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>. U8 Encoded as U = 1, opc1<1> = 1. [x] is encoded in opc1<0>, opc2. U16 Encoded as U = 1, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>. 32 Encoded as U = 0, opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>. omitted Equivalent to 32. |
| <Rt> | The destination general-purpose register. |
| <Dn[x]> | The scalar. For details of how [x] is encoded see the description of <dt>. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if unsigned then
        R[t] = ZeroExtend(Elem[D[n],index,esize], 32);
    else
        R[t] = SignExtend(Elem[D[n],index,esize], 32);
```

F6.1.122 VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

From general-purpose registers variant

Applies when op == 0.

VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>

To general-purpose registers variant

Applies when op == 1.

VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>

Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If to_arm_registers && t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If m == 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

T1

From general-purpose registers variant

Applies when `op == 0`.

`VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>`

To general-purpose registers variant

Applies when `op == 1`.

`VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>`

Decode for all variants of this encoding

```
to_arm_registers = (op == '1'); t = UInt(Rt); t2 = UInt(Rt2); m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers && t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

If `m == 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VMOV (between two general-purpose registers and two single-precision registers)* on page K1-5472.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>1],e,2*esize] = result<2*esize-1:0>;
```

F6.1.124 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-3881*.

This instruction is used by the pseudo-instructions VRSHRN (zero) and VSHRN (zero). The pseudo-instruction is never the preferred disassembly.

    for e = 0 to elements-1
        Elem[D[d],e,size] = Elem[Qin[m>1],e,2*size]<size-1:0>;
  
```

F6.1.125 VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the **FPSCR**, a form of the instruction transfers the **FPSCR**.{N, Z, C, V} condition flags to the **APSR**.{N, Z, C, V} condition flags.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

When these settings permit the execution of floating-point and Advanced SIMD instructions, if the specified floating-point System register is not the **FPSCR**, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when **HCR.TID0** is set to 1, any VMRS access to **FPSID** from a Non-secure EL1 mode that would be permitted if **HCR.TID0** was set to 0 generates a Hyp Trap exception. For more information, see [ID group 0, Primary device identification registers on page G1-3902](#).

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|-----|----|----|----|----|----|-----|-----|-----|---|-----|-----|-----|-----|---|---|---|

A1 variant

VMRS{<c>}{<q>} <Rt>, <spec_reg>

Decode for this encoding

```
t = UInt(Rt);
if !(reg IN {'000x', '0101', '011x', '1000'}) then UNPREDICTABLE;
if t == 15 && reg != '0001' then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If !(reg IN {'000x', '0101', '011x', '1000'}), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the **APSR**.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |

        when '1000' R[t] = FPEXC;
        otherwise Unreachable(); // Dealt with above or in encoding-specific pseudocode
```

F6.1.126 VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

When these settings permit the execution of floating-point and Advanced SIMD instructions:

- If the specified floating-point System register is not the FPSCR, the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the FPEXC and the instruction is executed in a mode other than User mode the instruction is ignored.

A1

A1 variant

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
t = UInt(Rt);
if reg != '000x' && reg != '1000' then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If reg != '000x' && reg != '1000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

T1

T1 variant

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
t = UInt(Rt);
if reg != '000x' && reg != '1000' then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `reg != '000x' && reg != '1000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<spec_reg> Is the destination Advanced SIMD and floating-point System register, encoded in the "reg" field. It can have the following values:

FPSID when reg = 0000

FPSCR when reg = 0001

FPEXC when reg = 1000

The following encodings are UNPREDICTABLE:

- reg = 001x.
- reg = 01xx.
- reg = 1001.
- reg = 101x.
- reg = 11xx.

<Rt> Is the general-purpose source register, encoded in the "Rt" field.

Operation for all encodings

```

if ConditionPassed() then

```

F6.1.127 VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding A2, T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
 F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
- <Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                Elem[D[d+r],e,esize] = FPMu1(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize],
StandardFPSCRValue());
    else // VFP instruction
        case esize of
            when 32
                S[d] = FPMu1(S[n], S[m], FPSCR);
            when 64
                D[d] = FPMu1(D[n], D[m], FPSCR);
  
```

F6.1.128 VMUL (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors.

For information about multiplying polynomials see *Polynomial arithmetic over {0, 1}* on page A1-45.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
    
```

Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2454](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2541](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
- For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <dt> Is the data type for the scalar and the elements of the operand vector, encoded in the "U:size" field. It can have the following values:
- | | |
|-----|-----------------------|
| S16 | when U = 0, size = 01 |
| S32 | when U = 0, size = 10 |
| U16 | when U = 1, size = 01 |
| U32 | when U = 1, size = 10 |
- The following encodings are reserved:
- U = 0, size = 00.
 - U = 0, size = 11.
 - U = 1, size = 00.
 - U = 1, size = 11.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.
- <index> Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  op2 = Elem[Din[m],index,size]; op2val = Int(op2, unsigned);
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[Din[n+r],e,size]; op1val = Int(op1, unsigned);
      if floating_point then
        Elem[D[d+r],e,size] = FPMul(op1, op2, StandardFPSCRValue());
      else
        if long_destination then
          Elem[Q[d>>1],e,2*size] = (op1val*op2val)<2*size-1:0>;
        else
          Elem[D[d+r],e,size] = (op1val*op2val)<size-1:0>;
  
```

F6.1.132 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding A2, T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

- <dt> Is the data type for the elements of the vectors, encoded in the "F:size" field. It can have the following values:
- S8 when F = 0, size = 00
 - S16 when F = 0, size = 01
 - S32 when F = 0, size = 10
 - F32 when F = 1, size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                if floating_point then
                    Elem[D[d+r],e,esize] = FPNeg(Elem[D[m+r],e,esize]);
                else
                    result = -SInt(Elem[D[m+r],e,esize]);
                    Elem[D[d+r],e,esize] = result<esize-1:0>;
    else // VFP instruction
        case esize of
            when 32 S[d] = FPNeg(S[m]);
            when 64 D[d] = FPNeg(D[m]);
    
```

F6.1.135 VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

———— **Note** —————

ARM recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

VNMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Double-precision scalar variant

Applies when size == 11.

VNMLA{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size != '1x' then UNDEFINED;
type = if op == '1' then VFPNegMul_VNMLA else VFPNegMul_VNMLS;

                when VFPNegMul_VNMUL D[d] = FPNeg(product64);

```

F6.1.137 VNMUL

Vector Negate Multiply multiplies together two floating-point register values, and writes the negation of the result to the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

F6.1.138 VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector

This instruction is a pseudo-instruction of the [VORR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|-------|----|---|---|---|------|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

is equivalent to

VORR{<c>}{<q>}.<dt> <Dd>, #~<imm>

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

VORN{<c>}{<q>}.<dt> {<Qd>}, <Qd>, #<imm>

is equivalent to

VORR{<c>}{<q>}.<dt> <Qd>, #~<imm>

and is never the preferred disassembly.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> The data type used for <imm>. It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <imm> Is a constant of the type specified by <dt> that is replicated to fill the destination register. For details of the range of constants available and the encoding of <dt> and <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2423](#).

Operation for all encodings

The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

F6.1.139 VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
  
```

F6.1.142 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows an example of the operation of VPADAL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<dt> Is the data type for the elements of the vectors, encoded in the "op:size" field. It can have the following values:

| | |
|-----|------------------------|
| S8 | when op = 0, size = 00 |
| S16 | when op = 0, size = 01 |
| S32 | when op = 0, size = 10 |
| U8 | when op = 1, size = 00 |
| U16 | when op = 1, size = 01 |
| U32 | when op = 1, size = 10 |

The following encodings are reserved:

- op = 0, size = 11.
- op = 1, size = 11.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();  CheckAdvSIMDEnabled();
  h = elements DIV 2;

  for r = 0 to regs-1
    for e = 0 to h-1
      op1 = Elem[D[m+r],2*e,esize];  op2 = Elem[D[m+r],2*e+1,esize];
      result = Int(op1, unsigned) + Int(op2, unsigned);
      Elem[D[d+r],e,2*esize] = Elem[D[d+r],e,2*esize] + result;
```

F6.1.143 VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are 32-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

A1 variant

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if Q == '1' then UNDEFINED;
if sz == '1' then UNDEFINED;
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

T1

T1 variant

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if Q == '1' then UNDEFINED;
if sz == '1' then UNDEFINED;
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
F32 when sz = 0

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize] = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize],
StandardFPSCRValue());
        Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize],
StandardFPSCRValue());

    D[d] = dest;
```

F6.1.144 VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows an example of the operation of VPADD doubleword operation for data type I16.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

A1 variant

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    
```

T1

T1 variant

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```

if Q == '1' then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
 F32 when sz = 0
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        op1 = Elem[D[n],2*e,esize]; op2 = Elem[D[n],2*e+1,esize];
        Elem[dest,e,esize] = if maximum then FMax(op1,op2,StandardFPSCRValue()) else
FMin(op1,op2,StandardFPSCRValue());
        op1 = Elem[D[m],2*e,esize]; op2 = Elem[D[m],2*e+1,esize];
        Elem[dest,e+h,esize] = if maximum then FMax(op1,op2,StandardFPSCRValue()) else
FMin(op1,op2,StandardFPSCRValue());

    D[d] = dest;
```

F6.1.149 VPMIN (integer)

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

A1 variant

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if size == '11' || Q == '1' then UNDEFINED;
maximum = (op == '0'); unsigned = (U == '1');
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

T1

T1 variant

VPMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if size == '11' || Q == '1' then UNDEFINED;
maximum = (op == '0'); unsigned = (U == '1');
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

Assembler symbols

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:

- S8 when U = 0, size = 00
- S16 when U = 0, size = 01
- S32 when U = 0, size = 10
- U8 when U = 1, size = 00

- U16 when U = 1, size = 01
U32 when U = 1, size = 10
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        op1 = Int(Elem[D[n],2*e,esize], unsigned);
        op2 = Int(Elem[D[n],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e,esize] = result<esize-1:0>;
        op1 = Int(Elem[D[m],2*e,esize], unsigned);
        op2 = Int(Elem[D[m],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e+h,esize] = result<esize-1:0>;

D[d] = dest;
```

F6.1.150 VPOP

Pop SIMD&FP registers from Stack loads multiple consecutive Advanced SIMD and floating-point register file registers from the stack

This instruction is an alias of the [VLDM](#), [VLDMDB](#), [VLDMIA](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VLDM](#), [VLDMDB](#), [VLDMIA](#).
- The description of [VLDM](#), [VLDMDB](#), [VLDMIA](#) gives the operational pseudocode for this instruction.

A1

Increment After variant

VPOP{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

A2

Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

T1

Increment After variant

VPOP{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

T2

Increment After variant

VPOP{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VLDM{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Operation for all encodings

The description of [VLDM](#), [VLDMDB](#), [VLDMIA](#) gives the operational pseudocode for this instruction.

F6.1.151 VPUSH

Push SIMD&FP registers to Stack stores multiple consecutive registers from the Advanced SIMD and floating-point register file to the stack

This instruction is an alias of the **VSTM**, **VSTMDB**, **VSTMIA** instruction. This means that:

- The encodings in this description are named to match the encodings of **VSTM**, **VSTMDB**, **VSTMIA**.
- The description of **VSTM**, **VSTMDB**, **VSTMIA** gives the operational pseudocode for this instruction.

A1

Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

A2

Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

T1

Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <dreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <dreglist>

and is always the preferred disassembly.

T2

Decrement Before variant

VPUSH{<c>}{<q>}{.<size>} <sreglist>

is equivalent to

VSTMDB{<c>}{<q>}{.<size>} SP!, <sreglist>

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<size> An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Operation for all encodings

The description of [VSTM](#), [VSTMDB](#), [VSTMIA](#) gives the operational pseudocode for this instruction.

F6.1.152 VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

            if sat then FPSR.QC = '1';
  
```

F6.1.154 VQDMLAL

Vector Saturating Doubling Multiply Accumulate Long multiplies corresponding elements in two doubleword vectors, doubles the products, and accumulates the results into the elements of a quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see *Advanced SIMD scalars* on page F2-2432.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode description of saturation* on page E1-2291.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

A1 variant

VQDMLAL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
```

Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2454](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2541](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1 and A2: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 S16 when size = 01
 S32 when size = 10
 The following encodings are reserved:
- size = 00.
 - size = 11.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.

<index> Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
    if sat1 || sat2 then FPSR.QC = '1';
```

F6.1.155 VQDMLSL

Vector Saturating Doubling Multiply Subtract Long multiplies corresponding elements in two doubleword vectors, subtracts double the products from corresponding elements of a quadword vector, and places the results in the same quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#) on page F2-2432.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode description of saturation](#) on page E1-2291.

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#) on page G1-3881.

A1

A1 variant

VQDMLSL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```

if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
add = (op == '0');
scalar_form = FALSE; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
esize = 8 << UInt(size); elements = 64 DIV esize;
    
```

A2

A2 variant

VQDMLSL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```

if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
add = (op == '0');
scalar_form = TRUE; d = UInt(D:Vd); n = UInt(N:Vn);
if size == '01' then esize = 16; elements = 4; m = UInt(Vm<2:0>); index = UInt(M:Vm<3>);
if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
    
```

T1

T1 variant

VQDMLSL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
add = (op == '0');
scalar_form = FALSE; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
esize = 8 << UInt(size); elements = 64 DIV esize;
```

T2

T2 variant

VQDMLSL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]

Decode for this encoding

```
if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
add = (op == '0');
scalar_form = TRUE; d = UInt(D:Vd); n = UInt(N:Vn);
if size == '01' then esize = 16; elements = 4; m = UInt(Vm<2:0>); index = UInt(M:Vm<3>);
if size == '10' then esize = 32; elements = 2; m = UInt(Vm); index = UInt(M);
```

Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2454](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2541](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1 and A2: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 S16 when size = 01
 S32 when size = 10
 The following encodings are reserved:
 - size = 00.
 - size = 11.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> For encoding A1 and T1: is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

For encoding A2 and T2: is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16, otherwise the "Vm" field.

<index> Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16, otherwise in range 0 to 1, encoded in the "M" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
        if sat1 || sat2 then FPSR.QC = '1';
```

F6.1.156 VQDMULH

Vector Saturating Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are truncated, for rounded results see [VQRDMULH](#).

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#) on page F2-2432.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation](#) on page E1-2291.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#) on page G1-3881.

        (product, sat) = SignedSatQ(2*op1*op2, 2*esize);
        Elem[Q[d>>1],e,2*esize] = product;
        if sat then FPSR.QC = '1';
```

F6.1.158 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, **FPSCR.QC**, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instructions **VQRSHRN (zero)**, **VQRSHRUN (zero)**, **VQSHRN (zero)**, and **VQSHRUN (zero)**. The pseudo-instruction is never the preferred disassembly.

|-----|----------------|
| S16 | when size = 00 |
| S32 | when size = 01 |
| S64 | when size = 10 |
- The encoding size = 11 is reserved.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (Elem[D[d],e,esize], sat) = SatQ(operand, esize, dest_unsigned);
        if sat then FPSR.QC = '1';
```

F6.1.159 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = -SInt(Elem[D[m+r],e,esize]);
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSR.QC = '1';
```

F6.1.160 VQRDMULH

Vector Saturating Rounding Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are rounded. For truncated results see [VQDMULH](#).

The second operand can be a scalar instead of a vector. For more information about scalars see [Advanced SIMD scalars](#) on page F2-2432.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation](#) on page E1-2291.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#) on page G1-3881.

Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2454](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2541](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1 and A2: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 S16 when size = 01
 S32 when size = 10
 For encoding A2 and T2: is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 S16 when size = 01
 S32 when size = 10
 The following encodings are reserved:
- size = 00.
 - size = 11.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm[x]> The scalar for either a quadword or a doubleword scalar operation. If <dt> is S16, Dm is restricted to D0-D7. If <dt> is S32, Dm is restricted to D0-D15.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = SInt(Elem[D[n+r],e,esize]);
            if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
            (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
  
```

F6.1.161 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see [VQSHL \(register\)](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

| S64 | when op<0> = 0, size = 10 |
| U16 | when op<0> = 1, size = 00 |

U32 when $op<0> = 1$, size = 01

U64 when $op<0> = 1$, size = 10

The following encodings are reserved:

- $op<0> = 0$, size = 11.
- $op<0> = 1$, size = 11.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

F6.1.163 VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see [VQSHL \(register\)](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:

S16 when size = 00

S32 when size = 01

S64 when size = 10

The encoding size = 11 is reserved.

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

F6.1.165 VQSHL, VQSHLU (immediate)

Vector Saturating Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in a second vector.

The operand elements must all be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are the same size as the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            operand = Int(Elem[D[m+r],e,esize], src_unsigned);
            (result, sat) = SatQ(operand << shift_amount, esize, dest_unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSR.QC = '1';
```

F6.1.166 VQSHL (register)

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see [VQRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

op

Signed result variant

VQSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0

is equivalent to

VQMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<dt> Is the data type for the elements of the operand, encoded in the "op<0>:size" field. It can have the following values:

| | |
|-----|---------------------------|
| S16 | when op<0> = 0, size = 00 |
| S32 | when op<0> = 0, size = 01 |
| S64 | when op<0> = 0, size = 10 |
| U16 | when op<0> = 1, size = 00 |

U32 when $op<0> = 1$, size = 01

U64 when $op<0> = 1$, size = 10

The following encodings are reserved:

- $op<0> = 0$, size = 11.
- $op<0> = 1$, size = 11.

$<Dd>$ Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

$<Qm>$ Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as $<Qm> * 2$.

Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

F6.1.168 VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see [VQRSHRN, VQRSHRUN](#).

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, [FPSCR.QC](#), is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <type> For the signed result variant: is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:

| | |
|---|------------|
| S | when U = 0 |
| U | when U = 1 |

 For the unsigned result variant: is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:

| | |
|---|------------|
| S | when U = 1 |
|---|------------|
- <size> Is the data size for the elements of the vectors, encoded in the "imm6<5:3>" field. It can have the following values:

| | |
|----|----------------------|
| 16 | when imm6<5:3> = 001 |
| 32 | when imm6<5:3> = 01x |
| 64 | when imm6<5:3> = 1xx |
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for e = 0 to elements-1
    operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
  
```

```
(result, sat) = SatQ(operand >> shift_amount, esize, dest_unsigned);  
Elem[D[d],e,esize] = result;  
if sat then FPSR.QC = '1';
```

F6.1.169 VQSHRUN (zero)

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the unsigned truncated results in a doubleword vector

This instruction is a pseudo-instruction of the [VQMOVN](#), [VQMOVUN](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VQMOVN](#), [VQMOVUN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:

S16 when size = 00

S32 when size = 01

S64 when size = 10

The encoding size = 11 is reserved.

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

The description of [VQMOVN](#), [VQMOVUN](#) gives the operational pseudocode for this instruction.

F6.1.170 VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, `FPSCR.QC`, is set if saturation occurs. For details see [Pseudocode description of saturation on page E1-2291](#).

Depending on settings in the `CPACR`, `NSACR`, and `HCPTR` registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

F6.1.173 VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step on page E1-2308](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see [Floating-point reciprocal estimate and step on page E1-2308](#).

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();  
    for r = 0 to regs-1  
        for e = 0 to elements-1  
            Elem[D[d+r],e,esize] = FPRecipStep(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize]);
```

F6.1.174 VREV16

Vector Reverse in halfwords reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

The following figure shows an example of the operation of VREV16 doubleword operation.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

F6.1.178 VRINTA (Advanced SIMD)

Vector Round floating-point to integer towards Nearest with Ties to Away rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;  
if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

Related encodings: See [Advanced SIMD two registers misc on page F3-2455](#) for the T32 instruction set, or [Advanced SIMD two registers misc on page F4-2542](#) for the A32 instruction set.

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
F32 when size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();  
for r = 0 to regs-1  
  for e = 0 to elements-1  
    op1 = Elem[D[m+r],e,esize];  
    result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);  
    Elem[D[d+r],e,esize] = result;
```

F6.1.179 VRINTA (floating-point)

Round floating-point to integer to Nearest with Ties to Away rounds a floating-point value to an integral floating-point value of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A1

```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
F32 when size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
  for e = 0 to elements-1
    op1 = Elem[D[m+r],e,esize];
    result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
    Elem[D[d+r],e,esize] = result;
```

F6.1.188 VRINTX (floating-point)

Round floating-point to integer inexact rounds a floating-point value to an integral floating-point value of the same size, using the rounding mode specified in the FPSCR, and raises an Inexact exception when the result value is not numerically equal to the input value. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

A1

Single-precision scalar variant

Applies when size == 10.

VRINTX{<c>}{<q>}.F32 <Sd>, <Sm>

Double-precision scalar variant

Applies when size == 11.

VRINTX{<c>}{<q>}.F64 <Dd>, <Dm>

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
exact = TRUE;
case size of
    when '10' esize = 32; d = UInt(Vd:D); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);
    
```

    when '11' esize = 64; d = UInt(D:Vd); m = UInt(M:Vm);
    
```

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
case esize of
    when 32
        S[d] = FPRoundInt(S[m], FPSCR, rounding, exact);
    when 64
        D[d] = FPRoundInt(D[m], FPSCR, rounding, exact);
```

F6.1.191 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <type> Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:
 - S when U = 0
 - U when U = 1
- <size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
 - 8 when L = 0, imm6<5:3> = 001
 - 16 when L = 0, imm6<5:3> = 01x
 - 32 when L = 0, imm6<5:3> = 1xx
 - 64 when L = 1, imm6<5:3> = xxx
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- <imm> Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  round_const = 1 << (shift_amount - 1);
  for r = 0 to regs-1
    for e = 0 to elements-1
      result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
      Elem[D[d+r],e,esize] = result<esize-1:0>;
  
```

F6.1.193 VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another

This instruction is a pseudo-instruction of the [VORR \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0

is equivalent to

VORR{<c>}{<q>}{.dt} <Dd>, <Dm>, <Dm>

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

$\text{VRSHR}\{\langle c \rangle\}\{\langle q \rangle\}.\langle dt \rangle \langle Qd \rangle, \langle Qm \rangle, \#0$

is equivalent to

$\text{VORR}\{\langle c \rangle\}\{\langle q \rangle\}\{\langle dt \rangle\} \langle Qd \rangle, \langle Qm \rangle, \langle Qm \rangle$

and is never the preferred disassembly.

Assembler symbols

- $\langle c \rangle$ For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- $\langle q \rangle$ See [Standard assembler syntax fields on page F2-2406](#).
- $\langle dt \rangle$ Is the data type for the elements of the vectors, and must be one of: S8, S16, S32, S64, U8, U16, U32 or U64.
- $\langle Qd \rangle$ Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $\langle Qd \rangle * 2$.
- $\langle Qm \rangle$ Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as $\langle Qm \rangle * 2$.
- $\langle Dd \rangle$ Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- $\langle Dm \rangle$ Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

Operation for all encodings

The description of [VORR \(register\)](#) gives the operational pseudocode for this instruction.

F6.1.194 VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see [VSHRN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see *Standard assembler syntax fields* on page F2-2406. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <size> Is the data size for the elements of the vectors, encoded in the "imm6<5:3>" field. It can have the following values:
16 when imm6<5:3> = 001
32 when imm6<5:3> = 01x
64 when imm6<5:3> = 1xx
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount-1);
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m]>>1],e,2*esize) + round_const, shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

F6.1.195 VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector

This instruction is a pseudo-instruction of the **VMOVN** instruction. This means that:

- The encodings in this description are named to match the encodings of **VMOVN**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **VMOVN** gives the operational pseudocode for this instruction.

and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see *Standard assembler syntax fields* on page F2-2406. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields* on page F2-2406.

<q> See *Standard assembler syntax fields* on page F2-2406.

<dt> Is the data type for the elements of the operand, encoded in the "size" field. It can have the following values:

I16 when size = 00

I32 when size = 01

I64 when size = 10

The encoding size = 11 is reserved.

- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

The description of [VMOVN](#) gives the operational pseudocode for this instruction.

F6.1.196 VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be 32-bit floating-point numbers, or 32-bit unsigned integers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step on page E1-2308](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see [Floating-point reciprocal estimate and step on page E1-2308](#).

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        Elem[D[d+r],e,esize] = FPRsqrtEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);
  
```

F6.1.197 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

For details of the operation performed by this instruction see [Floating-point reciprocal estimate and step on page E1-2308](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <type> Is the data type for the elements of the vectors, encoded in the "U" field. It can have the following values:
 - S when U = 0
 - U when U = 1
- <size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:
 - 8 when L = 0, imm6<5:3> = 001
 - 16 when L = 0, imm6<5:3> = 01x
 - 32 when L = 0, imm6<5:3> = 1xx
 - 64 when L = 1, imm6<5:3> = xxx
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- <imm> Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
    
```

F6.1.199 VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see [VSUBHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:

| | |
|----|-----------------------------|
| 8 | when L = 0, imm6<5:3> = 001 |
| 16 | when L = 0, imm6<5:3> = 01x |
| 32 | when L = 0, imm6<5:3> = 1xx |
| 64 | when L = 1, imm6<5:3> = xxx |
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- <imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
  
```

F6.1.202 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see [VRSHL](#).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

F6.1.203 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1 and A2: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <type> The data type for the elements of the operand. It must be one of:
 - S Signed. In encoding T1/A1, encoded as U = 0.
 - U Unsigned. In encoding T1/A1, encoded as U = 1.
 - I Untyped integer, Available only in encoding T2/A2.

<size> The data size for the elements of the operand. The following table shows the permitted values and their encodings:

| <size> | Encoding T1/A1 | Encoding T2/A2 |
|--------|------------------------------|------------------------|
| 8 | Encoded as imm6<5:3> = 0b001 | Encoded as size = 0b00 |
| 16 | Encoded as imm6<5:4> = 0b01 | Encoded as size = 0b01 |
| 32 | Encoded as imm6<5> = 1 | Encoded as size = 0b10 |

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> The immediate value. <imm> must lie in the range 1 to <size>, and:

- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
 - If <size> == 8, <imm> is encoded in imm6<2:0>.
 - If <size> == 16, <imm> is encoded in imm6<3:0>.
 - If <size> == 32, <imm> is encoded in imm6<4:0>.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for e = 0 to elements-1
    result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
    Elem[Q[d>1],e,2*esize] = result<2*esize-1:0>;
  
```

F6.1.204 VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see [VRSHR](#).

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Notes for all encodings

Related encodings: See [Advanced SIMD one register and modified immediate on page F3-2460](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate on page F4-2547](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size for the elements of the vectors, encoded in the "L:imm6<5:3>" field. It can have the following values:

| | |
|----|-----------------------------|
| 8 | when L = 0, imm6<5:3> = 001 |
| 16 | when L = 0, imm6<5:3> = 01x |
| 32 | when L = 0, imm6<5:3> = 1xx |
| 64 | when L = 1, imm6<5:3> = xxx |
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.
- <imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  mask = LSL(Ones(esize), shift_amount);
  for r = 0 to regs-1
    for e = 0 to elements-1
      shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
      Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;

```

F6.1.209 VSQRT

Square Root calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

VSQRT{<c>}{<q>}.F32 <Sd>, <Sm>

Double-precision scalar variant

Applies when size == 11.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 - 8 when size = 00
 - 16 when size = 01
 - 32 when size = 10
- <list> Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
 - <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
 - <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
 - <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and the encoding depends on <size>:

| | |
|--------------|---|
| <size> == 8 | Encoded in the "index_align<0>" field as 0. |
| <size> == 16 | Encoded in the "index_align<1:0>" field as 0b00. |
| <size> == 32 | Encoded in the "index_align<2:0>" field as 0b000. |

Whenever <align> is present, the permitted values and encoding depend on <size>:

| | |
|--------------|--|
| <size> == 16 | <align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01. |
| <size> == 32 | <align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011. |

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,ebytes] = Elem[D[d],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

F6.1.213 VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

Offset variant

Applies when Rm == 1111.

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Post-indexed variant

Applies when Rm == 1101.

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Post-indexed variant

Applies when Rm != 11x1.

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

case type of
  when '0111'
    regs = 1; if align<1> == '1' then UNDEFINED;
  when '1010'
    regs = 2; if align == '11' then UNDEFINED;
  when '0110'
    regs = 3; if align<1> == '1' then UNDEFINED;
  when '0010'
    regs = 4;
  otherwise
    SEE "Related encodings";
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Offset variant

Applies when Rm == 1111.

VST1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Post-indexed variant

wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST1 (multiple single elements)* on page K1-5472.

Related encodings: See *Advanced SIMD element or structure Load/Store* on page F3-2479 for the T32 instruction set, or *Advanced SIMD element or structure Load/Store* on page F4-2553 for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
- | | |
|----|----------------|
| 8 | when size = 00 |
| 16 | when size = 01 |
| 32 | when size = 10 |
| 64 | when size = 11 |
- <list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
- { <Dd> }
 Encoded in the "type" field as 0b0111.
 - { <Dd>, <Dd+1> }
 Encoded in the "type" field as 0b1010.
 - { <Dd>, <Dd+1>, <Dd+2> }
 Encoded in the "type" field as 0b0110.
 - { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
 Encoded in the "type" field as 0b0010.
- The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are:
- | | |
|-----|---|
| 64 | 64-bit alignment, encoded in the "align" field as 0b01. |
| 128 | 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers. |
| 256 | 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers. |
- : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if ebytes != 8 then
                MemU[address,ebytes] = Elem[D[d+r],e];

if n == 15 || d2 > 31 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST2 (single 2-element structure from one lane)* on page K1-5473.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
- <list> Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of:
 { <Dd>[<index>], <Dd+1>[<index>] }
 Single-spaced registers, encoded as "spacing" = 0.
 { <Dd>[<index>], <Dd+2>[<index>] }
 Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
 The encoding of "spacing" depends on <size>:
 <size> == 16 "spacing" is encoded in the "index_align<1>" field.
 <size> == 32 "spacing" is encoded in the "index_align<2>" field.
 The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
 <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
 <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
 <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and the encoding depends on <size>:
 <size> == 8 Encoded in the "index_align<0>" field as 0.
 <size> == 16 Encoded in the "index_align<0>" field as 0.
 <size> == 32 Encoded in the "index_align<1:0>" field as 0b00.
 Whenever <align> is present, the permitted values and encoding depend on <size>:
 <size> == 8 <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
 <size> == 16 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
 <size> == 32 <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

F6.1.215 VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2388](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

| 128 | 128-bit alignment, encoded in the "align" field as 0b10. |
| 256 | 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers. |
- : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            MemU[address, ebytes] = Elem[D[d+r], e];
            MemU[address+ebytes, ebytes] = Elem[D[d2+r], e];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*regs;
  
```

F6.1.216 VST3 (single 3-element structure from one lane)

Store single 3-element structure from one lane of three registers stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

Offset variant

Applies when Rm == 1111.

VST3{<c>}{<q>}.<size> <list>, [<Rn>]

Post-indexed variant

Applies when Rm == 1101.

VST3{<c>}{<q>}.<size> <list>, [<Rn>]!

Post-indexed variant

Applies when Rm != 11x1.

VST3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```

if size == '11' then UNDEFINED;
case size of
  when '00'
    if index_align<0> != '0' then UNDEFINED;
    ebytes = 1; index = UInt(index_align<3:1>); inc = 1;
  when '01'
    if index_align<0> != '0' then UNDEFINED;
    ebytes = 2; index = UInt(index_align<3:2>);
    inc = if index_align<1> == '0' then 1 else 2;
  when '10'
    if index_align<1:0> != '00' then UNDEFINED;
    ebytes = 4; index = UInt(index_align<3>);
    inc = if index_align<2> == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Offset variant

Applies when Rm == 1111.

VST3{<c>}{<q>}.<size> <list>, [<Rn>]

Post-indexed variant

Applies when Rm == 1101.

VST3{<c>}{<q>}.<size> <list>, [<Rn>]!

Post-indexed variant

Applies when Rm != 11x1.

VST3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```

if size == '11' then UNDEFINED;
case size of
  when '00'
    if index_align<0> != '0' then UNDEFINED;
    ebytes = 1; index = UInt(index_align<3:1>); inc = 1;
  when '01'
    if index_align<0> != '0' then UNDEFINED;
    ebytes = 2; index = UInt(index_align<3:2>);
    inc = if index_align<1> == '0' then 1 else 2;
  when '10'
    if index_align<1:0> != '00' then UNDEFINED;
    ebytes = 4; index = UInt(index_align<3>);
    inc = if index_align<2> == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST3 (single 3-element structure from one lane)* on page K1-5473.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
- | | |
|----|----------------|
| 8 | when size = 00 |
| 16 | when size = 01 |
| 32 | when size = 10 |
- <list> Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of:
- { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] }
 Single-spaced registers, encoded as "spacing" = 0.
- { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] }
 Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
- The encoding of "spacing" depends on <size>:
- | | |
|--------------|--|
| <size> == 8 | "spacing" is encoded in the "index_align<0>" field. |
| <size> == 16 | "spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0. |
| <size> == 32 | "spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00. |
- The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
- | | |
|--------------|--|
| <size> == 8 | <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. |
| <size> == 16 | <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. |
| <size> == 32 | <index> is 0 or 1, encoded in the "index_align<3>" field. |
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Alignment

Standard alignment rules apply, see [Alignment support on page B2-76](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    MemU[address, ebytes] = E1em[D[d], index];
    MemU[address+ebytes, ebytes] = E1em[D[d2], index];
    MemU[address+2*ebytes, ebytes] = E1em[D[d3], index];
    if wback then
        if register_index then
  
```

```
R[n] = R[n] + R[m];  
else  
R[n] = R[n] + 3*bytes;
```

F6.1.217 VST3 (multiple 3-element structures)

Store multiple 3-element structures from three registers stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2388](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST3 \(multiple 3-element structures\)](#) on page K1-5473.

Related encodings: See [Advanced SIMD element or structure Load/Store on page F3-2479](#) for the T32 instruction set, or [Advanced SIMD element or structure Load/Store on page F4-2553](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
 The encoding size = 11 is reserved.
- <list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
 { <Dd>, <Dd+1>, <Dd+2> }
 Single-spaced registers, encoded in the "type" field as 0b0100.
 { <Dd>, <Dd+2>, <Dd+4> }
 Double-spaced registers, encoded in the "type" field as 0b0101.
 The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "align" field as 0b00. Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = E1em[D[d], e];
        MemU[address+ebytes, ebytes] = E1em[D[d2],e];
        MemU[address+2*ebytes,ebytes] = E1em[D[d3],e];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;
  
```

F6.1.218 VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

when '10'
    if index_align<1:0> == '11' then UNDEFINED;
    ebytes = 4; index = UInt(index_align<3>);
    inc = if index_align<2> == '0' then 1 else 2;
    alignment = if index_align<1:0> == '00' then 1 else 4 << UInt(index_align<1:0>);
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VST4 (single 4-element structure from one lane)* on page K1-5473.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
- <list> Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of:
 { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] }
 Single-spaced registers, encoded as "spacing" = 0.
 { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }
 Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
 The encoding of "spacing" depends on <size>:
 <size> == 16 "spacing" is encoded in the "index_align<1>" field.
 <size> == 32 "spacing" is encoded in the "index_align<2>" field.
 The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
 <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
 <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
 <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and the encoding depends on <size>:
 <size> == 8 Encoded in the "index_align<0>" field as 0.
 <size> == 16 Encoded in the "index_align<0>" field as 0.
 <size> == 32 Encoded in the "index_align<1:0>" field as 0b00.
 Whenever <align> is present, the permitted values and encoding depend on <size>:
 <size> == 8 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
 <size> == 16 <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.
 <size> == 32 <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address, ebytes] = Elem[D[d], index];
    MemU[address+ebytes, ebytes] = Elem[D[d2], index];
    MemU[address+2*ebytes, ebytes] = Elem[D[d3], index];
    MemU[address+3*ebytes, ebytes] = Elem[D[d4], index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

F6.1.219 VST4 (multiple 4-element structures)

Store multiple 4-element structures from four registers stores multiple 4-element structures to memory from four registers, with interleaving. For more information, see [Element and structure load/store instructions on page F1-2388](#). Every element of each register is saved. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Post-indexed variant

Applies when Rm != 11x1.

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then UNDEFINED;
case type of
    when '0000'
        inc = 1;
    when '0001'
        inc = 2;
    otherwise
        SEE "Related encodings";
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Offset variant

Applies when Rm == 1111.

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Post-indexed variant

Applies when Rm == 1101.

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Post-indexed variant

Applies when Rm != 11x1.

VST4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then UNDEFINED;
case type of
  when '0000'
    inc = 1;
  when '0001'
    inc = 2;
  otherwise
    SEE "Related encodings";
alignment = if align == '00' then 1 else 4 << UInt(align);
ebytes = 1 << UInt(size); elements = 8 DIV ebytes;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VST4 \(multiple 4-element structures\)](#) on page K1-5473.

Related encodings: See [Advanced SIMD element or structure Load/Store on page F3-2479](#) for the T32 instruction set, or [Advanced SIMD element or structure Load/Store on page F4-2553](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
 The encoding size = 11 is reserved.
- <list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
 { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
 Single-spaced registers, encoded in the "type" field as 0b0000.
 { <Dd>, <Dd+2>, <Dd+4>, <Dd+6> }
 Double-spaced registers, encoded in the "type" field as 0b0001.
 The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are:
 64 64-bit alignment, encoded in the "align" field as 0b01.
 128 128-bit alignment, encoded in the "align" field as 0b10.
 256 256-bit alignment, encoded in the "align" field as 0b11.
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address, ebytes] = Elem[D[d], e];
        MemU[address+ebytes, ebytes] = Elem[D[d2], e];
        MemU[address+2*ebytes, ebytes] = Elem[D[d3], e];
        MemU[address+3*ebytes, ebytes] = Elem[D[d4], e];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;
  
```

F6.1.220 VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the alias VPUSH. See [Alias conditions on page F6-3747](#) for details of when each alias is preferred.

A1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
 VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

A2

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>

Increment After variant

Applies when P == 0 && U == 1.

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>
VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE; add = (U == '1'); wback = (W == '1'); d = UInt(Vd:D); n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;

```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
 VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T2

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>

Increment After variant

Applies when P == 0 && U == 1.

VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>
 VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
  
```

```
single_regs = TRUE; add = (U == '1'); wback = (W == '1'); d = UInt(Vd:D); n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32); regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VSTM on page K1-5473](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move on page F3-2448](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move on page F4-2532](#) for the A32 instruction set.

Alias conditions

| Alias | is preferred when |
|-------|---|
| VPUSH | <code>P == '1' && U == '0' && W == '1' && Rn == '1101'</code> |

Assembler symbols

| | |
|------------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <size> | An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecates use of the PC. |
| ! | Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0. |
| <sreglist> | Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register. |
| <dreglist> | Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r]; address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

F6.1.221 VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

VSTR{<c>}{<q>}{.32} <Sd>, [<Rn>{, #<+/-><imm>}]

Double-precision scalar variant

Applies when size == 11.

VSTR{<c>}{<q>}{.64} <Dd>, [<Rn>{, #<+/-><imm>}]

Decode for all variants of this encoding

```

if size IN { '00', '01' } then UNDEFINED;
esize = 8 << UInt(size); add = (U == '1');
imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
    
```

T1

Single-precision scalar variant

Applies when size == 10.

VSTR{<c>}{<q>}{.32} <Sd>, [<Rn>{, #<+/-><imm>}]

Double-precision scalar variant

Applies when size == 11.

VSTR{<c>}{<q>}{.64} <Dd>, [<Rn>{, #<+/-><imm>}]

Decode for all variants of this encoding

```

if size IN { '00', '01' } then UNDEFINED;
esize = 8 << UInt(size); add = (U == '1');
imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
if n == 15 && CurrentInstrSet() != InstrSet_A32 then UNPREDICTABLE;
    
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|-------|---|
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| .64 | Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Dd> | Is the 64-bit name of the SIMD&FP source register, encoded in the "D:Vd" field. |
| .32 | Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Sd> | Is the 32-bit name of the SIMD&FP source register, encoded in the "Vd:D" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <imm> | Is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    case esize of
        when 32
            MemA[address,4] = S[d];
        when 64
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d]<63:32> else D[d]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d]<31:0> else D[d]<63:32>;
```

F6.1.222 VSUB (floating-point)

Vector Subtract (floating-point) subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding A2, T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

- <dt> Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
 F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sn> Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
- <Sm> Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                Elem[D[d+r],e,esize] = FPSub(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize],
                StandardFPCRValue());
    else // VFP instruction
        case esize of
            when 32
                S[d] = FPSub(S[n], S[m], FPCR);
            when 64
                D[d] = FPSub(D[n], D[m], FPCR);
  
```

F6.1.223 VSUB (integer)

Vector Subtract (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

128-bit SIMD vector variant

Applies when Q == 1.

VSWP{<c>}{<q>}{. <dt>} <Qd>, <Qm>

Decode for all variants of this encoding

```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

- For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    if d == m then
        D[d+r] = bits(64) UNKNOWN;
    else
        D[d+r] = Din[m+r];
        D[m+r] = Din[d+r];
```

F6.1.228 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|----|----|---|---|----|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

VTBL variant

Applies when op == 0.

VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>

VTBX variant

Applies when op == 1.

VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>

Decode for all variants of this encoding

```
is_vtbl = (op == '0'); length = UInt(len)+1;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If n + length > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | |

    Elem[D[d],i,8] = Zeros(8);  
  // else Elem[D[d],i,8] unchanged
```

F6.1.229 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VTRN doubleword operations.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instructions [VUZP \(alias\)](#) and [VZIP \(alias\)](#). The pseudo-instruction is never the preferred disassembly.

Alias conditions

| Pseudo-instruction | is preferred when |
|--------------------|-------------------|
| VUZP (alias) | Never |
| VZIP (alias) | Never |

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
 - 8 when size = 00
 - 16 when size = 01
 - 32 when size = 10
 The encoding size = 11 is reserved.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  h = elements DIV 2;

  for r = 0 to regs-1
    if d == m then
      D[d+r] = bits(64) UNKNOWN;
    else
```

```
for e = 0 to h-1  
  Elem[D[d+r],2*e+1,esize] = Elem[Di[m+r],2*e,esize];  
  Elem[D[m+r],2*e,esize] = Elem[Di[d+r],2*e+1,esize];
```

F6.1.230 VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VTST{<c>}{<q>}.<dt> {<Dd>}, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VTST{<c>}{<q>}.<dt> {<Qd>}, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VTST{<c>}{<q>}.<dt> {<Dd>}, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VTST{<c>}{<q>}.<dt> {<Qd>}, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 - 8 when size = 00
 - 16 when size = 01
 - 32 when size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if !IsZero(Elem[D[n+r],e,esize] AND Elem[D[m+r],e,esize]) then
        Elem[D[d+r],e,esize] = Ones(esize);
      else
        Elem[D[d+r],e,esize] = Zeros(esize);
```

F6.1.231 VUZP

Vector Unzip de-interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VUZP doubleword operation for data type 8.

VUZP.8, doubleword

| | Register state before operation | | | | | | | | Register state after operation | | | | | | | |
|----|---------------------------------|----|----|----|----|----|----|----|--------------------------------|----|----|----|----|----|----|----|
| Dd | A7 | A6 | A5 | A4 | A3 | A2 | A1 | A0 | B6 | B4 | B2 | B0 | A6 | A4 | A2 | A0 |
| Dm | B7 | B6 | B5 | B4 | B3 | B2 | B1 | B0 | B7 | B5 | B3 | B1 | A7 | A5 | A3 | A1 |

The following figure shows an example of the operation of VUZP quadword operation for data type 32.

VUZP.32, quadword

| | Register state before operation | | | | Register state after operation | | | |
|----|---------------------------------|----|----|----|--------------------------------|----|----|----|
| Qd | A3 | A2 | A1 | A0 | B2 | B0 | A2 | A0 |
| Qm | B3 | B2 | B1 | B0 | B3 | B1 | A3 | A1 |

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> For the 64-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 The encoding size = 1x is reserved.
 For the 128-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
 The encoding size = 11 is reserved.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  if quadword_operation then
    if d == m then
      Q[d>>1] = bits(128) UNKNOWN; Q[m>>1] = bits(128) UNKNOWN;
    else
      zipped_q = Q[m>>1]:Q[d>>1];
      for e = 0 to (128 DIV esize) - 1
        Elem[Q[d>>1],e,esize] = Elem[zipped_q,2*e,esize];
        Elem[Q[m>>1],e,esize] = Elem[zipped_q,2*e+1,esize];
  else
    if d == m then
      D[d] = bits(64) UNKNOWN; D[m] = bits(64) UNKNOWN;
    else
      zipped_d = D[m]:D[d];
      for e = 0 to (64 DIV esize) - 1
        Elem[D[d],e,esize] = Elem[zipped_d,2*e,esize];
        Elem[D[m],e,esize] = Elem[zipped_d,2*e+1,esize];
```

F6.1.232 VUZP (alias)

Vector Unzip de-interleaves the elements of two vectors

This instruction is a pseudo-instruction of the [VTRN](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VTRN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VTRN](#) gives the operational pseudocode for this instruction.

A1

64-bit SIMD vector variant

VUZP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.32 <Dd>, <Dm>

and is never the preferred disassembly.

T1

64-bit SIMD vector variant

VUZP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.32 <Dd>, <Dm>

and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

The description of [VTRN](#) gives the operational pseudocode for this instruction.

F6.1.233 VZIP

Vector Zip interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VZIP doubleword operation for data type 8.

VZIP.8, doubleword

| | Register state before operation | | | | | | | | Register state after operation | | | | | | | |
|----|---------------------------------|----|----|----|----|----|----|----|--------------------------------|----|----|----|----|----|----|----|
| Dd | A7 | A6 | A5 | A4 | A3 | A2 | A1 | A0 | B3 | A3 | B2 | A2 | B1 | A1 | B0 | A0 |
| Dm | B7 | B6 | B5 | B4 | B3 | B2 | B1 | B0 | B7 | A7 | B6 | A6 | B5 | A5 | B4 | A4 |

The following figure shows an example of the operation of VZIP quadword operation for data type 32.

VZIP.32, quadword

| | Register state before operation | | | | Register state after operation | | | |
|----|---------------------------------|----|----|----|--------------------------------|----|----|----|
| Qd | A3 | A2 | A1 | A0 | B1 | A1 | B0 | A0 |
| Qm | B3 | B2 | B1 | B0 | B3 | A3 | B2 | A2 |

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

D[d] = zipped_d<63:0>; D[m] = zipped_d<127:64>;
```

F6.1.234 VZIP (alias)

Vector Zip interleaves the elements of two vectors

This instruction is a pseudo-instruction of the [VTRN](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VTRN](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VTRN](#) gives the operational pseudocode for this instruction.

A1

64-bit SIMD vector variant

VZIP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.32 <Dd>, <Dm>

and is never the preferred disassembly.

T1

64-bit SIMD vector variant

VZIP{<c>}{<q>}.32 <Dd>, <Dm>

is equivalent to

VTRN{<c>}{<q>}.32 <Dd>, <Dm>

and is never the preferred disassembly.

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

The description of [VTRN](#) gives the operational pseudocode for this instruction.

Part G

The AArch32 System Level Architecture

Chapter G1

The AArch32 System Level Programmers' Model

This chapter gives a system level description of the programmers' model for execution in AArch32 state. It contains the following sections:

- *About the AArch32 System level programmers' model on page G1-3782.*
- *Exception levels on page G1-3783.*
- *Exception terminology on page G1-3784.*
- *Execution state on page G1-3786.*
- *Instruction Set state on page G1-3788.*
- *Security state on page G1-3789.*
- *Security state, Exception levels, and AArch32 execution privilege on page G1-3792.*
- *Virtualization on page G1-3794.*
- *AArch32 PE modes, and general-purpose and Special-purpose registers on page G1-3796.*
- *Process state, PSTATE on page G1-3805.*
- *Instruction set states on page G1-3810.*
- *Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812.*
- *Exception return to an Exception level using AArch32 on page G1-3834.*
- *Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839.*
- *AArch32 state exception descriptions on page G1-3849.*
- *Reset into AArch32 state on page G1-3868.*
- *Mechanisms for entering a low-power state on page G1-3872.*

G1.1 About the AArch32 System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features that are required for one or both of an operating system (OS) and a hypervisor to provide the programming environment seen by an application. This chapter describes the System level programmers' model when executing at EL1 or higher in an Exception level that is using AArch32.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

The following sections give a system level introduction to the basic concepts of the ARM architecture AArch32 state, and the terminology that is used for describing the architecture when executing in this state:

- [Exception levels on page G1-3783.](#)
- [Exception terminology on page G1-3784.](#)
- [Execution state on page G1-3786.](#)
- [Instruction Set state on page G1-3788.](#)
- [Security state on page G1-3789.](#)
- [Virtualization on page G1-3794.](#)

The rest of this chapter describes the system level programmers' model when executing in AArch32 state.

The other chapters in this part describe:

- The memory system architecture, as seen when executing in an Exception level that is using AArch32:
 - [Chapter G3 The AArch32 System Level Memory Model](#) describes the general features of the ARMv8 memory model, when executing in AArch32 state, that are not visible at the application level.

———— **Note** —————

[Chapter E2 The AArch32 Application Level Memory Model](#) describes the application level view of the memory model.

- [Chapter G4 The AArch32 Virtual Memory System Architecture](#) describes the Virtual Memory System Architecture (VMSA) used in AArch32 state.

- The AArch32 System Registers, see [Chapter G6 AArch32 System Register Descriptions](#).

———— **Note** —————

The T32 and A32 instruction sets include instructions that provide system level functionality, such as returning from an exception. See for example, [ERET on page F5-2673](#).

G1.2 Exception levels

The ARMv8-A architecture defines a set of Exception levels, EL0 to EL3, where:

- If EL n is the Exception level, increased values of n indicate increased software execution privilege.
- Execution at EL0 is called *unprivileged execution*.
- EL2 provides support for virtualization of Non-secure operation.
- EL3 provides support for switching between two Security states, Secure state and Non-secure state.

An implementation might not include all of the Exception levels. All implementations must include EL0 and EL1. EL2 and EL3 are optional.

———— Note ————

A PE is not required to implement a contiguous set of Exception levels. For example, it is permissible for an implementation to include only EL0, EL1, and EL3.

The effect of implementation choices on the programmers' model on page D1-1619 provides information on implementations.

When executing in AArch32 state, execution can move between Exception levels only on taking an exception or on returning from an exception:

- On taking an exception, the Exception level can only increase or remain the same.
- On returning from an exception, the Exception level can only decrease or remain the same.

The Exception level that execution changes to or remains in on taking an exception is called the *target Exception level* of the exception.

Each exception type has a target Exception level that is either:

- Implicit in the nature of the exception.
- Defined by configuration bits in the System registers.

An exception cannot target EL0.

Exception levels exist within *Security states*. *The ARMv8-A security model on page G1-3789* describes this. When executing at an Exception level, the PE can access both of the following:

- The resources that are available for the combination of the current Exception level and the current Security state.
- The resources that are available at all lower Exception levels, provided that those resources are available to the current Security state.

This means that if the implementation includes EL3, then because EL3 is only implemented in Secure state, execution at EL3 can access all resources available at all Exception levels, for both Security states.

Each Exception level other than EL0 has its own translation regime and associated control registers. For information on the translation regimes, see *Chapter G4 The AArch32 Virtual Memory System Architecture*.

G1.2.1 Typical Exception level usage model

The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

| | |
|------------|--|
| EL0 | Applications. |
| EL1 | OS kernel and associated functions that are typically described as <i>privileged</i> . |
| EL2 | Hypervisor. |
| EL3 | Secure monitor. |

G1.3 Exception terminology

The following subsections define the terms that are used when describing exceptions:

- [Terminology for taking an exception.](#)
- [Terminology for returning from an exception.](#)
- [Exception levels.](#)
- [Definition of a precise exception.](#)
- [Definitions of synchronous and asynchronous exceptions on page G1-3785.](#)

G1.3.1 Terminology for taking an exception

An exception is *generated* when the PE first responds to an exceptional condition. The PE state at this time is the state that the exception is *taken from*. The PE state immediately after taking the exception is the state that the exception is *taken to*.

G1.3.2 Terminology for returning from an exception

To return from an exception, the PE must execute an exception return instruction. The PE state when an exception return instruction is committed for execution is the state the exception *returns from*. The PE state immediately after the execution of that instruction is the state that the exception *returns to*.

G1.3.3 Exception levels

An Exception level, EL_n , with a larger value of n than another Exception level, is described as being a *higher* Exception level than the other Exception level. For example, EL_3 is a higher Exception level than EL_1 .

An Exception level with a smaller value of n than another Exception level is described as being a *lower* Exception level than the other Exception level. For example, EL_0 is a lower Exception level than EL_1 .

An Exception level is described as:

- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

G1.3.4 Definition of a precise exception

An exception is described as *precise* when the exception handler receives the PE state and memory system state that is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken, and none afterwards.

Other than the SError interrupt all exceptions that are taken to AArch32 state are required to be precise. For each occurrence of an SError interrupt, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

Where a synchronous exception that is taken to AArch32 state is generated as part of an instruction that performs more than one single-copy atomic memory access, the definition of precise permits that the values in registers or memory affected by those instructions can be UNKNOWN, provided that:

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions.
- The registers are not involved in the calculation of the memory address that is used by the instruction.

In AArch32 state, examples of instructions that perform more than one single-copy atomic memory access are the LDM and STM instructions.

———— **Note** —————

- For the definition of a single-copy atomic access, see [Properties of single-copy atomic accesses on page E2-2329.](#)
- The SError interrupt replaces the ARMv7 asynchronous abort.

G1.3.5 Definitions of synchronous and asynchronous exceptions

An exception is described as *synchronous* if all of the following apply:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- The exception is precise.

An exception is described as *asynchronous* if any of the following apply:

- The exception is not generated as a result of direct execution or attempted execution of the instruction stream.
- The return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.
- The exception is imprecise.

For more information about exceptions, see [Handling exceptions that are taken to an Exception level using AArch32](#) on page G1-3812.

G1.4 Execution state

The Execution states are:

AArch64 The 64-bit Execution state.

AArch32 The 32-bit Execution state. Operation in this state is compatible with ARMv7-A operation.

[Execution state on page A1-33](#) gives more information about them.

Exception levels *use* Execution states. For example, EL0, EL1 and EL2 might all be using AArch32, under EL3 using AArch64.

This means that:

- Different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.
- The PE can change Execution states only either:
 - At reset.
 - On a change of Exception level.

Note

- [Typical Exception level usage model on page G1-3783](#) shows which Exception levels different software layers might typically use.
- [The effect of implementation choices on the programmers' model on page D1-1619](#) gives information on supported configurations of Exception levels and Execution states.

The interaction between the AArch64 and AArch32 Execution states is called *interprocessing*. [Interprocessing on page D1-1607](#) describes this.

G1.4.1 About the AArch32 PE modes

AArch32 state provides a set of *PE modes* that support normal software execution and handle exceptions. The current mode determines the set of registers that are available, as described in [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-3801](#).

The AArch32 modes are:

- Monitor mode. This mode always executes at Secure EL3.
- Hyp mode. This mode always executes at Non-secure EL2.
- System, Supervisor, Abort, Undefined, IRQ and FIQ modes. The Exception level these modes execute at depends on the Security state, as described in [Security state on page G1-3789](#).
- User mode. This mode always executes at EL0.

Note

AArch64 state does not support modes. Modes are a concept that is specific to AArch32 state. Modes that execute at a particular Exception level are only implemented if that Exception level supports using AArch32.

For more information on modes see [AArch32 PE mode descriptions on page G1-3796](#).

The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

All of the following define the mode that an exception is taken to:

- The type of exception.
- The mode the exception is taken from.
- Configuration settings defined at EL2 and EL3.

Monitor mode and Hyp mode can create system traps that cause exceptions to EL3 or EL2 respectively. There is an architected hierarchy where EL2 and EL3 configuration settings affect a common condition, for example interrupt routing. When no traps are enabled for a particular condition, the AArch32 mode an exception is taken to is called the *default mode* for that exception.

In AArch32 state, a number of different modes can exist at the same Exception level. All modes at a particular Exception level have the *execution privilege*, meaning they have the same access rights for accesses to memory and to System registers. However, the mapping of PE modes to Exception levels depends on the Security state, as described in [Security state on page G1-3789](#). [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#) gives more information about the PE modes, their associated execution privilege, and how this maps onto the Exception levels.

G1.5 Instruction Set state

In AArch32 state, the *Instruction Set state* determines the instruction set that the PE is executing. In an implementation that follows the ARM recommendations, the available Instruction Set states are:

T32 state The PE is executing T32 instructions.

A32 state The PE is executing A32 instructions.

———— **Note** —————

In previous versions of the ARM architecture:

- The T32 instruction set was called the Thumb instruction set.
- The A32 instruction set was called the ARM instruction set.

—————
For more information, see [Process state, PSTATE](#) on page E1-2294.

G1.6 Security state

The ARMv8-A architecture provides two Security states, each with an associated physical memory address space, as follows:

| | |
|-------------------------|--|
| Secure state | When in this state, the PE can access both the Secure physical address space and the Non-secure physical address space. |
| Non-secure state | When in this state, the PE: <ul style="list-style-type: none"> • Can access only the Non-secure physical address space. • Cannot access the Secure system control resources. |

For information on how virtual addresses translate onto Secure physical and Non-secure addresses, see [About VMSAv8-32 on page G4-4022](#).

G1.6.1 The ARMv8-A security model

The general principles of the ARMv8-A security model are:

- If the implementation includes EL3 then it has two Security states, Secure and Non-secure, and:
 - EL3 exists only in Secure state.
 - A change from Non-secure state to Secure state can only occur on taking an exception to EL3.
 - A change from Secure state to Non-secure state can only occur on an exception return from EL3.
 - If EL2 is implemented, it exists only in Non-secure state.
- If the implementation does not include EL3 it has one Security state, that is:
 - IMPLEMENTATION DEFINED, if the implementation does not include EL2.
 - Non-secure state if the implementation includes EL2.

The AArch32 security model, and execution privilege

The Exception level hierarchy of four Exception levels, EL0, EL1, EL2, and EL3, applies to execution in both Execution states. This section describes the mapping between Exception levels, AArch32 modes, and execution privilege.

The AArch32 modes Monitor, System, Supervisor, Abort, Undefined, IRQ, and FIQ all have the same execution privilege.

In Secure state:

- Monitor mode executes only at EL3, and is accessible only when EL3 is using AArch32.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode all:
 - Execute at EL1 when EL3 is using AArch64.
 - Execute at EL3 when EL3 is using AArch32.

This means that there is a difference in the Secure state hierarchy that the PE is using, depending on which Execution state EL3 is using:

- If EL3 is using AArch64:
 - There is no support for Monitor mode.
 - If EL1 is using AArch32, System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL1.
- If EL3 is using AArch32:
 - Monitor mode is supported, and executes at Secure EL3
 - System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode execute at Secure EL3.
 - There is no support for a Secure EL1 Exception level.

See [Security behavior in Exception levels using AArch32 when EL3 is using AArch64](#) on page G1-3824 for more information about operation in a Secure EL1 mode when EL3 is using AArch64.

In Non-secure state, the PL1 modes System, Supervisor, Abort, Undefined, IRQ, and FIQ always execute at EL1. User mode always executes at EL0 and has the lowest possible execution privilege.

Hyp mode always executes in Non-secure state at EL2 and has higher execution privilege than all of:

- User mode.
- System mode, Supervisor mode, Abort mode, Undefined mode, IRQ mode, and FIQ mode.

[Limited use of Privilege level in ARMv8 AArch32 state](#) on page G1-3793 describes how, in some contexts, the concept of *Privilege levels* can be used to represent the execution privilege hierarchy.

For more information about the modes see [About the AArch32 PE modes](#) on page G1-3786.

Figure G1-1 shows the security model when EL3 is using AArch32, and shows the expected use of the different Exception levels, and which modes execute at which Exception levels.

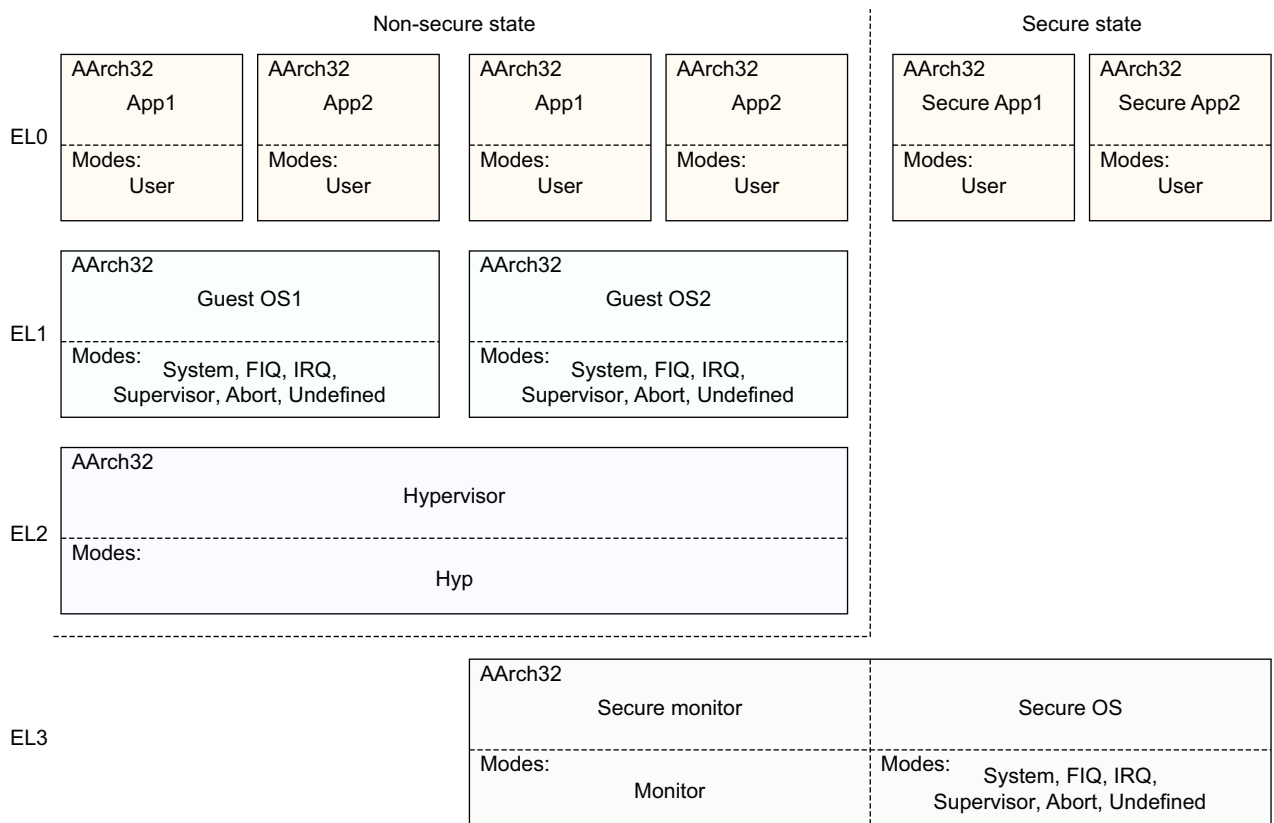

Figure G1-1 ARMv8-A Security model when EL3 is using AArch32

Note

For an overview of the Security models when EL3 is using AArch64:

- See [Figure G1-2 on page G1-3799](#) for the case where EL2, EL1, and EL0 are all using AArch32. This figure shows the implementation of the PE modes.
- See [Figure D1-1 on page D1-1503](#) for an overview of the set of possible implementations.

Figure G1-1 on page G1-3790 shows that when EL3 is using AArch32, the Exception levels and modes available in each Security state are as follows:

Secure state

- EL0** User mode.
- EL3** Any mode that is available in Secure state, other than User mode.

Non-secure state

- EL0** User mode.
- EL1** Any mode that is available in Non-secure state, other than Hyp mode and User mode.
- EL2** Hyp mode.

Execution at EL0 is described as *unprivileged execution*.

A mode associated with a particular Exception level, EL_n , is described as an EL_n mode.

———— Note —————

The Exception level defines the ability to access resources in the current Security state, and does not imply anything about the ability to access resources in the other Security state.

When EL3 is using AArch32, many AArch32 System registers accessible at PL1 are *banked* between the Secure and Non-secure states.

When EL3 is using AArch64 and Secure EL1 is using AArch32, System registers accessible at PL1 are not banked between the Non-secure and Secure states. Software running at EL3 is expected to switch the content of the PL1-accessible System registers between the Secure and Non-secure context, in a similar manner to switching the contents of general purpose registers. For information on the relationship between AArch64 and AArch32 System registers in an interprocessing environment, see [Mapping of the System registers between the Execution states on page D1-1610](#).

For more information on the System registers, see [The AArch32 System register interface on page G1-3877](#).

The *Secure Monitor Call* (SMC) instruction provides software with a system call to EL3. When executing at a privileged Exception level, SMC instructions generates exceptions. For more information, see [Secure Monitor Call \(SMC\) exception on page G1-3854](#) and [SMC on page F5-2983](#).

———— Note —————

For more information about the Privilege level terminology, see [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#).

Changing from Secure state to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. When executing in an Exception level that is using AArch32, except in Monitor mode and Hyp mode, the Security state is controlled:

- By the **SCR.NS** bit, when EL3 is using AArch32.
- By the **SCR_EL3.NS** bit, when EL3 is using AArch64.

The mapping of AArch32 privileged modes to the exception hierarchy means that it is possible when EL3 is using AArch32 to change from EL3 to Non-secure EL1 without an exception return. This can occur in one of the following ways:

- Using an MSR or CPS instruction to switch from Monitor mode to another privileged mode while **SCR.NS** is 1.
- Using an MCR instruction that writes **SCR.NS** to change from Secure to Non-secure state when in a privileged mode other than Monitor mode.

ARM strongly recommends that software executing at EL3 using AArch32 does not use either of these mechanisms to change from EL3 to Non-secure EL1 without an exception return. The use of both of these mechanisms is deprecated.

G1.7 Security state, Exception levels, and AArch32 execution privilege

In ARMv8, the hierarchy of software execution privilege, within a particular Security state, is defined by the Exception levels, with higher Exception level numbers indicating higher privilege. Table G1-1 shows this hierarchy for each Security state.

Table G1-1 Execution privilege and Exception levels, by Security state

| Execution privilege | Secure state | Non-secure state | Typical use |
|----------------------|----------------|------------------|----------------------------------|
| Highest | EL3 | - ^a | Secure monitor |
| - | - ^a | EL2 | Hypervisor |
| - | EL1 | EL1 | Secure or Non-secure OS |
| Lowest, Unprivileged | EL0 | EL0 | Secure or Non-secure application |

a. EL2 is never implemented in Secure state, and EL3 is never implemented in Non-secure state.

When executing in AArch32 state, within a given Security state, the current PE state, including the execution privilege, is primarily indicated by the current *PE mode*. In Secure state, how the PE modes map onto the Exception levels depends on whether EL3 is using AArch32 or is using AArch64, and:

- Figure G1-1 on page G1-3790 shows this mapping when EL3 is using AArch32.
- Figure G1-2 on page G1-3799 shows this mapping when EL3 is using AArch64.

Table G1-2 shows this mapping. In interpreting this table:

- Monitor mode is implemented only in Secure state, and only if EL3 is using AArch32.
- Hyp mode is implemented only in Non-secure state, and only if EL2 is using AArch32.
- System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented:
 - In Secure state** If either:
 - EL3 is using AArch32.
 - EL3 is using AArch64 and EL1 is using AArch32.
 - In Non-secure state** If EL1 is using AArch32.
- User mode is implemented if EL0 is using AArch32.

Table G1-2 Mapping of AArch32 PE modes to Exception levels

| Exception level | PE modes in the given Security state, and EL3 Execution state | | |
|-----------------|---|--|--|
| | Secure state, EL3 using AArch32 | Secure state, EL3 using AArch64 | Non-secure state |
| EL3 | Monitor, System, FIQ, IRQ, Supervisor, Abort, Undefined | - | - |
| EL2 | - | - | Hyp |
| EL1 | - | System, FIQ, IRQ, Supervisor, Abort, Undefined | System, FIQ, IRQ, Supervisor, Abort, Undefined |
| EL0 | User | User | User |

Because AArch32 behavior is described in terms of the PE modes, and transitions between PE modes, the Exception levels are implicit in most of the description of operation in AArch32 state.

G1.7.1 Limited use of Privilege level in ARMv8 AArch32 state

As described in *The VMSAv8-32 translation regimes on page G4-4024*, a *translation regime* maps a virtual address (VA) to the corresponding physical address (PA). The VMSAv8-64 translation regimes are defined by the Exception levels that use them. However, because the mapping between PE modes and Exception levels in Secure state depends on whether EL3 is using AArch32 or is using AArch64, as shown in [Table G1-2 on page G1-3792](#), the VMSAv8-32 translation regimes cannot be described simply in terms of either the Exception levels or the PE modes that use them.

To provide a consistent description of address translation as seen from AArch32 state, the VMSAv8-32 translation regimes are described in terms of the *Privilege levels* originally defined in the ARMv7 descriptions of AArch32 state. [Table G1-3](#) shows how the PE modes map to these Privilege levels:

Table G1-3 Mapping of PE modes to AArch32 Privilege levels

| Privilege level | Secure state | Non-secure state |
|-----------------|---|--|
| PL2 | - | Hyp ^a |
| PL1 | Monitor ^b , System, FIQ, IRQ, Supervisor, Abort, Undefined | System, FIQ, IRQ, Supervisor, Abort, Undefined |
| PL0 | User | User |

- a. Implemented only in Non-secure state, and only if EL2 is using AArch32
- b. Implemented only in Secure state, and only if EL3 is using AArch32.

Comparing [Table G1-3](#) with [Table G1-2 on page G1-3792](#) shows that:

In Non-secure state

Each privilege level maps to the corresponding Exception level. For example PL1 maps to EL1.

In Secure state

PL0 maps to EL0.

The mapping of PL1 depends on the Execution state being used by EL3, as follows:

EL3 using AArch64 Secure PL1 maps to Secure EL1. Monitor mode is not implemented.

EL3 using AArch32 Secure PL1 maps to Secure EL3. Monitor mode is implemented as one of the Secure PL1 modes.

G1.8 Virtualization

The support for virtualization described in this section applies only to an implementation that includes EL2. A PE is in *Hyp mode* when it is executing at EL2 in the AArch32 state. An exception return from Hyp mode to software running at EL1 or EL0 is performed using the ERET instruction.

EL2 provides a set of features that support virtualizing the Non-secure state of an ARMv8-A implementation. The basic model of a virtualized system involves:

- A hypervisor, running in EL2, that is responsible for switching between *virtual machines*. A virtual machine is comprised of Non-secure EL1 and Non-secure EL0.
- A number of Guest operating systems, that each run in Non-secure EL1, on a virtual machine.
- For each Guest operating system, applications, that usually run in Non-secure EL0, on a virtual machine.

———— Note ————

In some systems, a Guest OS is unaware that it is running on a virtual machine, and is unaware of any other Guest OS. In other systems, a hypervisor makes the Guest OS aware of these facts. The ARMv8-A architecture supports both of these models.

The hypervisor assigns a *virtual machine identifier* (VMID) to each virtual machine.

EL2 is implemented only in Non-secure state, to support Guest OS management. EL2 provides controls to:

- Provide virtual values for the contents of a small number of identification registers. A read of one of these registers by a Guest OS or the applications for a Guest OS returns the virtual value.
- *Trap* various operations, including memory management operations and accesses to many other registers. A trapped operation generates an exception that is taken to EL2.
- Route interrupts to the appropriate one of:
 - The current Guest OS.
 - A Guest OS that is not currently running.
 - The hypervisor.

In Non-secure state:

- The implementation provides an independent *translation regime* for memory accesses from EL2.
- For the PL1&0 translation regime, address translation occurs in two stages:
 - Stage 1 maps the *virtual address* (VA) to an *intermediate physical address* (IPA). This is managed at EL1, usually by a Guest OS. The Guest OS believes that the IPA is the *physical address* (PA).
 - Stage 2 maps the IPA to the PA. This is managed at EL2. The Guest OS might be completely unaware of this stage.

For more information on the translation regimes, see [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

G1.8.1 The effect of implementing EL2 on the Exception model

An implementation that includes EL2 implements the following exceptions:

- Hypervisor Call (HVC) exception.
- Traps to EL2. [EL2 configurable controls on page G1-3894](#), describes these.
- All of the virtual interrupts:
 - Virtual SError.
 - Virtual IRQ.
 - Virtual FIQ.

HVC exceptions are always taken to EL2. All virtual interrupts are always taken to EL1, and can only be taken from Non-secure EL1 or EL0.

Each of the virtual interrupts can be independently enabled using controls at EL2.

Each of the virtual interrupts has a corresponding physical interrupt. See [Virtual interrupts](#).

When a virtual interrupt is enabled, its corresponding physical exception is taken to EL2, unless EL3 has configured that physical exception to be taken to EL3. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839](#).

An implementation that includes EL2 also:

- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure state, to EL2. For more information see:
 - [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).
 - [Routing debug exceptions to EL2 on page G1-3833](#).
- Provides mechanisms to trap PE operations to EL2. See [EL2 configurable controls on page G1-3894](#).
When an operation is trapped to EL2, the hypervisor typically either:
 - Emulates the required operation. The application running in the Guest OS is unaware of the trap.
 - Returns an error to the Guest OS.

Virtual interrupts

The virtual interrupts have names that correspond to the physical interrupts, as shown in [Table G1-4](#).

Table G1-4 The virtual interrupts

| Physical interrupt | Corresponding virtual interrupt |
|--------------------|---------------------------------|
| External SError | Virtual SError |
| IRQ | Virtual IRQ |
| FIQ | Virtual FIQ |

Software executing at EL2 can use virtual interrupts to signal physical interrupts to Non-secure EL1 and Non-secure EL0. [Example G1-1](#) shows a usage model for virtual interrupts.

Example G1-1 Virtual interrupt usage model

A usage model is as follows:

1. Software executing at EL2 routes a physical interrupt to EL2.
2. When a physical interrupt of that type occurs, the exception handler executing in EL2 determines whether the interrupt can be handled in EL2 or requires routing to a Guest OS in EL1. If the interrupt requires routing to a Guest OS:
 - If the Guest OS is currently running, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.
 - If the Guest OS is not currently running, the physical interrupt is marked as pending for the guest OS. When the hypervisor next switches to the virtual machine that is running that Guest OS, the hypervisor uses the appropriate virtual interrupt type to signal the physical interrupt to the Guest OS.

Non-secure EL1 and Non-secure EL0 modes cannot distinguish a virtual interrupt from the corresponding physical interrupt.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-3839](#).

G1.9 AArch32 PE modes, and general-purpose and Special-purpose registers

The following sections describe the AArch32 PE modes and the general-purpose registers and the PC:

- [AArch32 PE mode descriptions](#).
- [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-3801](#).
- [Saved Program Status Registers \(SPSRs\) on page G1-3803](#).
- [ELR_hyp on page G1-3804](#).

———— **Note** —————

The PC is included in the scope of this section because, in AArch32 state, it is defined as being part of the same register file as the general-purpose registers. That is, the AArch32 register file R0-R15 comprises:

- The general-purpose registers R0-R14.
- The PC, that can be described as R15.

G1.9.1 AArch32 PE mode descriptions

Table G1-5 shows the PE modes defined by the ARM architecture, for execution in AArch32 state. In this table:

- The *PE mode* column gives the name of each mode and the abbreviation used, for example, in the general-purpose register name suffixes used in [AArch32 general-purpose registers, the PC, and the Special-purpose registers on page G1-3801](#).
- The *Encoding* column gives the corresponding PSTATE.M field.
- The *Exception level* column gives the Exception level at which the mode is implemented, including dependencies on the current Security state and on whether EL3 is using AArch32, see [Exception levels on page G1-3783](#).

Table G1-5 AArch32 PE modes

| PE mode | Encoding | Security state | Exception level | Implemented |
|------------|-----------|----------------------|--------------------------------|--------------------------------------|
| User | usr 10000 | Both | EL0 | Always |
| FIQ | fiq 10001 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |
| IRQ | irq 10010 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |
| Supervisor | svc 10011 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |
| Monitor | mon 10110 | Secure | EL3 | If EL3 implemented and using AArch32 |
| Abort | abc 10111 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |
| Hyp | hyp 11010 | Non-secure | EL2 | If EL2 implemented and using AArch32 |
| Undefined | und 11011 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |
| System | sys 11111 | Non-secure Secure | EL1 EL1 or EL3 ^a | Always |

a. EL3 if EL3 is using AArch32. EL1 if EL3 is using AArch64 and EL1 is using AArch32.

Mode changes can be made under software control, or can be caused by an external or internal exception.

Notes on the AArch32 PE modes

PE modes are defined only in AArch32 state. Because each mode is implemented as part of a particular Exception level that is using AArch32, the set of available modes depends on which Exception levels are implemented and using AArch32, as described in [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

This section gives more information about each of the modes, when it is implemented.

User mode Software executing in User mode executes at EL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- Makes only unprivileged accesses to system resources, meaning it cannot access protected system resources.
- Makes only unprivileged access to memory.
- Cannot change mode except by causing an exception, see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#).

System mode System mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode

Supervisor mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

Supervisor mode is the default mode to which a Supervisor Call exception is taken. Executing a SVC (Supervisor Call) instruction generates a Supervisor Call exception.

In an implementation where the highest implemented Exception level is using AArch32, if that Exception level is EL3 or EL1, a PE enters Supervisor mode on Reset.

Abort mode Abort mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode

Undefined mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode FIQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode IRQ mode is implemented at EL1 or EL3, see [Effect of the EL3 Execution state on the PE modes and Exception levels on page G1-3799](#).

IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode Hyp mode is the Non-secure EL2 mode.

Hyp mode is entered on taking an exception from Non-secure state that must be taken to EL2.

In an implementation where the highest implemented Exception level is EL2 and EL2 uses AArch32 on reset, a PE enters Hyp mode on Reset.

The Hypervisor Call exception and Hyp Trap exception are implemented as part of EL2 and are always taken to Hyp mode.

———— **Note** —————

This means that Hypervisor Call and Hyp Trap exceptions cannot be taken from Secure state.

When the value of the Hypervisor Call enable bit, [SCR.HCE](#), is 1, executing an HVC (Hypervisor Call) instruction in a Non-secure EL1 mode generates a Hypervisor Call exception.

For more information, see [Hyp mode on page G1-3800](#).

Monitor mode

Monitor mode is the Secure EL3 mode. This means it is always in the Secure state, regardless of the value of the [SCR.NS](#) bit.

Monitor mode is the mode to which a Secure Monitor Call exception is taken. In a Non-secure EL1 mode, or a Secure EL3 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

When EL3 is using AArch32, some exceptions that are taken to a different mode by default can be configured to be taken to EL3, see [PE mode for taking exceptions on page G1-3822](#).

When EL3 is using AArch32, software executing in Monitor mode:

- Has access to both the Secure and Non-secure copies of System registers.
- Can perform an exception return to Secure state, or to Non-secure state.

This means that, when EL3 is using AArch32, Monitor mode provides the only recommended method of changing between the Secure and Non-secure Security states.

Secure and Non-secure modes

In an implementation that includes EL3, the names of most implemented modes can be qualified as Secure or Non-secure, to indicate whether the PE is also in Secure state or Non-secure state. For example:

- If a PE is in Supervisor mode and Secure state, it is in *Secure Supervisor mode*.
- If a PE is in User mode and Non-secure state, it is in *Non-secure User mode*.

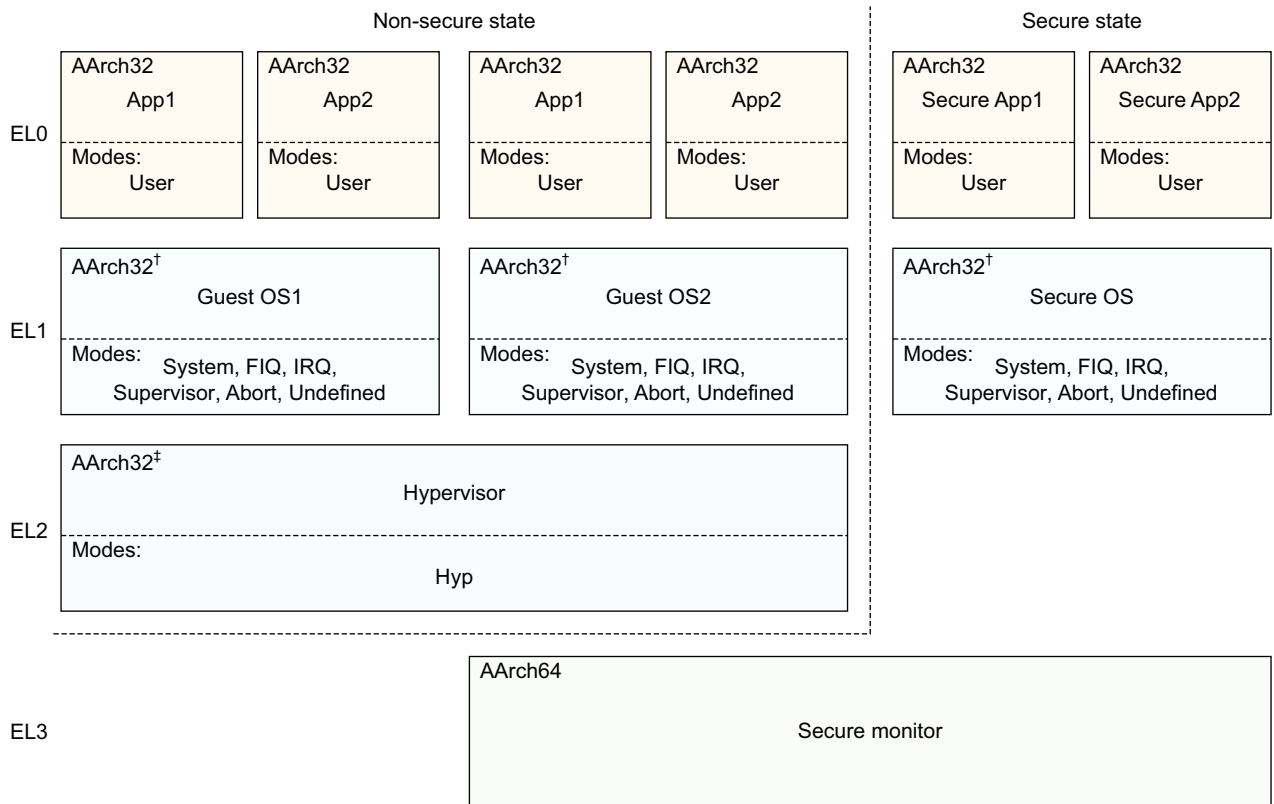

———— **Note** —————

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state.
- Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.

Effect of the EL3 Execution state on the PE modes and Exception levels

Figure G1-1 on page G1-3790 shows the PE modes, Exception levels, and Security states, for an implementation that includes all of the Exception levels, when EL3 is using AArch32. Figure G1-2 shows how the implemented modes change when EL3 is using AArch64.

† When EL1 is using AArch64, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are not implemented

‡ When EL2 is using AArch64, Hyp mode is not implemented

Figure G1-2 ARMv8 Exception levels, and PE modes, when EL3 is using AArch64

Comparing Figure G1-1 on page G1-3790 and Figure G1-2 shows how, in Secure state only, the implementation of System, FIQ, IRQ, Supervisor, Abort, and Undefined mode depends on the Execution state that EL3 is using. That is, these modes are implemented as follows:

Non-secure state

If Non-secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Non-secure state.

Secure state The implementation of these modes depends on the Execution state that EL3 is using, as follows:

EL3 using AArch64 If Secure EL1 is using AArch32 then System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL1. Otherwise, these modes are not implemented in Secure state.

EL3 using AArch32 In Secure state, System, FIQ, IRQ, Supervisor, Abort, and Undefined modes are implemented as part of EL3, see Figure G1-1 on page G1-3790.

Hyp mode

Hyp mode is the Non-secure EL2 mode. When EL2 is using AArch32, it provides the usual method of controlling the virtualization of Non-secure execution at EL1 and EL0.

Note

The alternative method of controlling this functionality is by accessing the EL2 controls from EL3 with the [SCR_EL3.NS](#) or [SCR.NS](#) bit set to 1.

This section summarizes how Hyp mode differs from the other modes, and references where this part of the manual describes the features of Hyp mode in more detail:

- Software executing in Hyp mode executes at EL2, see [Figure G1-1 on page G1-3790](#).
- Hyp mode is accessible only in Non-secure state. In Secure state, an attempt by a CPS or an MSR instruction to change [PSTATE.M](#) to Hyp mode is an illegal change to [PSTATE.M](#), as described in [Illegal changes to PSTATE.M on page G1-3809](#).
- In Non-debug state, the only mechanisms for changing to Hyp mode are:
 - An exception taken from a Non-secure EL1 or EL0 mode.
 - When EL3 is using AArch32, an exception return from Secure Monitor mode.
 - When EL3 is using AArch64, an exception return from EL3.
- In Hyp mode, the only exception return is execution of an ERET instruction, see [ERET on page F5-2673](#).
- In Hyp mode, the [CPACR](#) has no effect on the execution of;
 - System register access instructions.
 - Advanced SIMD and floating-point instructions.The [HCPTR](#) controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see [SVC on page F5-3129](#).
- An exception return with restored [PSTATE](#) specifying Hyp mode is an *illegal return event*, as described in [Illegal return events from AArch32 state on page G1-3835](#), if any of the following applies:
 - EL3 is using AArch64 and the value of [SCR_EL3.NS](#) is 0.
 - EL3 is using AArch32 and the value of [SCR.NS](#) is 0.
 - The return is from a Non-secure EL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
 - SRS. See [SRS, SRSDA, SRSD, SRSIA, SRSIB on page F5-3018](#).
 - RFE. See [RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-2918](#).
 - [LDM \(exception return\) on page F5-2703](#).
 - [LDM \(User registers\) on page F5-2705](#).
 - [STM \(User registers\) on page F5-3053](#).
 - The SUBS PC, LR forms of the instructions described in [SUB, SUBS \(immediate\) on page F5-3114](#).

Note

In T32 state, ERET is encoded as SUBS PC, LR, #0, and therefore this is a valid instruction.

- The exception return form of the instructions described in [MOV, MOVS \(register\) on page F5-2815](#).

In addition, deprecated forms of the A32 ADCS, ADDS, ANDS, BICS, EORS, MOVS, MVNS, ORRS, RSBS, RSCS, SBCS, and SUBS instructions with the PC as the destination register are UNDEFINED if executed in Hyp mode. The instruction descriptions identify these UNDEFINED cases.

- The Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are CONSTRAINED UNPREDICTABLE if executed in Hyp mode, see [Execution of Load/Store unprivileged instructions in Hyp mode on page K1-5475](#).

In an implementation that includes EL3, from reset, the HVC instruction is UNDEFINED in Non-secure EL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction:

- By setting the `SCR_EL3.HCE` bit to 1, if EL3 is using AArch64.
- By setting the `SCR.HCE` bit to 1, if EL3 is using AArch32.

When the HVC instruction is UNDEFINED in Non-secure EL1 modes because of the value of the `SCR_EL3.HCE` or `SCR.HCE` bit, HVC is CONSTRAINED UNPREDICTABLE in Hyp mode.

Pseudocode description of mode operations

The `BadMode()` function tests whether a 5-bit mode number corresponds to one of the permitted modes.

The `BadMode()` function is defined in [Chapter J1 ARMv8 Pseudocode](#).

G1.9.2 AArch32 general-purpose registers, the PC, and the Special-purpose registers

[The general-purpose registers, and the PC, in AArch32 state on page E1-2291](#) describes the application level view of the general-purpose registers, and the PC. This view provides:

- The general-purpose registers R0-R14, of which:
 - The preferred name for R13 is SP (*stack pointer*).
 - The preferred name for R14 is LR (*link register*).
- The PC (*program counter*), that can be described as R15.

These registers are selected from a larger set of registers, that includes *Banked* copies of some registers, with the current register selected by the execution mode. The implementation and banking of the general-purpose registers depends on whether or not the implementation includes EL2 and EL3, and whether those exception levels are using AArch32. [Figure G1-3 on page G1-3802](#) shows the full set of Banked general-purpose registers, and the Special-purpose registers:

- The Program Status Registers `CPSR` and `SPSR`.
- `ELR_hyp`.

———— Note —————

The architecture uses system level register names, such as `R0_usr`, `R8_usr`, and `R8_fiq`, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.

| Application level view | | System level view | | | | | | | |
|------------------------|---------|-------------------|------------------|------------|----------|-----------|----------------------|----------|----------|
| | User | System | Hyp [†] | Supervisor | Abort | Undefined | Monitor [‡] | IRQ | FIQ |
| R0 | R0_usr | | | | | | | | |
| R1 | R1_usr | | | | | | | | |
| R2 | R2_usr | | | | | | | | |
| R3 | R3_usr | | | | | | | | |
| R4 | R4_usr | | | | | | | | |
| R5 | R5_usr | | | | | | | | |
| R6 | R6_usr | | | | | | | | |
| R7 | R7_usr | | | | | | | | |
| R8 | R8_usr | | | | | | | | R8_fiq |
| R9 | R9_usr | | | | | | | | R9_fiq |
| R10 | R10_usr | | | | | | | | R10_fiq |
| R11 | R11_usr | | | | | | | | R11_fiq |
| R12 | R12_usr | | | | | | | | R12_fiq |
| SP | SP_usr | | SP_hyp | SP_svc | SP_abt | SP_und | SP_mon | SP_irq | SP_fiq |
| LR | LR_usr | | | LR_svc | LR_abt | LR_und | LR_mon | LR_irq | LR_fiq |
| PC | PC | | | | | | | | |
| APSR | CPSR | | | | | | | | |
| | | | SPSR_hyp | SPSR_svc | SPSR_abt | SPSR_und | SPSR_mon | SPSR_irq | SPSR_fiq |
| | | | ELR_hyp | | | | | | |

‡ Part of EL3. Exists only in Secure state, and only when EL3 is using AArch32.

† Part of EL2. Exists only in Non-secure state, and only when EL2 is using AArch32.

Cells with no entry indicate that the User mode register is used.

Figure G1-3 AArch32 general-purpose registers, PC, and Special-purpose registers, showing banking

As described in *PE mode for taking exceptions* on page G1-3822, on taking an exception the PE changes mode, unless it is already in the mode to which it must take the exception. Each mode that the PE might enter in this way has:

- A Banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
 - For the EL2 mode, Hyp mode, the Special-purpose register [ELR_hyp](#).
 - For the other privileged modes to which exceptions can be taken, a Banked copy of the link register, for example LR_und and LR_mon.
- A saved copy of **PSTATE**, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition FIQ mode has Banked copies of the general-purpose registers R8 to R12.

User mode and System mode share the same general-purpose registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2291.

AArch32 Special-purpose registers

In AArch32 state, the Special-purpose registers are:

- The [CPSR](#) and its view as the [APSR](#).
- The [SPSR](#), including the banked copies [SPSR_abt](#), [SPSR_fiq](#), [SPSR_hyp](#), [SPSR_irq](#), [SPSR_mon](#), [SPSR_svc](#), and [SPSR_und](#).
- The [ELR_hyp](#).

Pseudocode description of general-purpose register and PC operations

The following pseudocode gives access to the general-purpose registers and the PC. These registers are an array, `_R[]`, indexed by parameter `n`. This array is common to AArch32 and AArch64 operation and therefore contains 31 64-bit registers. `_PC` is the program counter, and its definition is common to AArch32 and AArch64 operation and therefore its size is 64-bit.

`LookUpRIndex()` looks up the index value, `n`, for the specified register number and PE mode, using `RBankSelect()` to evaluate the result.

`R[]` accesses the specified general-purpose register in the current PE mode, using `Rmode[]` to access the register, accessing `_R[]` if necessary. `SP` accesses the stack pointer, `LR` accesses the link register, and `PC` accesses the program counter. Each function has a non-assignment form for register reads and an assignment form for register writes, other than `PC`, which has only a non-assignment form.

`BranchTo()` performs a branch to the specified address.

The `_R[]`, `_PC`, `LR`, `SP`, `LookUpRIndex()`, `RBankSelect()`, `Rmode[]`, and `BranchTo()` functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

G1.9.3 Saved Program Status Registers (SPSRs)

The Saved Program Status Registers (SPSRs) are used to save PE state on taking exceptions. In AArch32 state, there is an SPSR for every mode that an exception can be taken to, as shown in [Figure G1-3 on page G1-3802](#). For example, the SPSR for Monitor mode is called `SPSR_mon`.

———— Note ————

Exceptions cannot be taken to EL0.

When the PE takes an exception, PE state is saved from `PSTATE` in the SPSR for the mode the exception is taken to. For example, if the PE takes an exception to Monitor mode, PE state is saved in `SPSR_mon`. For more information on `PSTATE`, see [Process state, PSTATE on page G1-3805](#).

———— Note ————

All `PSTATE` fields are saved, including those which have no direct read and write access.

Saving the `PSTATE` fields means the exception handler can:

- On return from the exception, restore the PE state to the values it had immediately before the exception was taken. When the PE returns from an exception, PE state is restored to the state stored in the SPSR of the mode the exception is returning from, if the exception return is made using one of:
 - `ERET`.
 - `LDM`.
 - The Exception return form of the instruction described in [MOV, MOVS \(register\) on page F5-2815](#).
 - The Exception return form of the instruction described in [SUB, SUBS \(immediate\) on page F5-3114](#).For example, on returning from Monitor mode, PE state is restored to the state stored in `SPSR_mon`. If the exception return is made using the `RFE` instruction, the PE restores the PE state from an SPSR valued read from memory.
- Examine the value that `PSTATE` had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure EL1 or EL0 mode makes `SPSR_hyp` UNKNOWN.

SPSR format for exceptions taken to AArch32 state

The SPSR bit assignments are:

N, Z, C, V, Q, GE[3:0], bits[31:27, 19:16]

Shows the value of the **PSTATE**. {N, Z, C, V, Q, GE} flags immediately before the exception was taken.

IT[1:0], J, IL, IT[7:2], E, T, bits[26:24, 20, 15:9, 5]

Shows the values of the **PSTATE**. {IT[7:0], J, IL, E, T} PE state controls immediately before the exception was taken. The J bit is RES0.

Bits[23:21] Reserved, RES0.

A, I, F, M, bits[8:6, 4:0]

Shows the values of the **PSTATE**. {A, I, F} exception mask and **PSTATE**.M mode bits immediately before the exception was taken.

Bits[23:21] of an SPSR are ignored on an exception return from AArch32 state.

Pseudocode description of SPSR operations

The following pseudocode gives access to the SPSRs.

The `SPSR[]` function accesses the current SPSR and is common to AArch32 and AArch64 operation.

The `SPSRWriteByInstr()` function is used by the `MSR (register)` and `MSR (immediate)` instructions to update the current SPSR.

The `SPSR[]` and `SPSRWriteByInstr()` functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

G1.9.4 ELR_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in `ELR_hyp`, a 32-bit Special-purpose register implemented for this purpose.

`ELR_hyp` can be accessed explicitly only by executing:

- An MRS or MSR instruction that targets `ELR_hyp`, see:
 - [MRS \(Banked register\) on page F5-2832](#).
 - [MSR \(Banked register\) on page F5-2836](#).

The `ERET` instruction uses the value in `ELR_hyp` as the return address for the exception. For more information, see [ERET on page F5-2673](#).

Software execution in any Non-secure EL1 or EL0 mode makes `ELR_hyp` UNKNOWN.

G1.10 Process state, PSTATE

In the ARMv8-A architecture, Process state or PSTATE is an abstraction of process state information. All of the instruction sets provide instructions that operate on elements of PSTATE.

PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

PSTATE is defined in pseudocode as the PSTATE structure, of type `ProcState`. `ProcState` is defined in [Chapter J1 ARMv8 Pseudocode](#).

The PSTATE fields that are meaningful in AArch32 state are:

The condition flags

| | |
|----------|--------------------------|
| N | Negative Condition flag. |
| Z | Zero Condition flag. |
| C | Carry Condition flag. |
| V | Overflow Condition flag. |

[Process state, PSTATE on page E1-2294](#) gives more information about these.

The overflow or saturation flag

| | |
|----------|---|
| Q | See Process state, PSTATE on page E1-2294 . |
|----------|---|

The greater than or equal flags

| | |
|----------------|---|
| GE[3:0] | See Process state, PSTATE on page E1-2294 . |
|----------------|---|

The PE state controls

| | |
|----------------|---|
| J, T | Instruction set state. See Process state, PSTATE on page E1-2294 . J is RES0. On a reset to AArch32 state, T is set to an IMPLEMENTATION DEFINED value. On taking an exception to: <ul style="list-style-type: none"> • A PL1 mode using AArch32, T is set to <code>SCTLR.TE</code>. • EL2 using AArch32, T is set to <code>HSCTLR.TE</code>. |
| IT[7:0] | IT block state bits. See Process state, PSTATE on page E1-2294 . On a reset or taking an exception to AArch32 state, these bits are set to 0. |
| E | Endianness of data accesses. See Process state, PSTATE on page E1-2294 . If an implementation provides both Big-endian and Little-endian support, then: <ul style="list-style-type: none"> • On a reset to AArch32 state this bit is set to the IMPLEMENTATION DEFINED reset value of: <ul style="list-style-type: none"> — <code>SCTLR.EE</code> if the highest implemented Exception level is not EL2. — <code>HSCTLR.EE</code> if the highest implemented Exception level is EL2. • On taking an exception to: <ul style="list-style-type: none"> — A PL1 mode using AArch32, this bit is set to <code>SCTLR.EE</code>. — EL2 using AArch32, this bit is set to <code>HSCTLR.EE</code> |
| IL | Illegal Execution state bit. See The Illegal Execution state exception on page G1-3837 . On a reset or taking an exception to AArch32 state, this bit is set to 0. |

For information on how the J, T, IT[7:0], E, and IL fields can be accessed, see [Accessing the PE state controls and the Execution state bit on page G1-3808](#).

The asynchronous exception mask bits

| | |
|----------|----------------------------|
| A | SError interrupt mask bit. |
| I | IRQ interrupt mask bit. |
| F | FIQ interrupt mask bit. |

For each bit, the values are:

- 0** Exception not masked.
- 1** Exception masked.

On a reset to AArch32 state, these bits are set to 1.

On taking an exception to AArch32 state, one or more of these bits are set to 1.

For more information, see both:

- [Asynchronous exception masking controls on page G1-3842.](#)
- [PE state on exception entry on page G1-3826.](#)

The mode bits

M[4:0] Current mode of the PE. [Table G1-5 on page G1-3796](#) lists the permitted values of this field. All other values are reserved. [Illegal changes to PSTATE.M on page G1-3809](#) describes the effect of setting M[4:0] to a reserved value.

M[4] is:

M[4], Execution state

The current Execution state:

- 0** AArch64 state.
- 1** AArch32 state.

———— Note ————

This is consistent with the use of M[4:0] in previous versions of the architecture.

On a reset to AArch32 state, M[4:0] is set to:

- 0b10011, meaning Supervisor mode, if the highest implemented Exception level is not EL2.
- 0b11010, meaning Hyp mode, if the highest implemented Exception level is EL2.

On taking an exception to AArch32 state, M[4:0] is set to the target mode for the exception type.

For more information about the PE modes, see:

- [AArch32 PE mode descriptions on page G1-3796.](#)
- [PE state on exception entry on page G1-3826.](#)

G1.10.1 Accessing PSTATE fields

The PSTATE fields can be accessed as described in the following subsections:

- [The Current Program Status Register, CPSR on page G1-3807.](#)
- [Accessing the PE state controls and the Execution state bit on page G1-3808.](#)
- [The CPS instruction on page G1-3808.](#)
- [The SETEND instruction on page G1-3808.](#)

The Current Program Status Register, CPSR

Some [PSTATE](#) fields can be accessed using the Special-purpose *Current Program Status Register* (CPSR). The CPSR can be directly read using the [MRS](#) instruction, and directly written using the [MSR \(register\)](#) and [MSR \(immediate\)](#) instructions.

The CPSR bit assignments are:

N, Z, C, V, bits [31:28]

The [PSTATE](#) condition flags.

Q, bit [27] The [PSTATE](#) overflow or saturation flag.

Bits[26:24] Reserved, RAZ/SBZP. Software can use MSR instructions that write the top byte of the CPSR without using a read-modify-write sequence. If it does this, it must write zeros to bits[26:24].

Bits[23:20, 15:10, 5]

Reserved, RES0.

GE[3:0], bits [19:16]

The [PSTATE](#) greater than or equal flags.

E, bit [9] The [PSTATE](#) endianness bit.

A, I, F, bits [8:6]

The [PSTATE](#) asynchronous exception mask bits.

M[4:0], bits [4:0]

The [PSTATE](#) mode bits.

The other [PSTATE](#) fields cannot be accessed by using the CPSR. For information on how to access them, see [Accessing the PE state controls and the Execution state bit on page G1-3808](#).

The application level alias for the CPSR is the [APSR](#). The [APSR](#) is a subset of the CPSR. See [The Application Program Status Register, APSR on page E1-2296](#).

Writes to the CPSR have side-effects on various aspects of PE operation. All of these side-effects, except side-effects on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means that they are guaranteed:

- Not to be visible to earlier instructions in the execution stream.
- To be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current Exception level and Security state. Writes to [PSTATE.M](#) can change one or both of the Exception level and Security state. The effect, on memory accesses associated with fetching instructions, of a change of Exception level or Security state is:

- Synchronous to the change of Exception level or Security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next [Context synchronization event](#) in the execution stream.

- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See [Exception return to an Exception level using AArch32](#) on page G1-3834 for the definition of exception return instructions.

Accessing the PE state controls and the Execution state bit

The PE state controls are the [PSTATE](#).{IL, IT[7:0], J, E, T} fields. Software can read or write these in an [SPSR](#).

In the [CPSR](#):

- The PE state controls, other than [PSTATE.E](#), are RAZ when read by an [MRS](#) instruction.
- Writes to the PE state controls, other than [PSTATE.E](#), by [MSR \(register\)](#) or [MSR \(immediate\)](#), are ignored in all modes.

Instructions other than [MRS](#), [MSR \(register\)](#), or [MSR \(immediate\)](#) that access the PE state controls can read and write them in any mode.

Unlike the other [PSTATE](#) PE state controls, [PSTATE.E](#) can be read by an [MRS](#) instruction and might be written by [MSR \(register\)](#) or [MSR \(immediate\)](#). However, ARM deprecates [PSTATE.E](#) having a different value from the equivalent System register EE bit, see [Mixed-endian support](#) on page G3-3988.

———— Note —————

To determine the current endianness, software can use an LDR instruction to load a word from memory with a known value that differs if the endianness is reversed. For example, using an LDR instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:

- 0x00000001 if the current endianness is little-endian.
- 0x01000000 if the current endianness is big-endian.

The [PSTATE.M](#)[4] bit is the Execution state bit. When read by an [MRS](#) instruction in AArch32 state, this bit always reads as 1. When written by an [MSR \(register\)](#) instruction or [MSR \(immediate\)](#) instruction, writing a value other than 1 is an illegal change to the [PSTATE.M](#) field. See [Illegal changes to PSTATE.M](#) on page G1-3809.

The CPS instruction

The A32 and T32 instruction sets both include an instruction to manipulate [PSTATE](#).{A, I, F} and [PSTATE.M](#):

CPSIE <iflags> {, #<mode>}

Sets the specified [PSTATE](#). {A, I, F} exception masks to 0, enabling the exception, and optionally changes to the specified mode.

CPSID <iflags> {, #<mode>}

Sets the specified [PSTATE](#).{A, I, F} exception masks to 1, disabling the exception, and optionally changes to the specified mode.

CPS #<mode> Changes to the specified mode without affecting the [PSTATE](#).{A, I, F} exception masks.

The CPS instruction is unconditional. For more information, see [CPS](#), [CPSID](#), [CPSIE](#) on page F5-2645.

The SETEND instruction

The A32 and T32 instruction sets both include an instruction to manipulate [PSTATE.E](#):

SETEND BE Sets [PSTATE.E](#) to 1, for big-endian operation.

SETEND LE Sets [PSTATE.E](#) to 0, for little-endian operation.

The SETEND instruction is unconditional. For more information, see [SETEND](#) on page F5-2966. ARM deprecates use of the SETEND instruction.

G1.10.2 The Saved Program Status Registers (SPSRs)

On taking an exception, **PSTATE** is preserved in the SPSR of the mode to which the exception is taken. The SPSRs are described in *Saved Program Status Registers (SPSRs)* on page G1-3803.

G1.10.3 Illegal changes to PSTATE.M

In AArch32 PE modes other than User mode, MSR and CPS instructions can explicitly change **PSTATE.M**. The following changes to **PSTATE.M** by MSR or CPS instructions are illegal:

- A change to an encoding that [Table G1-5 on page G1-3796](#) does not show.
- A change to a mode that is not implemented.
- A change to a mode that is not accessible from the context the MRS or CPS instruction is executed in, as follows:
 - A change to a mode that would cause entry to a higher Exception level.
 - When executing in Non-secure state, a change to Monitor mode.
 - When executing in Secure EL1, a change to Monitor mode when EL3 is using AArch64.
 - A change to Hyp mode from any other mode.
 - A change from Hyp mode to any other mode.
 - When the value of **HCR.TGE** is 1, attempting to change from Monitor mode to a Non-secure PL1 mode, see *Trapping of general exceptions to Hyp mode* on page K1-5476.

On executing an instruction that attempts an illegal change to **PSTATE.M**:

- **PSTATE.M** is unchanged, and the current mode remains unchanged.
- **PSTATE.IL** is set to 1.
- All other **PSTATE** fields are written to as normal.

————— Note —————

For the **PSTATE** fields that MSR and CPS instructions update, see the instruction descriptions:

- *MSR (register)* on page F5-2842.
- *MSR (immediate)* on page F5-2840.
- *CPS, CPSID, CPSIE* on page F5-2645.

When the value of **PSTATE.IL** is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception* on page G1-3837.

————— Note —————

- The PE ignores writes to **PSTATE.M** when executing at PL0.
- In ARMv7, an instruction that attempts to make an illegal change to **PSTATE.M** is UNPREDICTABLE.

G1.10.4 Pseudocode description of PSTATE operations

The `CPSRWriteByInstr()` function is used by the *MSR (register)* and *MSR (immediate)* instructions to update **PSTATE**.

The `SetPSTATEFromPSR()` function updates **PSTATE** from a CPSR or SPSR.

Chapter J1 *ARMv8 Pseudocode* defines these functions.

G1.11 Instruction set states

The instruction set states are described in [Chapter E2 The AArch32 Application Level Memory Model](#) and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- [Exceptions and instruction set state.](#)
- [Unimplemented instruction sets.](#)

G1.11.1 Exceptions and instruction set state

If an exception is taken to an EL1 mode, the [SCTLR.TE](#) bit for the Security state the exception is taken to determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the [HSCTLR.TE](#) bit determines the instruction set state that handles the exception, and if necessary, the PE changes to this instruction set state on exception entry.

On coming out of reset, if the highest implemented Exception level is using AArch32:

- If the highest implemented Exception level is EL2, the PE starts execution in Hyp mode, in the instruction set state determined by the reset value of [HSCTLR.TE](#).
- Otherwise, the PE starts execution in Supervisor mode, in the instruction set state determined by the reset value of [SCTLR.TE](#). If the implementation includes EL3, this execution is in Secure Supervisor mode.

For more information about exception entry, see [Overview of exception entry on page G1-3819](#).

G1.11.2 Unimplemented instruction sets

The [PSTATE.T](#) bit defines the current instruction set state, see [Process state, PSTATE on page E1-2294](#).

In the ARMv8 architecture there is no support for the hardware acceleration of Java bytecodes, and the Jazelle Instruction set state is obsolete. Every AArch32 implementation must support the Trivial Jazelle implementation described in [Trivial implementation of the Jazelle extension](#).

———— Note —————

In previous versions of the ARM architecture, the [PSTATE.{J, T}](#) bits determined the Instruction set state. In ARMv8, [PSTATE.J](#) is RES0.

Trivial implementation of the Jazelle extension

ARMv8 requires that the implementation of AArch32 state includes the trivial Jazelle implementation.

In a trivial implementation of the Jazelle extension:

- At EL1, EL2, or EL3, if the Exception level is using AArch32:
 - The [JMCR](#) and [JOSCR](#) are RAZ/WI.
 - The [JIDR](#) is a RAZ read-only register.
- At EL0 when EL0 is using AArch32:
 - It is IMPLEMENTATION DEFINED whether the [JMCR](#) and [JOSCR](#) are RAZ/WI or UNDEFINED.
 - It is IMPLEMENTATION DEFINED whether [JIDR](#) is RAZ or UNDEFINED.
- The [BXJ](#) instruction behaves identically to the [BX](#) instruction in all circumstances.

———— Note —————

This is consistent with the [JMCR.JE](#) bit being RAZ, and means that the A32 and T32 instruction sets do not provide any mechanism for attempting to enter Jazelle state.

- Jazelle state, as defined in previous versions of the ARM architecture, is an unimplemented instruction set state.

These requirements ensure that operating systems that support an EJVM execute correctly.

A trivial implementation is not required to extend the PC to 32 bits, that is, it can implement PC[0] as RAZ/WI.

———— **Note** —————

This is because the only way that PC[0] is visible in A32 or T32 state is as a result of an exception occurring during Jazelle state execution, and Jazelle state execution cannot occur on a trivial implementation.

G1.12 Handling exceptions that are taken to an Exception level using AArch32

An exception causes the PE to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the PE state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the PE is handling an exception.

The following sections describe exception handling:

- [Exception vectors and the exception base address.](#)
- [Exception prioritization for exceptions taken to AArch32 state on page G1-3816.](#)
- [Overview of exception entry on page G1-3819.](#)
- [PE mode for taking exceptions on page G1-3822.](#)
- [PE state on exception entry on page G1-3826.](#)
- [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828.](#)
- [Routing debug exceptions to EL2 on page G1-3833.](#)
- [Exception return to an Exception level using AArch32 on page G1-3834.](#)

[Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839](#) gives a full description of asynchronous exception handling, for exceptions taken asynchronously from AArch32 state.

———— Note ————

Because of the common model for handling exceptions, the current section requires some understanding of the asynchronous exception behaviors described in [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839](#).

[AArch32 state exception descriptions on page G1-3849](#) then describes each exception.

G1.12.1 Exception vectors and the exception base address

When an exception is taken, PE execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception. The vectors for the different types of exception form a *vector table*.

———— Note ————

There are significant differences in the sets of exception vectors for exceptions taken to an Exception level that is using AArch32 and for exceptions taken to an Exception level that is using AArch64. This part of this manual describes only how exceptions are taken to an Exception level that is using AArch32. So, for example, when executing at EL1 or EL0, an exception might be generated that must be taken to EL3. In this case:

- If EL3 is using AArch32 then the exception is taken as described in this chapter, using the exception vectors described in this section.
- If EL3 is using AArch64 then the exception is taken as described in [Chapter D1 The AArch64 System Level Programmers' Model](#) using the exception vectors described in [Exception vectors on page D1-1522](#).

AArch32 state defines exception vector tables for exceptions taken to EL2 and EL3 when those Exception levels are using AArch32. Those vector tables are not used when the corresponding Exception levels are using AArch64.

A set of exception vectors for an Exception level that is using AArch32 comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form an AArch32 *vector table*.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented Exception levels, as follows:

Implementation that does not include EL3

Any implementation that does not include EL3 must include the following AArch32 vector table if EL1 can use AArch32:

- An exception table for exceptions taken to EL1 modes other than System mode. This is the EL1 vector table, and is in the address space of the PL1&0 translation regime.

———— **Note** —————

Exceptions cannot be taken to System mode.

For this vector table, the **VBAR** holds the exception base address.

Implementation that includes EL2

Any implementation that includes EL2 must include the following additional AArch32 vector table if EL2 can use AArch32:

- An exception table for exceptions taken to Hyp mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.

For this vector table, **HVBAR** holds the exception base address.

Implementation that includes EL3

Any implementation that includes EL3 must include the following AArch32 vector tables:

- If EL3 can use AArch32, a vector table for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, **MVBAR** holds the exception base address.

- If Secure EL1 can use AArch32, a vector table for exceptions taken to Secure privileged modes other than Monitor mode and System mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.

For this vector table, the Secure **VBAR** holds the exception base address.

- If Non-secure EL1 can use AArch32, a vector table for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For this vector table, the Non-secure **VBAR** holds the exception base address.

The following subsections give more information:

- [The vector tables and exception offsets.](#)
- [Pseudocode determination of the exception base address on page G1-3816.](#)

The vector tables and exception offsets

Table G1-6 on page G1-3814 defines the AArch32 vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to modes other than Monitor mode, Hyp mode, System mode, and User mode. [Table G1-7 on page G1-3814](#) shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

———— **Note** —————

Exceptions cannot be taken to System mode or User mode.

For more information about determining the mode to which an exception is taken, see [PE mode for taking exceptions on page G1-3822](#).

When EL2 is using AArch32, it provides a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see [interrupt Offsets of AArch32 exceptions provided by EL2 on page G1-3815](#).

Table G1-6 The AArch32 vector tables

| Offset | Vector tables | | | |
|--------|--|----------------------|-----------------------|-------------------------|
| | Hyp ^a | Monitor ^b | Secure ^c | Non-secure ^c |
| 0x00 | Not used | Not used | Not used ^d | Not used |
| 0x04 | Undefined Instruction, from Hyp mode | Monitor Trap | Undefined Instruction | Undefined Instruction |
| 0x08 | Hypervisor Call, from Hyp mode | Secure Monitor Call | Supervisor Call | Supervisor Call |
| 0x0C | Prefetch Abort, from Hyp mode | Prefetch Abort | Prefetch Abort | Prefetch Abort |
| 0x10 | Data Abort, from Hyp mode | Data Abort | Data Abort | Data Abort |
| 0x14 | Hyp Trap, or Hyp mode entry ^e | Not used | Not used | Not used |
| 0x18 | IRQ interrupt | IRQ interrupt | IRQ interrupt | IRQ interrupt |
| 0x1C | FIQ interrupt | FIQ interrupt | FIQ interrupt | FIQ interrupt |

- a. Non-secure state only. Implemented only if the implementation includes EL2 and EL2 can use AArch32.
- b. Secure state only. Implemented only if the implementation includes EL3 and EL3 can use AArch32.
- c. If the implementation does not include EL3 then there is a single vector table for exceptions taken to EL1 when EL1 is using AArch32. That table holds the vectors shown in the Secure column of this table
- d. In previous versions of the architecture, this entry has been used for the Reset vector, meaning the address at which execution starts on coming out of reset. In ARMv8, the AArch32 Reset vector is IMPLEMENTATION DEFINED. An implementation might use this vector table entry to hold the Reset vector.
- e. See [Use of offset 0x14 in the Hyp vector table on page G1-3815](#).

Table G1-7 Modes for taking the exceptions shown in the Secure or Non-secure vector table

| Exception | Mode taken to |
|-----------------------|---------------|
| Undefined Instruction | Undefined |
| Supervisor Call | Supervisor |
| Prefetch Abort | Abort |
| Data Abort | Abort |
| IRQ interrupt | IRQ |
| FIQ interrupt | FIQ |

For more information about use of the vector tables see [Overview of exception entry on page G1-3819](#).

Interrupt Offsets of AArch32 exceptions provided by EL2

EL2 provides the following exceptions. When EL2 is using AArch32, these exceptions are taken to Hyp mode, and the PE enters the handlers for these exceptions using the following vector table entries shown in [Table G1-6 on page G1-3814](#):

Hypervisor Call

If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see [Use of offset 0x14 in the Hyp vector table](#).

Hyp Trap Shown explicitly in the Hyp mode vector table.

Virtual Abort Entered through the Data Abort vector in the Non-secure vector table.

Virtual IRQ Entered through the IRQ vector in the Non-secure vector table.

Virtual FIQ Entered through the FIQ vector in the Non-secure vector table.

———— Note —————

[Virtual exceptions when an implementation includes EL2 on page G1-3839](#) gives more information about the virtual exceptions.

Use of offset 0x14 in the Hyp vector table

The vector at offset 0x14 in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for any Hypervisor Call exception that is taken from a mode other than Hyp mode.
- Used for any Supervisor Call exception that is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Undefined Instruction that is taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
- Used for any Prefetch Abort exception that is:
 - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
 - Generated by a Debug exception from Non-secure state when the value of [HDCR.TDE](#) is 1.
 - Generated by a stage 2 abort on an address translation instruction.
- Used for any Data Abort exception that is:
 - Taken from Non-secure User mode when the value of [HCR.TGE](#) is 1.
 - Generated by an SError interrupt from Non-secure state when the value of [HCR.AMO](#) is 1.
 - Generated by a Watchpoint exception from Non-secure state when the value of [HDCR.TDE](#) is 1.
 - Generated by a stage 2 abort on an address translation operation.

———— Note —————

Offset 0x14 is never used for the following exceptions:

- IRQ exceptions.
- Virtual IRQ exceptions.
- FIQ exceptions.
- Virtual FIQ exceptions.

Virtual exceptions are never taken to Hyp mode.

For more information, see [PE mode for taking exceptions on page G1-3822](#).

Pseudocode determination of the exception base address

For an exception taken to a PL1 mode, the `ExcVectorBase()` function determines the exception base address.

The `ExcVectorBase()` function is defined in [Chapter J1 ARMv8 Pseudocode](#).

Note

The PL1 modes to which exceptions can be taken are Supervisor mode, Undefined mode, Abort mode, IRQ mode, and FIQ mode. In Non-secure state, and in Secure state when EL3 is using AArch64, these are EL1 modes. However, in Secure state when EL3 is using AArch32, these are EL3 modes. For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#).

G1.12.2 Exception prioritization for exceptions taken to AArch32 state

The following sections describe the ARMv8 requirements for the prioritization of synchronous exceptions, and the limits on when asynchronous exceptions can be taken:

- [Synchronous exception prioritization for exceptions taken to AArch32 state](#).
- [Architectural requirements for taking asynchronous exceptions on page G1-3818](#).

See also:

- [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#), for information about:
 - The prioritization of aborts on a single memory access in a VMSA implementation.
 - The prioritization of exceptions generated during address translation.
- [Debug state entry and debug event prioritization on page H2-4847](#) for information about the relative prioritization of exceptions and the debug events that cause entry to Debug state.

Synchronous exception prioritization for exceptions taken to AArch32 state

In principle, any single instruction can generate a number of different synchronous exceptions, between the fetching of the instruction, its decode, and eventual execution. This section describes the prioritization of such exceptions when they are taken to an Exception level that is using AArch32.

Note

- An exception that is taken to an Exception level that is using AArch32 must have been taken from an Exception level that is using AArch32.
 - The priority numbering in this list only shows the relative priorities of exceptions taken to an Exception level that is using AArch32. This numbering has no global significance and, for example, does not correlate with the equivalent AArch32 list in [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#).
-

For an exception that is taken to an Exception level that is using AArch32, exceptions are prioritized as follows, where 1 is the highest priority.

1. PC alignment fault exceptions. A PC alignment fault exception can only be taken to an Exception level that is using AArch32 as a result of:
 - The CONSTRAINED UNPREDICTABLE handling of a branch to an unaligned address, see [Branching to an unaligned PC on page K1-5458](#).
 - Exiting from Debug state to AArch32 specifying an unaligned PC value, see [Exiting Debug state on page H2-4880](#).

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, see [Prefetch Abort exception reporting a PC alignment fault exception on page G1-3857](#).

2. Prefetch Abort exceptions. See [Prefetch Abort exception on page G1-3856](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#).
3. Breakpoint exceptions or Address Matching Vector Catch exceptions. See:
 - [Breakpoint exceptions on page G2-3938](#).
 - [Vector Catch exceptions on page G2-3975](#).

———— **Note** —————

An Exception Trapping Vector Catch exception is generated on exception entry for an exception that has been prioritized as described in this section. This means that it does not have its own entry in this list.

4. Illegal Execution state exceptions. See [The Illegal Execution state exception on page G1-3837](#).
5. Exceptions taken from EL1 to EL2 because of one of the following configuration settings:
 - [HSTR.Tn](#).
 - [HCR.TIDCP](#).
6. Undefined Instruction exceptions that occur as a result of one or more of the following:
 - An attempt to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation.
 - An attempt to execute an instruction that is defined never to be accessible at the current Exception level regardless of any enables or traps.
 - Debug state execution of an instruction encoding that is unallocated in Debug state.
 - Non-debug state execution of an instruction encoding that is unallocated in Non-debug state.
 - Execution of an HVC instruction, when HVC instructions are disabled by [SCR.HCE](#) or [HCR.HCD](#).
 - Execution of an HLT instruction when HLT instructions are disabled by [EDSCR.HDE](#).
 - In Debug state:
 - Execution of a DCPS1 instruction in Non-secure EL0 when [HCR.TGE](#) is 1.
 - Execution of a DCPS2 instruction in EL1 or EL0 when [SCR.NS](#) is 0 or when EL2 is not implemented.
 - Execution of a DCPS3 instruction when [EDSCR.SDD](#) is 1 or when EL3 is not implemented.
 - When the value of [EDSCR.SDD](#) is 1, execution in EL2, EL1, or EL0 of an instruction that is trapped to EL3.
 - Execution of an instruction that is UNDEFINED as a result of any of:
 - Being in an IT block when [SCTLR.ITD](#) is 1, or when [HSCTLR.ITD](#) is 1.
 - Executing a SETEND instruction when [SCTLR.SED](#) is 1, or when [HSCTLR.SED](#) is 1.
 - Executing a [CP15DMB](#), [CP15DSB](#), or [CP15ISB](#) barrier instruction when [SCTLR.CP15BEN](#) is 0, or when [HSCTLR.CP15BEN](#) is 0.

See [Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-3888](#) and [Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-3897](#).
 - Execution of an instruction that is UNDEFINED because at least one of [FPSCR.{Stride, Len}](#) is nonzero, when programming these bits to nonzero values is supported. See [Floating-point exception traps on page G1-3883](#).
7. Exceptions taken to EL1, or taken to EL2 because the value of [HCR.TGE](#) is 1, that are generated because of configurable access to instructions, and that are not covered by any of priorities 1-6.
8. Exceptions taken from EL0 to EL2 because of one of the following configuration settings:
 - [HSTR.Tn](#).
 - [HCR.TIDCP](#).
9. Exceptions taken to EL2 because of configuration settings in the [HCPTR](#).

10. Exceptions taken to EL2 because of one of the following configuration settings:
 - Any setting in [HCR](#), other than the TIDCP bit.
 - Any setting in [CNTHCTL](#).
 - Any setting in [HDCR](#).
11. Exceptions taken to EL2 because of configurable access to instructions, and that are not covered by any of priorities [1 - 10](#).
12. Exceptions caused by the SMC instruction being UNDEFINED because the value of [SCR.SCD](#) is 1.
13. Exceptions caused by the execution of an Exception generating instruction, SVC, HVC, SMC, or BKPT.
14. Exceptions taken to EL3 because of configuration settings in the [SDCR](#). These might be taken from EL0, EL1, or EL2.
15. Exceptions taken to EL3 because of configurable access to instructions, and that are not covered by any of priorities [1 - 14](#).
16. Trapped floating-point exceptions, if supported. See [Floating-point exception traps on page G1-3883](#).
17. Data Abort exceptions other than a Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk. That is, any Data Abort exception that is not covered by item [19](#). See [Data Abort exception on page G1-3859](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item [19](#).
18. Watchpoint exceptions. See [Watchpoint exceptions on page G2-3961](#).
19. Data Abort exception generated by a Synchronous external abort that was not generated by a translation table walk, see [External aborts on page G3-4014](#). It is IMPLEMENTATION DEFINED whether Synchronous external aborts are prioritized here or as item [17](#).

For items [17 - 19](#), if an instruction results in more than one single-copy atomic memory access, the prioritization between synchronous exceptions generated on each of those different memory accesses is not defined by the architecture.

———— **Note** —————

Exceptions generated by a translation table walk are reported and prioritized as either a Prefetch Abort exception, priority [2](#) in this list, or a Data Abort exception, priority [17](#) in this list. See also [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#).

Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken. The prioritization of asynchronous exceptions, including virtual asynchronous exceptions, is IMPLEMENTATION DEFINED.

An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked:

- Execution of an ISB instruction that does not fail its condition code check.
- Exception entry.
- Exception return.
- Exit from Debug state.

Note

- If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.
- The [ISR](#) identifies any pending asynchronous exceptions.
- Interrupts are masked when the PE is in Debug state, and therefore this list of context synchronizing events does not include the DCPS and DRPS instructions.

In the absence of a specific requirement to take an asynchronous exception, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

Note

The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

If an unmasked interrupt was pending but is changed to not pending before it is taken, then the architecture permits the interrupt to be taken, but does not require this to happen. If the interrupt is taken then it must be taken before the first [Context synchronization event](#) after the interrupt was changed to not pending.

[PSTATE](#) includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, although when the PE is in Non-secure state other controls can modify the effect of these bits. For more information, see [Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839](#).

Taking an exception sets an exception-dependent subset of these mask bits.

Note

In some contexts, the [PSTATE](#).{A, I, F} bits mask the taking of asynchronous exceptions. The way these are set on exception entry, described in [PSTATE.{A, I, F, M} values on exception entry on page G1-3827](#), can prevent an exception handler being interrupted by an asynchronous exception.

G1.12.3 Overview of exception entry

There are some significant differences between the handling of exceptions taken to Hyp mode and exceptions taken to other modes. Because Hyp mode is the EL2 mode, this means that the following descriptions sometimes distinguish between the *EL2 mode* and the *non-EL2 modes*.

On taking an exception to an Exception level that is using AArch32:

1. The hardware determines the mode to which the exception must be taken, see [PE mode for taking exceptions on page G1-3822](#).
2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
 - The exception type.
 - Whether the exception is taken to the EL2 mode or to a non-EL2 mode.
 - For some exceptions taken to non-EL2 modes, the instruction set state when the exception was taken.

Where the link value is saved depends on whether the exception is taken to the EL2 mode.

For more information see [Link values saved on exception entry on page G1-3821](#).

3. The value of [PSTATE](#) is saved in the [SPSR](#) for the mode to which the exception must be taken. The value saved in [SPSR.IT\[7:0\]](#) is always correct for the preferred return address.

4. In an implementation that includes EL3, when EL3 is using AArch32:
 - If the exception is taken from Monitor mode, **SCR.NS** is cleared to 0.
 - Otherwise, taking the exception leaves **SCR.NS** unchanged.
 When EL3 is using AArch64, Monitor mode is not available.
5. **PSTATE** is updated with new context information for the exception handler. This includes:
 - Setting **PSTATE.M** to the PE mode to which the exception is taken.
 - Setting the appropriate **PSTATE** mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
 - Setting the instruction set state to the state required for exception entry.
 - Setting the endianness to the required value for exception entry.
 - Clearing the **PSTATE.IT[7:0]** bits to 0.
 For more information, see [PE state on exception entry on page G1-3826](#).
6. The appropriate exception vector is loaded into the PC, see [Exception vectors and the exception base address on page G1-3812](#).
7. Execution continues from the address held in the PC.

For an exception taken to a non-EL2 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same Exception level and in the same Security state, and can use the CPS instruction to change mode. For more information about the instructions, see [SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-3018](#) and [CPS, CPSID, CPSIE on page F5-2645](#).

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the PE state changes on taking that exception. [Table G1-8](#) gives an index to these descriptions:

Table G1-8 Pseudocode descriptions of exception entry for exceptions taken to AArch32 state

| Exception | Description of exception entry |
|-----------------------|---|
| Reset | Pseudocode descriptions of reset on page G1-3871 |
| Undefined Instruction | Pseudocode description of taking the Undefined Instruction exception on page G1-3851 |
| Hyp Trap | Pseudocode description of taking the Hyp Trap exception on page G1-3853 |
| Monitor Trap | Pseudocode description of taking the Monitor Trap exception on page G1-3852 |
| Supervisor Call | Pseudocode description of taking the Supervisor Call exception on page G1-3854 |
| Secure Monitor Call | Pseudocode description of taking the Secure Monitor Call exception on page G1-3855 |
| Hypervisor Call | Pseudocode description of taking the Hypervisor Call exception on page G1-3856 |
| Prefetch Abort | Pseudocode description of taking the Prefetch Abort exception on page G1-3858 |
| Data Abort | Pseudocode description of taking the Data Abort exception on page G1-3861 |
| Virtual Abort | Pseudocode description of taking the Virtual SError interrupt exception on page G1-3862 |
| IRQ | Pseudocode description of taking the IRQ exception on page G1-3864 |
| Virtual IRQ | Pseudocode description of taking the Virtual IRQ exception on page G1-3865 |
| FIQ | Pseudocode description of taking the FIQ exception on page G1-3866 |
| Virtual FIQ | Pseudocode description of taking the Virtual FIQ exception on page G1-3867 |

The following sections give more information about the PE state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- [PE mode for taking exceptions on page G1-3822.](#)
- [PE state on exception entry on page G1-3826.](#)

Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the preferred return address for the exception, as shown in [Table G1-9](#):

Table G1-9 Exception return addresses for exceptions taken to AArch32 state

| Exception | Preferred return address | Taken to a mode at |
|----------------------------|--|---|
| Undefined Instruction | Address of the UNDEFINED instruction | Non-EL2 ^a , or EL2 ^c |
| Hyp Trap | Address of the trapped instruction | EL2 only ^c |
| Monitor Trap | Address of the trapped instruction | EL3 only |
| Supervisor Call | Address of the instruction after the SVC instruction | Non-EL2 ^a or EL2 ^c |
| Secure Monitor Call | Address of the instruction after the SMC instruction | EL3 ^b , and only in Secure state |
| Hypervisor Call | Address of the instruction after the HVC instruction | EL2 only ^c |
| Prefetch Abort | Address of aborted instruction fetch | Non-EL2 ^a or EL2 ^c |
| Data Abort | Address of instruction that generated the abort | Non-EL2 ^a or EL2 ^c |
| Virtual Abort | Address of next instruction to execute | EL1, and only in Non-secure state |
| IRQ or FIQ | Address of next instruction to execute | Non-EL2 ^a or EL2 ^c |
| Virtual IRQ or Virtual FIQ | Address of next instruction to execute | EL1, and only in Non-secure state |

- EL1 if the exception is taken to a Non-secure mode, or is taken to a Secure mode when EL3 is using AArch64. EL3 if the exception is taken to a Secure mode when EL3 is using AArch64.
- A Secure Monitor Call exception is taken to EL3, and therefore is taken to AArch32 state only if EL3 is using AArch32, in which case it is taken to Monitor mode.
- EL2 is implemented only in Non-secure state. Therefore, an exception can be taken to EL2 mode only if it is taken from Non-secure state.

Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by the Exception level from which the exception was taken.

The link value saved, and where it is saved, depend on whether the exception is taken to a non-EL2 mode, or to an EL2 mode, as follows:

Exception taken to a non-EL2 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as [Table G1-10](#) shows:

Table G1-10 Offsets applied to Link value for exceptions taken to non-EL2 modes

| Exception | Offset, for PE state of: | |
|----------------------------|--------------------------|------|
| | A32 | T32 |
| Undefined Instruction | +4 | +2 |
| Monitor Trap | +4 | +2 |
| Supervisor Call | None | None |
| Secure Monitor Call | None | None |
| Prefetch Abort | +4 | +4 |
| Data Abort | +8 | +8 |
| Virtual Abort | +8 | +8 |
| IRQ or FIQ | +4 | +4 |
| Virtual IRQ or Virtual FIQ | +4 | +4 |

Exception taken to an EL2 mode

The link value is saved in the [ELR_hyp](#) Special-purpose register.

The saved link value is the preferred return address for the exception, as shown in [Table G1-9 on page G1-3821](#), with no offset.

G1.12.4 PE mode for taking exceptions

The following principles determine the Exception level to which an exception is taken, and if that Exception level is using AArch32, the PE mode to which the exception is taken:

- An exception cannot be taken to the EL0 mode.
- An exception is taken either:
 - To the Exception level at which the PE was executing when it took the exception.
 - To a higher Exception level.

This means that, in Secure state:

- When EL3 is using AArch32, an exception is always taken to an EL3 mode.
- When EL3 is using AArch64, an exception that is taken to AArch32 state is taken to an EL1 mode.
- Configuration options and other features provided by EL2 and EL3 can determine the mode to which some exceptions are taken, as follows:

In an implementation that does not include EL2 or EL3

An exception is always taken to the default mode for that exception.

In an implementation that includes EL3

A Secure Monitor Call exception is always taken to EL3. This means:

- If EL3 is using AArch32 the exception is taken to Secure Monitor mode.
- If EL3 is using AArch64 then executing the instruction generates an exception that is taken to EL3, see *Execution of an SMC instruction from a privileged Exception level that is using AArch32* on page G1-3824.

IRQ, FIQ, and External abort exceptions can be configured to be taken to EL3. Therefore, if EL3 is using AArch32 the exceptions are taken to Secure Monitor mode.

When EL3 is using AArch32, a Monitor Trap exception is taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception. As described in *Security state, Exception levels, and AArch32 execution privilege* on page G1-3792, this means it is taken to:

- An EL3 mode other than Monitor mode if EL3 is using AArch32.
- An EL1 mode if EL3 is using AArch64.

If the implementation does not include EL2, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state to the default mode for that exception. The default mode will be an EL1 mode.

In an implementation that includes EL2

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- If the exception is taken from Hyp mode then it is taken to Hyp mode.
- Otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode* on page G1-3824, or taken to the default mode for the exception.

————— Note —————

- Hyp mode is the EL2 mode. The other modes to which an exception can be taken in Non-secure state are EL1 modes.
- EL2 has no effect on the handling of exceptions taken from Secure state.

Table G1-7 on page G1-3814 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page G1-3841 describes the exception routing controls provided by EL2 and EL3.

Routing of aborts taken to AArch32 state on page G4-4110 gives more information about the modes to which memory aborts are taken.

The possible modes for taking each exception on page G1-3825 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- That include neither EL2 nor EL3.
- That include EL2 but not EL3
- That do not include EL2 but include EL3
- That include both EL2 and EL3.

Exceptions taken to Hyp mode

In an implementation that includes EL2 and EL3, when EL2 is using AArch32:

- Any exception taken from Hyp mode, that is not routed to EL3 by the controls described in [Asynchronous exception routing controls on page G1-3841](#), is taken to Hyp mode.
- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
 - An abort that [Routing of aborts taken to AArch32 state on page G4-4110](#) identifies as taken to Hyp mode.
 - A Hyp Trap exception, see [EL2 configurable controls on page G1-3894](#).
 - A Hypervisor Call exception. This is generated by executing an HVC instruction in a Non-secure mode.
 - An SError interrupt exception, IRQ exception or FIQ exception that is not routed to EL3 but is explicitly routed to Hyp mode, as described in [Asynchronous exception routing controls on page G1-3841](#).
 - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure EL0 mode and explicitly routed to Hyp mode, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

Note

A synchronous external abort can be routed to Hyp mode only if it is not routed to EL3.

- A debug exception that is explicitly routed to Hyp mode as described in [Routing debug exceptions to EL2 on page G1-3833](#).

Note

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure EL1 mode.

Security behavior in Exception levels using AArch32 when EL3 is using AArch64

As described in [The ARMv8-A security model on page G1-3789](#), when EL3 is using AArch64, lower Exception levels, in either Security state, can be using AArch32. This means software executing in those Exception levels might try to access AArch32 security features that are not available. The following subsections describe the associated behaviors:

- [Execution of an SMC instruction from a privileged Exception level that is using AArch32](#)
- [Non-secure reads of the NSACR](#)
- [Secure EL1 operations when Secure EL1 is using AArch32 on page G1-3825](#)

Execution of an SMC instruction from a privileged Exception level that is using AArch32

When EL3 is using AArch64, an SMC instruction executed from Secure or Non-secure EL1 using AArch32, or from Non-secure EL2 using AArch32 when the value of HCR.TSC is 0, generates an exception that is taken to EL3. The exception syndrome is reported with an EC value of 0x13, SMC instruction executed in AArch32 state, see [Exception from SMC instruction execution in AArch32 state on page D1-1531](#).

Non-secure reads of the NSACR

The NSACR is defined as being RO from Non-secure PE modes other than User mode. When EL3 is using AArch64, a read of the NSACR returns a fixed value of 0x00000C00 in the following cases:

- If the read is from a Non-secure EL1 mode when EL1 is using AArch32.
- If the read is from Hyp mode when EL2 is using AArch32.

Secure EL1 operations when Secure EL1 is using AArch32

When Secure EL1 is using AArch32 and EL3 is using AArch64:

- Any of the following operations performed in a Secure EL1 mode is trapped to Secure EL3:
 - A read or write of any of the [SCR](#), [NSACR](#), [MVBAR](#), and [SDCR](#).
 - Executing any of the [ATS12NSO**](#) instructions described in [ATS12NSOxx, Address translation stages 1 and 2, Non-secure state only](#) on page G4-4143.
 - Executing an SRS instruction that would use [SP_mon](#), see [SRS, SRSDA, SRSDB, SRSIA, SRSIB](#) on page F5-3018.
 - Executing an MRS (Banked register) or MSR (Banked register) instruction that would access [SPSR_mon](#), [SP_mon](#), or [LR_mon](#), see [MRS \(Banked register\)](#) on page F5-2832 and [MSR \(Banked register\)](#) on page F5-2836.

For more information about these traps, including the associated exception syndromes, see [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32](#) on page D1-1590.

- Writes to the [CNTFRQ](#) register are UNDEFINED.
- Any attempt to move into Monitor mode, either by an exception return or by executing a CPS or MSR instruction, is treated as an illegal operation and is handled as described in [Illegal return events from AArch32 state](#) on page G1-3835.

————— **Note** —————

This functionality supports a usage model where:

- EL3 uses AArch64.
- Secure software executed in Secure EL1 using AArch32 and Secure EL0 using AArch32.
- The Non-secure state uses AArch64.

The possible modes for taking each exception

Each of the exception descriptions in [AArch32 state exception descriptions](#) on page G1-3849 includes a subsection that describes the modes to which each exception can be taken. Those subsections are:

- [The PE mode to which the Undefined Instruction exception is taken](#) on page G1-3850.
- [The PE mode to which the Hyp Trap exception is taken](#) on page G1-3852.
- [The PE mode to which the Monitor Trap exception is taken](#) on page G1-3852.
- [The PE mode to which the Supervisor Call exception is taken](#) on page G1-3853.
- [The PE mode to which the Secure Monitor Call exception is taken](#) on page G1-3855.
- [The PE mode to which the Hypervisor Call exception is taken](#) on page G1-3855.
- [The PE mode to which the Prefetch Abort exception is taken](#) on page G1-3858.
- [The PE mode to which the Data Abort exception is taken](#) on page G1-3860.
- [The PE mode to which the Virtual SError interrupt exception is taken](#) on page G1-3862.
- [The PE mode to which the physical IRQ exception is taken](#) on page G1-3863.
- [The PE mode to which the Virtual IRQ exception is taken](#) on page G1-3865.
- [The PE mode to which the physical FIQ exception is taken](#) on page G1-3866.
- [The PE mode to which the Virtual FIQ exception is taken](#) on page G1-3867.

These descriptions also show the vector offset for the exception entry for each mode. These descriptions assume that all Exception levels are using AArch32, meaning:

- [HCR](#), rather than [HCR_EL2](#), controls the routing of exceptions to EL2.
- [SCR](#), rather than [SCR_EL3](#), controls the routing of exceptions to EL3.

For more information about:

- Vector offsets, see [Exception vectors and the exception base address](#) on page G1-3812.
- The routing of synchronous external aborts or SError, IRQ, and FIQ interrupt exceptions, and the virtual exceptions, see [Asynchronous exception routing controls](#) on page G1-3841.

UNPREDICTABLE cases when the value of HCR.TGE is 1

When the value of HCR.TGE is 1, exceptions that would otherwise be taken to EL1 are, instead, routed to EL2, see [Routing exceptions from Non-secure EL0 to EL2](#) on page G1-3828. Related to this, when the value of HCR.TGE is 1, execution in a Non-secure EL1 mode is UNPREDICTABLE. ARMv8 does not constrain this UNPREDICTABLE behavior, but in ARMv8 software that follows the ARM recommendations cannot get to this state. When following the ARM recommendations, any attempt to move to a Non-secure EL1 mode when the value of HCR.TGE is 1 is either:

- An illegal exception return, see [Illegal return events from AArch32 state](#) on page G1-3835.
- An illegal PE mode change, see [Illegal changes to PSTATE.M](#) on page G1-3809.

G1.12.5 PE state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as [Table G1-8](#) on page G1-3820 shows. The following sections describe the PE state changes on entering an exception, for different implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- [Instruction set state on exception entry.](#)
- [PSTATE.E value on exception entry](#) on page G1-3827.
- [PSTATE.{A, I, F, M} values on exception entry](#) on page G1-3827.

———— **Note** —————

The descriptions in these sections assume that EL2 and EL3, that control some aspects of the routing of exceptions taken from EL1 or EL0, are both using AArch32. If this is not the case:

- If EL2 is using AArch64:
 - Controls shown as provided by the [HSCTLR](#) are provided by the [SCTLR_EL2](#).
 - Controls shown as provided by the [HCR](#) are provided by the [HCR_EL2](#).
- If EL3 is using AArch64, controls shown as provided by the [SCR](#) are provided by the [SCR_EL3](#).

Instruction set state on exception entry

Exception handlers can execute in either T32 state or A32 state. On exception entry, [PSTATE.T](#) is set to the required value, as determined by [SCTLR.TE](#) or [HSCTLR.TE](#), depending on the mode the exception is taken to. [Table G1-11](#) shows this:

Table G1-11 PSTATE.T bit value on exception entry

| Mode to which exception is taken | HSCTLR.TE | SCTLR.TE | PSTATE.T | Exception handler state |
|----------------------------------|-----------|----------|----------|-------------------------|
| Not Hyp mode | x | 0 | 0 | A32 |
| | | 1 | 1 | T32 |
| Hyp mode | 0 | x | 0 | A32 |
| | 1 | x | 1 | T32 |

When an implementation includes EL3 and EL3 is using AArch32, **SCTLR** is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a PE mode other than Hyp mode, the **SCTLR**.TE bit for the Security state to which the exception is taken determines the instruction set state for the exception handler. This means the instruction set state in which an exception handler might depending on the Security state to which the exception is taken.

PSTATE.E value on exception entry

PSTATE.E controls the load and store endianness for data handling. [Table G1-12](#) show the value to which this bit is set on exception entry:

Table G1-12 PSTATE.E value on exception entry

| Exception mode | HSCTLR.EE | SCTLR.EE | Endianness for data loads and stores | PSTATE.E |
|--------------------------|-----------|----------|--------------------------------------|----------|
| Secure or Non-secure EL1 | x | 0 | Little-endian | 0 |
| | | 1 | Big-endian | 1 |
| Hyp | 0 | x | Little-endian | 0 |
| | | 1 | Big-endian | 1 |

For more information, see the bit description in *SPSR format for exceptions taken to AArch32 state on page G1-3804*.

PSTATE.{A, I, F, M} values on exception entry

On exception entry, **PSTATE**.M is set to the value for the mode to which the exception is taken, as described in *PE mode for taking exceptions on page G1-3822*.

[Table G1-13 on page G1-3828](#) shows the cases where **PSTATE**.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and Security state to which an exception is taken. If the table entry for a particular mode and Security state does not define a value for a **PSTATE**.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, EL2 not implemented* column applies to exceptions taken to Non-secure state in an implementation that includes EL3 but does not include EL2.
- The *All others* column applies to:
 - Exceptions taken to Secure state.
 - Implementations that do not include the EL3.

- Exceptions taken to Non-secure state in an implementation that includes EL2.

Table G1-13 **PSTATE.{A, I, F} values on exception entry**

| PE mode exception is taken to | Security state | |
|-------------------------------|--|---|
| | Non-secure | Secure |
| Hyp | If <code>SCR.EA==0</code> then <code>PSTATE.A</code> is set to 1 If <code>SCR.IRQ==0</code> then <code>PSTATE.I</code> is set to 1 If <code>SCR.FIQ==0</code> then <code>PSTATE.F</code> is set to 1 | - |
| Monitor | - | <code>PSTATE.A</code> is set to 1 <code>PSTATE.I</code> is set to 1 <code>PSTATE.F</code> is set to 1 |
| FIQ | <code>PSTATE.A</code> is set to 1 <code>PSTATE.I</code> is set to 1 <code>PSTATE.F</code> is set to 1 | <code>PSTATE.A</code> is set to 1 <code>PSTATE.I</code> is set to 1 <code>PSTATE.F</code> is set to 1 |
| IRQ, Abort | <code>PSTATE.A</code> is set to 1 <code>PSTATE.I</code> is set to 1 | <code>PSTATE.A</code> is set to 1 <code>PSTATE.I</code> is set to 1 |
| Undefined, Supervisor | <code>PSTATE.I</code> is set to 1 | <code>PSTATE.I</code> is set to 1 |

Asynchronous exception behavior for exceptions taken from AArch32 state on page G1-3839 describes how, in some situations, the `PSTATE.{A, I, F}` bits mask the taking of SError interrupts, IRQ interrupts, and FIQ interrupts.

G1.12.6 Routing exceptions from Non-secure EL0 to EL2

———— **Note** ————

The routing control described in this section permits a Non-secure state usage model where applications execute in User mode under a hypervisor, that executes in Hyp mode, without a Guest OS running at Non-secure EL1. This control applies when either:

- EL2 is using AArch32 and the value of `HCR.TGE` is 1.
- EL2 is using AArch64 and the value of `HCR_EL2.TGE` is 1.

If the PE is in Non-secure User mode, any exception that would otherwise be taken to Non-secure EL1 is taken to EL2 if either:

- EL2 is using AArch32 and the value of `HCR.TGE` is 1.
In this case the exception is taken to Hyp mode, instead of to the default Non-secure mode for handling the exception. For more information see *Exception reporting when `HCR.TGE` routes an exception to EL2 using AArch32 on page G1-3829*.
- EL2 is using AArch64 and the value of `HCR_EL2.TGE` is 1.

Any exception that is routed to Secure Monitor mode or to EL3 using AArch64 is unaffected by the value of `HCR.TGE` or `HCR_EL2.TGE`.

When TGE routing from Non-secure EL0 applies:

- When EL2 is using AArch32:
 - The **SCTLR.M** bit is treated as 0 for all purposes other than a direct read of the **SCTLR** register.
 - Each of the **HCR.{FMO, IMO, AMO}** bits is treated as 1 for all purposes other than a direct read of the **HCR** register
 - Each of the **HDCR.{TDE, TDA, TDRA, TDOSA}** bits is treated as 1 for all purposes other than a direct read of the **HDCR** register.

———— **Note** —————

When EL2 is using AArch64:

- The **SCTLR_EL2.M** bit is treated as 0 for all purposes other than a direct read of the register.
 - The **HCR_EL2.{FMO, IMO, AMO}** bits are treated as 1 for all purposes other than a direct read of the register.
 - The **MDCR_EL2.{TDE, TDA, TDRA, TDOSA}** bits are treated as 1 for all purposes other than a direct read of the register.
-
- An exception return to EL1 is treated as an illegal exception return, see *Illegal return events from AArch32 state on page G1-3835*.
 - All virtual interrupts, including any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts, are disabled.

Exception reporting when HCR.TGE routes an exception to EL2 using AArch32

The following sections give more information about the behavior of synchronous exceptions that are routed to Hyp mode because the value of **HCR.TGE** is 1:

- *Undefined Instruction exception, when the value of HCR.TGE is 1.*
- *Supervisor Call exception, when the value of HCR.TGE is 1.*
- *Abort exceptions, when the value of HCR.TGE is 1 on page G1-3830.*
- *Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1 on page G1-3830.*

Undefined Instruction exception, when the value of HCR.TGE is 1

When **HCR.TGE** is set to 1, if the PE is executing in Non-secure User mode and attempts to execute an UNDEFINED instruction, it takes the Hyp Trap exception, instead of an Undefined Instruction exception. On taking the Hyp Trap exception, the **HSR** reports an unknown reason for the exception, using the EC value 0x00. For more information see *Use of the HSR on page G4-4137*.

Supervisor Call exception, when the value of HCR.TGE is 1

When **HCR.TGE** is set to 1, if the PE executes an SVC instruction in Non-secure User mode, the Supervisor Call exception generated by the instruction is taken to Hyp mode.

The **HSR** reports that entry to Hyp mode was because of a Supervisor Call exception, and:

- If the SVC is unconditional, takes for the **imm16** value in the **HSR**:
 - A zero-extended 8-bit immediate value for the T32 SVC instruction.

———— **Note** —————

The only T32 encoding for SVC is a 16-bit instruction encoding.

- The bottom16 bits of the immediate value for the A32 SVC instruction.
- If the SVC is conditional, the **imm16** value in the **HSR** is UNKNOWN.

If the SVC is conditional, the PE takes the exception only if the instruction passes its condition code check.

The **HSR** reports the exception as a Supervisor Call exception taken to Hyp mode, using the EC value 0x11. For more information, see *Use of the HSR on page G4-4137*.

———— **Note** ————

The effect of setting [HCR.TGE](#) to 1 is to route the Supervisor Call exception to Hyp mode, not to trap the execution of the SVC instruction. This means that the preferred return address for the exception, when routed to Hyp mode in this way, is the instruction after the SVC instruction.

Abort exceptions, when the value of HCR.TGE is 1

When the value of [HCR.TGE](#) is 1, if the PE is executing in Non-secure User mode then any abort exception that is not routed to Secure Monitor mode or to EL3 using AArch64 generates an exception that is taken as a Hyp Trap exception. Where an attempt to execute an instruction causes an abort, on taking the Hyp Trap exception, the [HSR](#) indicates whether a Data Abort exception or a Prefetch Abort exception caused the Hyp Trap exception entry, and presents a valid syndrome in the [HSR](#).

When [SCR.EA](#) is set to 1, external aborts and SError interrupts are routed to Secure Monitor mode, and this takes priority over the [HCR.TGE](#) routing. For more information, see [Asynchronous exception routing controls on page G1-3841](#). The [SCR.EA](#) control described in that section applies to both synchronous external aborts and asynchronous SError interrupts.

An SError interrupt that is routed to Hyp mode because the value of [HCR.TGE](#) is 1 is reported as a Data Abort exception routed to Hyp mode.

The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information about the exception reporting, see [Use of the HSR on page G4-4137](#).

Reporting of exceptions routed to EL2 using AArch32 because the value of HCR.TGE is 1

[PL1 configurable controls on page G1-3886](#) describes controls that, when the value of [HCR.TGE](#) is 0, can generate exceptions that are taken from Non-secure EL0 to EL1. When EL2 is using AArch32 and the value of [HCR.TGE](#) is 1, the exceptions generated by these controls are routed to Hyp mode. [Table G1-14](#) shows how the exception is then reported in the [HSR](#).

Table G1-14 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables

| Control provided by PL1 | Control type ^a | Syndrome reporting in HSR |
|-------------------------------------|---------------------------|--|
| SCTLR .{nTWE, nTWI} | T | Trapped WFI or WFE instruction, using EC value 0x01 |
| SCTLR .{SED, ITD} | D | Exception for an unknown reason, using EC value 0x00 |
| SCTLR .CP15BEN | E | Exception for an unknown reason, using EC value 0x00 |
| CPACR .TRCDIS | T | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC (coproc==0b1110) access, using EC value 0x05. • MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1110) access, using EC value 0x0C. |
| CPACR .{cp11, cp10} | E | Exception for an unknown reason, using EC value 0x00 |
| FPEXC .EN | E | Exception for an unknown reason, using EC value 0x00 |
| CPACR .ASEDIS | D | Exception for an unknown reason, using EC value 0x00 |

Table G1-14 Syndrome reporting in HSR from HCR.TGE routing of traps, disables, and enables (continued)

| Control provided by PL1 | Control type ^a | Syndrome reporting in HSR |
|--|---------------------------|--|
| DBGDSCRExt.UDCCdis | T | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC (coproc==0b1110) access, using EC value 0x05. LDC or STC instructions, trapped LDC or STC access, using EC value 0x06. MRRC instructions, trapped MCRR or MRRC (coproc==0b1110) access, using EC value 0x0C: |
| CNTKCTL.{PLOPTEN, PLOVTEN, PLOPCTEN, PLOVCTEN} | T | For accesses using: <ul style="list-style-type: none"> MRC or MCR instructions, trapped MCR or MRC (coproc==0b1111) access, using EC value 0x03. MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1111) access, using EC value 0x04. |
| PMUSERENR.{ER, CR, SW, EN} | T | For accesses using: <ul style="list-style-type: none"> MRC or MCR instructions, trapped MCR or MRC (coproc==0b1111) access, using EC value 0x03. MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1111) access, using EC value 0x04. |

a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with [Instruction enables and instruction disables on page G1-3885](#).

Exception reporting when HCR_EL2.TGE routes an exception to EL2 using AArch64

This section give more information about the behavior of synchronous exceptions that are routed from Non-secure EL0 using AArch32 to EL2 using AArch64 because the value of [HCR_EL2.TGE](#) is 1. That is, it describes the behavior of exceptions that are routed from Non-secure User mode to EL2 using AArch64. See:

- [Synchronous aborts from Non-secure User mode, when the value of HCR_EL2.TGE is 1.](#)
- [Reporting of exceptions routed to EL2 using AArch64 because the value of HCR_EL2.TGE is 1 on page G1-3832.](#)

Synchronous aborts from Non-secure User mode, when the value of HCR_EL2.TGE is 1

When executing in Non-secure User mode, the following sections describe synchronous exceptions that can occur:

- [Undefined Instruction exception on page G1-3849.](#)
- [Supervisor Call \(SVC\) exception on page G1-3853.](#)
- [Prefetch Abort exception on page G1-3856.](#)
- [Data Abort exception on page G1-3859.](#)

When EL2 is using AArch64 and the value of [HCR_EL2.TGE](#) is 1, these exceptions are routed to EL2, and reported in the [ESR_EL2](#). [Table G1-15](#) shows how they are reported.

Table G1-15 Syndrome reporting in ESR_EL2 of HCR_EL2 routing of exceptions

| AArch32 exception | Syndrome reporting in ESR_EL2 |
|-----------------------|---|
| Undefined Instruction | Exception for an unknown reason, using EC value 0x00 |
| Supervisor Call | Exception from SVC executed in AArch32 state, using EC value 0x11 |
| Prefetch Abort | Exception from an Instruction abort at a lower Exception level, using EC value 0x20 |
| Data Abort | Exception from a Data abort at a lower Exception level, using EC value 0x24 |

Reporting of exceptions routed to EL2 using AArch64 because the value of `HCR_EL2.TGE` is 1

Table G1-16 shows syndrome reporting for exceptions that are routed from Non-secure User mode to EL2 using AArch64 by `HCR_EL2.TGE`.

For:

- Instruction enable and disable controls provided by PL1, instructions are UNDEFINED when disabled. The Undefined Instruction exceptions that are routed to EL2 using AArch64 are reported with `ESR_EL2.EC` value `0x00`, indicating an unknown reason.
- Trap controls provided by PL1, trapped instructions generate Trap exceptions. These are reported in the `ESR_EL2` with an appropriate EC value.

Table G1-16 Syndrome reporting in `ESR_EL2` of `HCR_EL2` routing of traps. enables and disables

| Control provided by PL1 | Control type ^a | Syndrome reporting in <code>ESR_EL2</code> |
|--|---------------------------|---|
| <code>SCTLR</code> .{nTWE, nTWI} | T | Trapped WFI or WFE instruction, using EC value <code>0x01</code> |
| <code>SCTLR</code> .{SED, ITD} | D | Exception for an unknown reason, using EC value <code>0x00</code> |
| <code>SCTLR</code> .CP15BEN | E | Exception for an unknown reason, using EC value <code>0x00</code> |
| <code>CPACR</code> .TRCDIS | T | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC (coproc==0b1110) access, using EC value <code>0x05</code>. • MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1110) access, using EC value <code>0x0C</code>. |
| <code>CPACR</code> .{cp11, cp10} | E | Exception for an unknown reason, using EC value <code>0x00</code> |
| <code>FPEXC</code> .EN | E | Exception for an unknown reason, using EC value <code>0x00</code> |
| <code>CPACR</code> .ASEDIS | D | Exception for an unknown reason, using EC value <code>0x00</code> |
| <code>DBGDSCRExt</code> .UDCCdis | T | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC (coproc==0b1110) access, using EC value <code>0x05</code>. • LDC or STC instructions, trapped LDC or STC access, using EC value <code>0x06</code>. • MRRC instructions, trapped MCRR or MRRC (coproc==0b1110) access, using EC value <code>0x0C</code>. |
| <code>CNTKCTL</code> .{PLOPTEN, PLOVTEN, PLOPCTEN, PLOVCTEN} | T | For accesses using: <ul style="list-style-type: none"> • MRC or MCR instructions, trapped MCR or MRC (coproc==0b1111) access, using EC value <code>0x03</code>. • MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1111) access, using EC value <code>0x04</code>. |
| <code>PMUSERENR</code> .{ER, CR, SW, EN} | T | For accesses using: <ul style="list-style-type: none"> • MRC or MCR instructions, trapped MCR or MRC (coproc==0b1111) access, using EC value <code>0x03</code>. • MCRR or MRRC instructions, trapped MCRR or MRRC (coproc==0b1111) access, using EC value <code>0x04</code>. |

a. T indicates a trap control, E indicates an instruction enable, and D indicates an instruction disable. For the definition of these terms, see the list that begins with *Instruction enables and instruction disables* on page G1-3885.

For all exceptions that [Table G1-16 on page G1-3832](#) applies to except those generated by [CPACR](#).{cp11, cp10}, [ESR_EL2](#) reporting is the same as it would have been in [ESR_EL1](#) under the following conditions:

- EL1 using AArch64.
- [HCR_EL2](#).TGE set to 0.

For exceptions generated by [CPACR](#).{cp11, cp10}, [ESR_EL2](#) reporting is as follows:

- The [ESR_EL2](#).EC value is reported as 0x00. This differs from the EC value reported in [ESR_EL1](#) when an exception is generated by [CPACR_EL1](#).FPEN and is taken to EL1 using AArch64.

G1.12.7 Routing debug exceptions to EL2

When the value of [HDCR](#).TDE is 1, if the PE is executing in a Non-secure mode other than Hyp mode, any Debug exception is routed to Hyp mode. This means it generates a Hyp Trap exception. This applies to:

- Debug exceptions associated with an instruction fetch, that would otherwise generate a Prefetch Abort exception. These are the Breakpoint, Breakpoint Instruction, and Vector Catch exception, see [Chapter G2 AArch32 Self-hosted Debug](#).
- Watchpoint exceptions associated with data accesses, that would otherwise generate a Data Abort exception. See [Watchpoint exceptions on page G2-3961](#).

When the value of [HDCR](#).TDE is 1, each of the [HDCR](#).{TDRA, TDOSA, TDA} bits is treated as 1 for all purposes other than reading the [HDCR](#) register.

————— **Note** —————

- A Breakpoint or Watchpoint debug event that generates entry to Debug state cannot be trapped to Hyp mode. See [Breakpoint and Watchpoint debug events on page H2-4846](#).
- When [HDCR](#).TDE is set to 1, the Hyp Trap exception is generated instead of the Prefetch Abort exception or Data Abort exception that is otherwise generated by the Debug exception.
- Debug exceptions, other than Breakpoint Instruction exceptions, are never generated in Hyp mode.

When a Hyp Trap exception is generated because [HDCR](#).TDE is set to 1, The [HSR](#) reports the exception either:

- As a Prefetch Abort exception routed to Hyp mode, using the EC value 0x20.
- As a Data Abort exception routed to Hyp mode, using the EC value 0x24.

For more information see [Use of the HSR on page G4-4137](#).

G1.13 Exception return to an Exception level using AArch32

In the ARM architecture, *exception return* to an Exception level that is using AArch32 requires the simultaneous restoration of the PC and **PSTATE** to values that are consistent with the desired state of execution on returning from the exception. Typically, exception return involves returning to one of:

- The instruction after the instruction boundary at which an asynchronous exception was taken.
- The instruction following an SVC, SMC, or HMC instruction, for an exception generated by one of those instructions.
- The instruction that caused the exception, after the reason for the exception has been removed.
- The subsequent instruction, if the instruction that caused the exception has been emulated in the exception handler.

The ARM architecture defines a *preferred return address* for each exception other than Reset, see [Link values saved on exception entry on page G1-3821](#). The values of the **SPSR.IT[7:0]** bits generated on exception entry are always correct for this preferred return address, but might require adjustment by the exception handler if returning elsewhere.

In some cases, to calculate the appropriate preferred return address for a return to an Exception level that is using AArch32, a subtraction must be performed on the link value saved on taking the exception. The description of each exception includes any value that must be subtracted from the link value, and other information about the required exception return.

On an exception return, the **PSTATE** takes either:

- The value loaded by the RFE instruction.
- If the exception return is not performed by executing an RFE instruction, the value of the current **SPSR** at the time of the exception return.

[Illegal return events from AArch32 state on page G1-3835](#) describes the behavior if the restored PE state would not be valid for the Exception level, PE mode, and Security state targeted by the exception return.

G1.13.1 Exception return instructions

The instructions that an exception handler can use to return from an exception depend on whether the exception was taken to an EL1 mode, or in an EL2 mode, see:

- [Return from an exception taken to a PE mode other than Hyp mode.](#)
- [Return from an exception taken to Hyp mode on page G1-3835.](#)

Return from an exception taken to a PE mode other than Hyp mode

For an exception taken to a PE mode other than Hyp mode, the ARM AArch32 architecture provides the following *exception return instructions*:

- From privileged modes other than System mode, the ERET instruction. After the exception return, execution resumes from the address held in the LR (R14) for the mode in which ERET is executed. See [ERET on page F5-2673](#).
- Data-processing instructions with the S bit set and the PC as a destination, see [MOV, MOVS \(register\) on page F5-2815](#) and [SUB, SUBS \(immediate\) on page F5-3114](#).

———— **Note** —————

The A32 instruction set includes other instructions that can be used for an exception return, but ARM deprecates any use of those instructions.

—————

Typically:

- A return where no subtraction is required uses SUBS with an operand of 0, or the equivalent MOVS instruction.
- A return requiring subtraction uses SUBS with a nonzero operand.
- The RFE instruction, see [RFE, RFEDA, RFEDB, RFEIA, RFEIB](#) on page F5-2918. If a subtraction is required, typically it is performed before saving the LR value to memory. After the exception return, execution resumes from the address held in the memory location indicated by the base register specified by the RFE instruction.
- In A32 state, a form of the LDM instruction in which the PC is one of the registers loaded, see [LDM \(exception return\)](#) on page F5-2703. If a subtraction is required, typically it is performed before saving the LR value to memory.

Return from an exception taken to Hyp mode

For an exception taken to Hyp mode, the ARM architecture provides the ERET instruction, see [ERET](#) on page F5-2673. An exception handler executing in Hyp mode must return using the ERET instruction.

Both Hyp mode and the ERET instruction are implemented only as part of EL2.

G1.13.2 Alignment of exception returns

The T bit of the value transferred to the [PSTATE](#) by an exception return controls the target instruction set of that return. The behavior of the hardware for exception returns for different values of the T bit is as follows:

- T == 0** The target instruction set state is A32 state. Bits[1:0] of the address transferred to the PC are ignored by the hardware.
- T == 1** The target instruction set state is T32 state:
- Bit[0] of the address transferred to the PC is ignored by the hardware.
 - Bit[1] of the address transferred to the PC is part of the instruction address.

———— Note —————

In previous versions of the ARM architecture, the [PSTATE](#).{J, T} bits determined the Instruction set state. In ARMv8, [PSTATE](#).J is RES0.

ARM deprecates any dependence on the requirements that the hardware ignores bits of the address. ARM recommends that the address transferred to the PC for an exception return is correctly aligned for the target instruction set.

After an exception entry other than Reset, the LR value has the correct alignment for the instruction set indicated by the [SPSR](#).T bit. This means that if exception return instructions are used with the LR and [SPSR](#) values produced by such an exception entry, the only precaution software needs to take to ensure correct alignment is that any subtraction is of a multiple of four if returning to A32 state, or a multiple of two if returning to T32 state.

G1.13.3 Illegal return events from AArch32 state

Throughout this section:

- Return** In AArch32 state, refers to any of:
- Execution of any exception return instruction.
 - Execution of a DRPS instruction in Debug state.
 - Exit from Debug state.

If an exception or debug return from an Exception level using AArch32 triggers an illegal exception return, then bit[1] of the PC is either:

- Zero.
- The value of bit[1] of the return address for the exception or debug return.

The choice between these two alternatives is made by the implementation, and might differ from instance to instance of an illegal exception return.

———— **Note** ————

This means software must support both alternatives.

Saved process state value

In AArch32 state, refers to any of:

- The value held in the [SPSR](#) for any exception return other than an exception return made by executing an RFE instruction.
- The value read from memory that is to be restored to [PSTATE](#) by the execution of an RFE instruction.
- The value held in the [SPSR](#) for the execution of a DRPS instruction in Debug state.
- The value held in the [DSPSR](#) for a Debug state exit.

Link address In AArch32 state, refers to any of:

- The address held in the link register for any exception return other than an exception return made by executing an ERET, LDM, or RFE instruction.
- The address held in [ELR_hyp](#) for any exception return made by executing an ERET instruction.
- The address read from memory that is to be restored to the PC by the execution of an LDM or RFE instruction.
- The address held in the [DLR](#) for Debug state exit.

Configured from reset

Indicates the state determined on powerup or reset by a configuration input signal, or by another IMPLEMENTATION DEFINED mechanism.

The ARMv8 architecture has a generic mechanism for handling exception or debug returns to a mode or state that is illegal. In AArch32 state, this can occur as a result of any of the following situations:

- A return where the Exception level being returned to is higher than the current Exception level.
- A return where the mode being returned to is not implemented. For example:
 - A return to Hyp mode when EL2 is not implemented.
 - A return to Monitor mode, when EL3 is either not implemented or using AArch64 state.
- A return to EL2 when:
 - EL3 is implemented and using AArch64, and the value of the [SCR_EL3.NS](#) bit is 0.
 - EL3 is implemented and using AArch32, and the value of the [SCR.NS](#) bit is 0.
- A return to Non-secure EL1 when:
 - EL2 is implemented and using AArch64, and the value of the [HCR_EL2.TGE](#) bit is 1.
 - EL2 is implemented and using AArch32, and the value of the [HCR.TGE](#) bit is 1.
- A return where the value of the saved process state M[4:0] field is not a valid AArch32 PE mode for the implementation. [Table G1-5 on page G1-3796](#) shows the valid M[4:0] values for AArch32 PE modes.

In these cases:

- [PSTATE.IL](#) is set to 1, to indicate an illegal return.
- [PSTATE.M](#) is unchanged. This means the PE mode does not change.
- The SS bit is handled in the same way as any other exception or debug return, see [Software Step exceptions on page D2-1673](#).

- The following **PSTATE** bits are restored from the saved process state value:
 - The N, Z, C, V Condition flags.
 - The Q Overflow or saturation flag.
 - The GE Greater than or Equal flags.
 - The E Endianness mapping bit.
 - The A, I, F exception mask bits.
- The **PSTATE**.{IT, T} bits are each either:
 - Set to 0.
 - Copied from the saved process state in the **SPSR** for the PE mode in which the exception is handled.The choice between these two options is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.
- The PC is restored from the link address, unless the illegal return is the execution of a DRPS instruction in Debug state.

When the value of the **PSTATE**.IL bit is 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception*.

All aspects of the illegal return, other than the effects described in this section, are the same as for a legal return.

G1.13.4 Legal returns that set **PSTATE**.IL to 1

In this section, return, saved process state value, and link address have the meaning that is defined in *Illegal return events from AArch32 state on page G1-3835*.

If the IL bit in the saved process state value is 1, then it is copied to **PSTATE** meaning that **PSTATE**.IL is set to 1. In this case, the **PSTATE**.{IT, T} bits are each either:

- Set to 0.
- Copied from the **SPSR**, or loaded from memory if the exception return was performed by executing an RFE instruction.

The choice between these two options is determined by an implementation, and might vary dynamically within the implementation. This means software must regard each value as being an UNKNOWN choice between the two permitted values.

Because the return sets the **PSTATE**.IL bit to 1, any attempt to execute any instruction results in an Illegal Execution state exception. See *The Illegal Execution state exception*.

G1.13.5 The Illegal Execution state exception

When the value of the **PSTATE**.IL bit is 1, any attempt to execute an instruction generates an Illegal Execution state exception. In AArch32 state, the **PSTATE**.IL bit can be set to 1 by one of the following:

- An illegal return, as described in *Illegal return events from AArch32 state on page G1-3835*.
- An illegal change to **PSTATE**.M, as described in *Illegal changes to PSTATE.M on page G1-3809*.
- A legal return that sets **PSTATE**.IL to 1, as described in *Legal returns that set PSTATE.IL to 1*.

An Illegal Execution state exception is taken in the same way as an Undefined Instruction exception in the current Exception level. If the current Exception level is EL2 using AArch32 state, the **HSR** provides additional syndrome information for the exception, see *Use of the HSR on page G4-4137*.

An Illegal Execution state exception has priority over any other Undefined Instruction exception that might arise from instruction execution.

Note

This section only describes the handling of an Illegal Execution state exception that is taken to an Exception level that is using AArch32 state. [The Illegal Execution state exception on page D1-1539](#) describes the cases where an Illegal Execution state exception is taken to an Exception level that is using AArch64 state.

On taking any exception to an Exception level that is using AArch32 state:

1. The value of the `PSTATE.IL` bit is 1 and this is copied to the `SPSR.IL` bit for the PE mode to which the exception is taken.
2. The `PSTATE.IL` bit is cleared to 0.

Note

This means that it is not possible for software to observe the value of `PSTATE.IL`.

Pseudocode description of exception return

The `AArch32.ExceptionReturn()` function transfers the return address to the PC and restores `PSTATE` to its saved value.

This function uses the function `SetPSTATEFromPSR()`.

The `IllegalExceptionReturn()` function checks for an Illegal Execution state exception.

[Chapter J1 ARMv8 Pseudocode](#) includes the definitions of these functions.

G1.14 Asynchronous exception behavior for exceptions taken from AArch32 state

In an implementation that does not include EL2 or EL3, the asynchronous exceptions behave as follows when EL1 and EL0 are both using AArch32:

- An SError interrupt is taken to Abort mode.
- An IRQ exception is taken to IRQ mode.
- An FIQ exception is taken to FIQ mode.

These are the *default PE modes* for taking these exceptions.

———— Note ————

The SError interrupt replaces the ARMv7 asynchronous abort. The new name better describes the nature of the exception.

However, the `PSTATE`.{A, I, F} bits *mask* the asynchronous exceptions, meaning that when the value of one of these `PSTATE` bits is 1, the corresponding exception is not taken.

If a masked asynchronous exception remains signaled, then the exception remains pending unless the value of the `PSTATE` bit is changed to 0.

EL2 and EL3 provide controls that affect:

- The routing of these exceptions, see [Asynchronous exception routing controls on page G1-3841](#).
- Masking of these exceptions in Non-secure state, see [Asynchronous exception masking controls on page G1-3842](#).

Similar register control bits are provided regardless of whether EL2 and EL3 are using AArch32 or AArch64:

- The EL2 controls are provided by the `HCR` when EL2 is using AArch32, and by the `HCR_EL2` when EL2 is using AArch64.
- The EL3 controls are provided by the `SCR` when EL3 is using AArch32, and by the `SCR_EL3` when EL3 is using AArch64.

Therefore, most references to the `HCR` or `SCR` in this section are to entries in [Table K12-1 on page K12-5660](#), that disambiguates between AArch32 registers and AArch64 registers. However, the Execution states used by EL2 and EL3 do affect some aspects of the routing and masking of the asynchronous exceptions, see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3844](#).

G1.14.1 Virtual exceptions when an implementation includes EL2

When implemented, EL2 provides the following virtual exceptions, that correspond to the physical asynchronous exceptions:

- Virtual SError, that corresponds to a physical external SError interrupt.
- Virtual IRQ, that corresponds to a physical IRQ.
- Virtual FIQ, that corresponds to a physical FIQ.

When the value of `HCR.TGE` is 0 and the value of an `HCR`.{AMO, IMO, FMO} routing control bit is 1, the corresponding virtual interrupt is enabled and a virtual exception is generated either:

- By setting the corresponding virtual interrupt pending bit, `HCR`.{VA, VI, VF}, to 1.
- For a Virtual IRQ or Virtual FIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller. See, for example, the *ARM Generic Interrupt Controller Architecture Specification*.

When the value of `HCR_EL2.TGE` is 1 all virtual interrupts are disabled.

When a virtual interrupt is disabled:

- It cannot be taken.
- It cannot be seen in the `ISR`.

In AArch32 state, a virtual exception is taken only from a Non-secure EL1 or EL0 mode. In any other mode, if the exception is generated it is not taken.

A virtual exception is taken in Non-secure state to the default mode for the corresponding physical exception. This means:

- A Virtual SError is taken to Non-secure Abort mode.
- A Virtual IRQ is taken to Non-secure IRQ mode.
- A Virtual FIQ is taken to Non-secure FIQ mode.

Table G1-17 summarizes the HCR bits that route asynchronous exceptions to EL2, and the bits that generate the virtual exceptions.

Table G1-17 HCR bits controlling asynchronous exceptions

| Exception | Routing the physical exception to EL2 | Generating the virtual exception |
|-----------|---------------------------------------|----------------------------------|
| SError | HCR.AMO | HCR.VA |
| IRQ | HCR.IMO | HCR.VI |
| FIQ | HCR.FMO | HCR.VF |

The HCR.{VA, VI, VF} bits generate a virtual exception only if set to 1 when the value of the corresponding HCR.{AMO, IMO, FMO} is 1.

Similarly, if the implementation also includes EL3, the HCR.{AMO, IMO, FMO} bits route the corresponding physical exception to Hyp mode only if the physical exception is not routed to Monitor mode by the SCR.{EA, IRQ, FIQ} bit. For more information, see *Asynchronous exception routing controls* on page G1-3841.

When the value of an HCR.{AMO, IMO, FMO} control bit is 1, the corresponding mask bit in PSTATE:

- Does not mask the physical exception.
- Masks the virtual exception when the PE is executing in a Non-secure EL1 or EL0 mode.

Taking a Virtual Abort exception clears HCR.VA to zero. Taking a Virtual IRQ exception or a Virtual FIQ exception does not affect the value of HCR.VI or HCR.VF.

———— **Note** —————

This means that the exception handler for a Virtual IRQ exception or a Virtual FIQ exception must cause software that is executing at EL2 or EL3 to update the HCR to clear the appropriate virtual exception bit to 0.

See *WFE wake-up events* on page G1-3874 and *Wait For Interrupt* on page G1-3875 for information about how virtual exceptions affect wake up from power-saving states.

———— **Note** —————

A hypervisor can use virtual exceptions to signal exceptions to the current Guest OS. The Guest OS takes a virtual exception exactly as it would take the corresponding physical exception, and is unaware of any distinction between virtual exception and the corresponding physical exception.

Effects of the HCR.{AMO, IMO, FMO} bits

As described in this section, the HCR.{AMO, IMO, FMO} bits are part of the mechanism for enabling the virtual exceptions. In addition, for exceptions generated in Non-secure state:

- As mentioned in this section, affect the routing of the exceptions. See *Asynchronous exception routing controls* on page G1-3841.
- Affect the masking of the exceptions. See *Asynchronous exception masking controls* on page G1-3842.

G1.14.2 Asynchronous exception routing controls

Note

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see [Asynchronous exception routing and masking with higher Exception levels using AArch64 on page G1-3844](#).

In an implementation that includes EL3 the following bits in the **SCR** control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

SCR.EA When the value of this bit is 1, any synchronous external abort or SError interrupt is taken to EL3.

Note

- Although this section describes the asynchronous exception routing controls, **SCR.EA** controls the routing of both synchronous external aborts and asynchronous SError interrupts.
- The other classes of abort cannot be routed to EL3. For more information about the classification of aborts, see [VMSAv8-32 memory aborts on page G4-4110](#).

SCR.FIQ When the value of this bit is 1, any FIQ exception is taken to EL3.

SCR.IRQ When the value of this bit is 1, any IRQ exception is taken to EL3.

When EL3 is using AArch32 and the value of one of the **SCR**.{EA, FIQ, IRQ} bits is 1, the exception is taken to Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes EL2, the following bits in the **HCR** route asynchronous exceptions to EL2, for exceptions that are both:

- Taken from a Non-secure EL1 or EL0 mode.
- If the implementation also includes EL3, not configured, by the **SCR**.{EA, FIQ, IRQ} controls, to be taken to EL3.

HCR.AMO When the value of this bit is 1, an SError interrupt exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure Abort mode. If the implementation also includes EL3, this control applies only if the value of **SCR.EA** is 0. When the value of **SCR.EA** is 1, the value of the AMO bit is ignored.

HCR.FMO When the value of this bit is 1, an FIQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure FIQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.FIQ** is 0. When the value of **SCR.FIQ** is 1, the value of the FMO bit is ignored.

HCR.IMO When the value of this bit is 1, an IRQ exception taken from a Non-secure EL1 or EL0 mode is taken to EL2, instead of to Non-secure IRQ mode. If the implementation also includes EL3, this control applies only if the value of **SCR.IRQ** is 0. When the value of **SCR.IRQ** is 1, the value of the IMO bit is ignored.

When EL2 is using AArch32 and the value of one of the **HCR**.{AMO, FMO, IMO} bits is 1, the exception is taken to Hyp mode.

Only software executing in Hyp mode, or Secure software executing at EL3 with **SCR.NS** set to 1, can change the values of these bits. If EL3 is using AArch32, this requires the Secure software to be executing in Monitor mode.

The **HCR**.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in [Asynchronous exception masking controls on page G1-3842](#).

The **SCR**.{EA, FIQ, IRQ} and **HCR**.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

———— **Note** —————

When the PE is in Hyp mode:

- Physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode.
- Virtual exceptions are not signaled to the PE.

See also [Asynchronous exception behavior for exceptions taken from AArch32 state](#) on page G1-3839.

G1.14.3 Asynchronous exception masking controls

———— **Note** —————

This section describes the behavior when all exception levels are using AArch32. For the differences when this is not the case see [Asynchronous exception routing and masking with higher Exception levels using AArch64](#) on page G1-3844.

The `PSTATE`.{A, I, F} bits can mask the taking of the corresponding exceptions from AArch32 state, as follows:

- `PSTATE`.A can mask SError interrupt exceptions.
- `PSTATE`.I can mask IRQ exceptions.
- `PSTATE`.F can mask FIQ exceptions.

In an implementation that does not include either of EL2 and EL3, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes EL2, the `HCR`.{AMO, IMO, FMO} bits modify the masking of exceptions taken from Non-secure state.

Similarly, in an implementation that includes EL3, the `SCR`.{AW, FW} bits modify the masking of exceptions taken from Non-secure state by the `PSTATE`.{A, F} bits.

An implementation that includes only EL1 and EL0 does not provide any masking of the `PSTATE`.{A, I, F} bits. The following subsections describe the masking of these bits in other implementations:

- [Asynchronous exception masking in an implementation that includes EL2 but not EL3](#).
- [Asynchronous exception masking in an implementation that includes EL3 but not EL2](#).
- [Asynchronous exception masking in an implementation that includes both EL2 and EL3](#) on page G1-3843.
- [Summary of the asynchronous exception masking controls](#) on page G1-3843.

Asynchronous exception masking in an implementation that includes EL2 but not EL3

The `HCR`.{AMO, IMO, FMO} bits modify the effect of the `PSTATE`.{A, I, F} bits. When the value of an `HCR`.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding `PSTATE`.{A, I, F} bit is ignored when the exception is taken from a Non-secure mode other than Hyp mode.

Asynchronous exception masking in an implementation that includes EL3 but not EL2

The `SCR`.{AW, FW} bits modify the effect of the `PSTATE`.{A, F} bits. When the value of one of the `SCR`.{AW, FW} bits is 0, the corresponding `PSTATE` bit is ignored when both of the follow apply:

- The corresponding exception is taken from Non-secure state.
- The value of the corresponding `SCR`.{EA, FIQ} bit is 1, routing the exception to EL3. This means the exception is routed to Monitor mode if EL3 is using AArch32.

———— **Note** —————

Whenever the value of `PSTATE`.I is 1, IRQ exceptions are masked and cannot be taken.

Asynchronous exception masking in an implementation that includes both EL2 and EL3

When the value of an **HCR**.{AMO, IMO, FMO} mask override bit is 1, the value of the corresponding **PSTATE**.{A, I, F} bit is ignored when both of the following apply:

- The exception is taken from Non-secure state.
- Either:
 - The corresponding **SCR**.{EA, IRQ, FIQ} bit routes the exception to Monitor mode.
 - The exception is taken from a Non-secure mode other than Hyp mode.

In addition, when the value of an **SCR**.{AW, FW} bit is 0, the value of the corresponding **PSTATE**.{A, F} bit is ignored when all of the following apply:

- The exception is taken from Non-secure state.
- The corresponding **SCR**.{EA, FIQ} bit routes the exception to Monitor mode.
- The corresponding **HCR**.{AMO, FMO} mask override bit is set to 0.

Summary of the asynchronous exception masking controls

The tables in this section show the masking controls for each of the **PSTATE**.{A, I, F} bits. For an implementation that does not include all of the exception levels:

If the implementation includes only EL1 and EL0

The **PSTATE** bits cannot be masked. The behavior is as shown in the *Secure* row of the tables.

If the implementation includes EL2 but not EL3

The behavior is as shown in the *Non-secure* table rows when the control bits in the **SCR** are both 0.

If the implementation includes EL3 but not EL2

The behavior is as shown in the table rows where the control bit in the **HCR** is 0.

Table G1-18 shows the controls of the masking of SError interrupt exceptions by **PSTATE**.A.

Table G1-18 Control of masking by **PSTATE.A**

| Security state | HCR .AMO | SCR .EA | SCR .AW | Mode | PSTATE .A | |
|----------------|-----------------|----------------|----------------|------|---------------------------------------|---------------------------------------|
| Secure | x | x | x | x | Masks SError interrupt, when set to 1 | |
| Non-secure | 0 | 0 | x | x | Masks SError interrupt, when set to 1 | |
| | | | 1 | 0 | x | Ignored |
| | | 1 | 1 | x | Masks SError interrupt, when set to 1 | |
| | 1 | x | x | x | Not Hyp | Ignored |
| | | | 0 | x | Hyp | Masks SError interrupt, when set to 1 |
| | | 1 | x | x | x | Ignored |

Table G1-19 shows the controls of the masking of FIQ exceptions by **PSTATE.F**:

Table G1-19 Control of masking by **PSTATE.I**

| Security state | HCR.IMO | SCR.IRQ | Mode | PSTATE.I |
|----------------|---------|---------|---------|---------------------------|
| Secure | x | x | x | Masks IRQs, when set to 1 |
| Non-secure | 0 | x | x | Masks IRQs, when set to 1 |
| | | 1 | Not Hyp | Ignored |
| | 1 | 0 | Hyp | Masks IRQs, when set to 1 |
| | | 1 | x | Ignored |

Table G1-20 shows the controls of the masking of FIQ exceptions by **PSTATE.F**:

Table G1-20 Control of masking by **PSTATE.F**

| Security state | HCR.FMO | SCR.FIQ | SCR.FW | Mode | PSTATE.F | |
|----------------|---------|---------|--------|------|---------------------------|---------------------------|
| Secure | x | x | x | x | Masks FIQs, when set to 1 | |
| Non-secure | 0 | 0 | x | x | Masks FIQs, when set to 1 | |
| | | | 1 | 0 | x | Ignored |
| | | 1 | x | x | Not Hyp | Ignored |
| | 1 | 0 | x | x | Hyp | Masks FIQs, when set to 1 |
| | | | 1 | x | x | Ignored |

G1.14.4 Asynchronous exception routing and masking with higher Exception levels using AArch64

Asynchronous exception routing controls on page G1-3841 and *Asynchronous exception masking controls* on page G1-3842 give full descriptions of the routing and masking of the asynchronous exceptions when all Exception levels are using AArch32. However, when EL0 and EL1 are using AArch32:

- As already described, the **SCR** and **HCR** controls might be from Exception levels that are using AArch64.
- If EL3 is using AArch64, or EL2 is using AArch64, there are some changes to the asynchronous exception behaviors.

Therefore, the following sections summarize the asynchronous exception behaviors, taking account of the Execution state being used at EL2 and EL3:

- *Summary of physical interrupt routing.*
- *Summary of physical interrupt masking on page G1-3846.*

Summary of physical interrupt routing

The following tables show the routing of physical interrupts. [Table G1-21 on page G1-3845](#) shows the routing of physical FIQ interrupts, [Table G1-22 on page G1-3845](#) shows the routing of physical IRQ interrupts, and [Table G1-23 on page G1-3846](#) shows the routing of physical SError interrupts.

In these tables, for exceptions that must be taken to an Exception level that is using AArch32, the table shows the target Exception level and PE mode. In these entries, *Mon* indicates Monitor mode, and *Abt* indicates Abort mode.

Table G1-21 Routing of physical FIQ exceptions

| EL3 Execution state | Control bits | | | Target when take from: | | | | | | |
|---------------------|--------------|-----|-----------------|------------------------|------------------|------------------|------------------|------------------|------------------|----------------|
| | SCR | HCR | | Non-secure | | | Secure | | | |
| | | FIQ | RW ^a | FMO ^b | EL0 | EL1 | EL2 | EL0 | EL1 ^c | EL3 |
| AArch32 | 0 | x | 0 | EL1 FIQ | EL1 FIQ | EL2 Hyp | EL3 FIQ | - | EL3 FIQ | |
| | | | 1 | EL2 Hyp | EL2 Hyp | EL2 Hyp | EL3 FIQ | - | EL3 FIQ | |
| | 1 | x | x | EL3 Mon | EL3 Mon | EL3 Mon | EL3 Mon | - | EL3 Mon | |
| AArch64 | 0 | 0 | 0 | EL1 FIQ | EL1 FIQ | EL2 Hyp | EL1 FIQ | EL1 FIQ | P ^d | |
| | | | x | 1 | EL2 ^e | EL2 ^e | EL2 ^e | EL1 ^f | EL1 ^f | P ^d |
| | | | 1 | 0 | EL1 | EL1 | P ^d | EL1 | EL1 | P ^d |
| | 1 | x | x | EL3 | EL3 | EL3 | EL3 | EL3 | EL3 | |

- a. [SCR_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.
- f. If EL1 is using AArch32, taken to Abort mode.

Table G1-22 Routing of physical IRQ exceptions

| EL3 Execution state | Control bits | | | Target when take from: | | | | | | |
|---------------------|--------------|-----|-----------------|------------------------|------------------|------------------|------------------|------------------|------------------|----------------|
| | SCR | HCR | | Non-secure | | | Secure | | | |
| | | IRQ | RW ^a | IMO ^b | EL0 | EL1 | EL2 | EL0 | EL1 ^c | EL3 |
| AArch32 | 0 | x | 0 | EL1 IRQ | EL1 IRQ | EL2 Hyp | EL3 IRQ | - | EL3 IRQ | |
| | | | 1 | EL2 Hyp | EL2 Hyp | EL2 Hyp | EL3 IRQ | - | EL3 IRQ | |
| | 1 | x | x | EL3 Mon | EL3 Mon | EL3 Mon | EL3 Mon | - | EL3 Mon | |
| AArch64 | 0 | 0 | 0 | EL1 IRQ | EL1 IRQ | EL2 Hyp | EL1 IRQ | EL1 IRQ | P ^d | |
| | | | x | 1 | EL2 ^e | EL2 ^e | EL2 ^e | EL1 ^f | EL1 ^f | P ^d |
| | | | 1 | 0 | EL1 | EL1 | P ^d | EL1 | EL1 | P ^d |
| | 1 | x | x | EL3 | EL3 | EL3 | EL3 | EL3 | EL3 | |

- a. [SCR_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.

f. If EL1 is using AArch32, taken to Abort mode.

Table G1-23 Routing of physical SError interrupts

| EL3 Execution state | Control bits | | | Target when take from: | | | | | |
|---------------------|--------------|-----------------|-------------------------|------------------------|------------------|------------------|------------------|------------------|----------------|
| | SCR EA | RW ^a | HCR AMO ^b | Non-secure | | | Secure | | |
| | | | | EL0 | EL1 | EL2 | EL0 | EL1 ^c | EL3 |
| AArch32 | 0 | x | 0 | EL1 Abt | EL1 Abt | EL2 Hyp | EL3 Abt | - | EL3 Abt |
| | | | 1 | EL2 Hyp | EL2 Hyp | EL2 Hyp | EL3 Abt | - | EL3 Abt |
| | 1 | x | x | EL3 Mon | EL3 Mon | EL3 Mon | EL3 Mon | - | EL3 Mon |
| AArch64 | 0 | 0 | 0 | EL1 Abt | EL1 Abt | EL2 Hyp | EL1 Abt | EL1Abt | P ^d |
| | | x | 1 | EL2 ^e | EL2 ^e | EL2 ^e | EL1 ^f | EL1 ^f | P ^d |
| | | 1 | 0 | EL1 | EL1 | P ^d | EL1 | EL1 | P ^d |
| | 1 | x | x | EL3 | EL3 | EL3 | EL3 | EL3 | EL3 |

- a. [SCR_EL3.RW](#). When 1, the next lower Exception level is using AArch64. This control is not present when EL3 is using AArch32.
- b. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- c. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.
- d. Interrupt is not taken, but remains pending.
- e. If EL2 is using AArch32, taken to Hyp mode.
- f. If EL1 is using AArch32, taken to Abort mode.

Summary of physical interrupt masking

The following tables show the masking of physical interrupts. [Table G1-24 on page G1-3847](#) shows the masking of physical FIQ interrupts, [Table G1-25 on page G1-3847](#) shows the masking of physical IRQ interrupts, and [Table G1-26 on page G1-3848](#) shows the masking of physical SError interrupts. In these tables:

- M** Indicates that the exception is masked when the value of the [PSTATE](#) mask bit is 1.
- T** Indicates that the exception is taken, regardless of the value of the [PSTATE](#) mask bit.
- P** Indicates that the exception is not taken but remains pending. The value of the [PSTATE](#) mask bit has no effect on this behavior.

Table G1-24 Masking of physical FIQ exceptions

| EL3 Execution state | Control bits | | | Effect of PSTATE.F ^a mask in Exception level | | | | | | | |
|---------------------------|--------------|----|-----------------|--|------------|------------------|-----|--------|-----|-----|------------------|
| | SCR | FW | RW ^b | HCR | Non-secure | | | Secure | | | |
| | | | | | FIQ | FMO ^c | EL0 | EL1 | EL2 | EL0 | EL1 ^d |
| AArch32 | 0 | x | x | 0 | M | M | M | M | - | M | |
| | | | | 1 | T | T | M | M | - | M | |
| | 1 | 0 | x | 0 | T | T | T | M | - | M | |
| | | | | 1 | M | M | M | M | - | M | |
| | | | | x | T | T | T | M | - | M | |
| AArch64 | 0 | x | 0 | 0 | M | M | M | M | M | P | |
| | | | | 1 | T | T | M | M | M | P | |
| | | | 1 | x | 0 | M | M | P | M | M | P |
| | | | | | 1 | T | T | M | M | M | P |
| | 1 | x | x | x | T | T | T | T | T | M | |

- In AArch32 state this is visible as **CPSR.F**.
- SCR_EL3** only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- When the value of **HCR.TGE** is 1, the effective value of this bit is 1.
- When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-25 Masking of physical IRQ exceptions

| EL3 Execution state | Control bits | | | Effect of PSTATE.I ^a mask in Exception level | | | | | | |
|---------------------------|--------------|-----------------|-----|--|------------------|-----|--------|-----|-----|------------------|
| | SCR | RW ^b | HCR | Non-secure | | | Secure | | | |
| | | | | IRQ | IMO ^c | EL0 | EL1 | EL2 | EL0 | EL1 ^d |
| AArch32 | 0 | x | 0 | M | M | M | M | - | M | |
| | | | 1 | T | T | M | M | - | M | |
| | 1 | x | 0 | M | M | M | M | - | M | |
| | | | 1 | T | T | T | M | - | M | |
| AArch64 | 0 | 0 | 0 | M | M | M | M | M | P | |
| | | | 1 | T | T | M | M | M | P | |
| | | | 1 | 0 | M | M | P | M | M | P |
| | | | | 1 | T | T | M | M | M | P |
| | 1 | x | x | x | T | T | T | T | T | M |

- a. In AArch32 state this is visible as [CPSR.I](#).
- b. [SCR_EL3](#) only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- c. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

Table G1-26 Masking of physical SError interrupts

| EL3 Execution state | Control bits | | | Effect of PSTATE.A ^a mask in Exception level | | | | | | | |
|---------------------|--------------|----|-----------------|---|------------|-----|-----|--------|------------------|-----|---|
| | SCR EA | AW | RW ^b | HCR | Non-secure | | | Secure | | | |
| | | | | AMO ^c | EL0 | EL1 | EL2 | EL0 | EL1 ^d | EL3 | |
| AArch32 | 0 | x | x | 0 | M | M | M | M | - | M | |
| | | | | 1 | T | T | M | M | - | M | |
| | 1 | 0 | x | 0 | T | T | T | M | - | M | |
| | | 1 | x | 0 | M | M | M | M | - | M | |
| AArch64 | 0 | x | 0 | 0 | M | M | M | M | M | P | |
| | | | | 1 | T | T | M | M | M | P | |
| | | | | 1 | 0 | M | M | P | M | M | P |
| | | | | 1 | T | T | M | M | M | P | |
| | 1 | x | x | x | T | T | T | T | T | M | |

- a. In AArch32 state this is visible as [CPSR.A](#).
- b. [SCR_EL3](#) only, this control is not present when EL3 is using AArch32. When the value of RW is 1, the next lower Exception level is using AArch64.
- c. When the value of [HCR.TGE](#) is 1, the effective value of this bit is 1.
- d. When EL3 is using AArch32, the only Secure Exception levels are EL0 and EL3.

G1.15 AArch32 state exception descriptions

Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812 gives general information about exception handling. This section describes each of the exceptions, in the following subsections:

- *Undefined Instruction exception.*
- *Monitor Trap exception on page G1-3851.*
- *Hyp Trap exception on page G1-3852.*
- *Supervisor Call (SVC) exception on page G1-3853.*
- *Secure Monitor Call (SMC) exception on page G1-3854.*
- *Hypervisor Call (HVC) exception on page G1-3855.*
- *Prefetch Abort exception on page G1-3856.*
- *Data Abort exception on page G1-3859.*
- *Virtual SError interrupt exception on page G1-3862.*
- *IRQ exception on page G1-3863.*
- *Virtual IRQ exception on page G1-3864.*
- *FIQ exception on page G1-3865.*
- *Virtual FIQ exception on page G1-3866.*

Additional pseudocode functions for exception handling on page G1-3867 gives additional pseudocode that is used in the pseudocode descriptions of a number of the exceptions.

G1.15.1 Undefined Instruction exception

An Undefined Instruction exception might be caused by:

- A System register access, floating-point, or Advanced SIMD instruction that is not accessible because of the settings in one or more of the CPACR, NSACR, HCPTR, and DBGDSCRExt.
- A System register access, floating-point, or Advanced SIMD instruction that is not implemented.
- A System register access, floating-point, or Advanced SIMD instruction that causes an exception during execution. This includes:
 - Trapped floating-point exceptions that are taken to AArch32, if an implementation supports these traps. See *Floating-point exceptions on page E1-2303*.
 - Execution of certain floating-point instructions when one or both of the FPSCR.{Stride, Len} fields in nonzero, in an implementation in which those fields are RW. The description of FPEXC specifies the instructions to which this applies.
- An instruction that is UNDEFINED.

———— Note —————

The Undefined Instruction exception is taken using offset 0x04 in the Hyp, Secure, or Non-secure vector table. In the Monitor vector table this offset is used for the Monitor Trap exception. See *Monitor Trap exception on page G1-3851* and *The vector tables and exception offsets on page G1-3813*.

By default, an Undefined Instruction exception is taken to Undefined mode, but an Undefined Instruction exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see *The PE mode to which the Undefined Instruction exception is taken on page G1-3850*.

The Undefined Instruction exception can provide:

- Signaling of an illegal instruction execution.
- *Lazy context switching* of System registers.

The preferred return address for an Undefined Instruction exception is the address of the instruction that generated the exception. This return is performed as follows:

- If returning from Secure or Non-secure Undefined mode, the exception return uses the **SPSR** and **LR_und** values generated by the exception entry, as follows:
 - If **SPSR.T** is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
 - If **SPSR.T** is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.
- If returning from Hyp mode, the exception return is performed by an **ERET** instruction, using the **SPSR** and **ELR_hyp** values generated by the exception entry.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3834.

———— **Note** ————

If handling the Undefined Instruction exception requires instruction emulation, followed by return to the next instruction after the instruction that caused the exception, the instruction emulator must use the instruction length to calculate the correct return address, and to calculate the updated values of the IT bits if necessary.

The PE mode to which the Undefined Instruction exception is taken

Figure G1-4 shows how the implementation, state, and configuration options determine the PE mode to which an Undefined Instruction exception is taken.

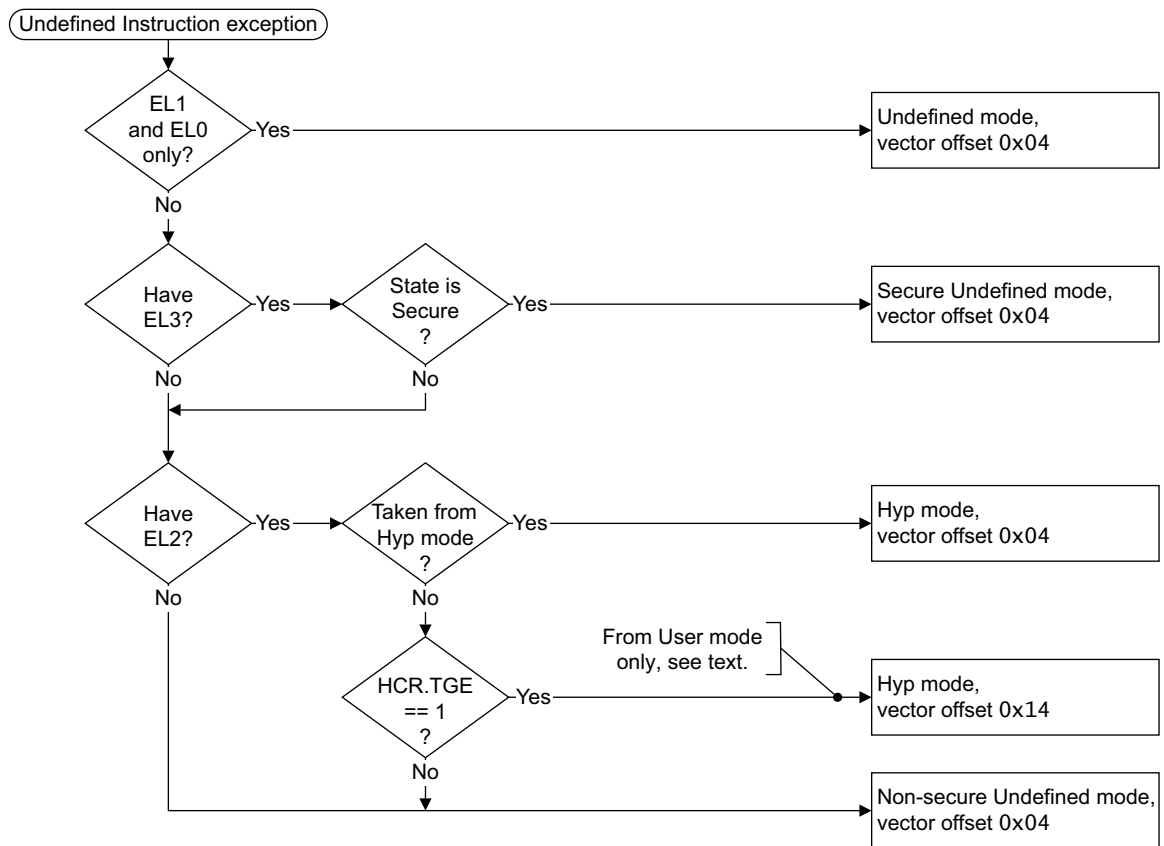

Figure G1-4 The PE mode the Undefined Instruction exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3826.

Pseudocode description of taking the Undefined Instruction exception

The `AArch32.TakeUndefInstrException()` pseudocode procedure describes how the PE takes the exception.

Conditional execution of undefined instructions

The conditional execution rules described in [Conditional execution on page F2-2407](#) apply to all instructions. This includes undefined instructions and other instructions that would cause entry to the Undefined Instruction exception.

If such an instruction fails its condition check, the behavior depends on the potential cause of entry to the Undefined Instruction exception, as follows:

- If the potential cause is the execution of the instruction itself and depends on data values used by the instruction, the instruction executes as a NOP and does not cause an Undefined Instruction exception.
- In the following cases, it is IMPLEMENTATION DEFINED whether the instruction executes as a NOP or causes an Undefined Instruction exception:
 - The potential cause is the execution of an earlier System register access instruction, floating-point instruction, or Advanced SIMD instruction.
 - The potential cause is the execution of the instruction itself without dependence on the data values used by the instruction.

An implementation must handle all such cases in the same way.

———— Note —————

Before ARMv7, all implementations executed any instruction that failed its condition check as a NOP, even if it would otherwise have caused an Undefined Instruction exception. An Undefined Instruction handler written for these implementations might assume without checking that the undefined instruction passed its condition check. Such an Undefined Instruction handler is likely to need rewriting, to check the condition is passed, before it functions correctly on all AArch32 implementations.

Interaction of UNDEFINED instruction behavior with UNPREDICTABLE or CONSTRAINED UNPREDICTABLE instruction behavior

If this manual describes an instruction as both:

- UNPREDICTABLE and UNDEFINED then the instruction is UNPREDICTABLE.
- CONSTRAINED UNPREDICTABLE and UNDEFINED then the instruction is CONSTRAINED UNPREDICTABLE.

———— Note —————

An example of this is where both:

- An instruction, or instruction class, is made UNDEFINED by some general principle, or by a configuration field.
- A particular encoding of that instruction or instruction class is specified as CONSTRAINED UNPREDICTABLE.

G1.15.2 Monitor Trap exception

The Monitor Trap exception is implemented only as part of EL3, and can be generated only if EL3 is using AArch32.

———— Note —————

The Monitor Trap exception is taken using offset `0x04` in the Monitor vector table. In the other vector tables, this offset is used for the Undefined Instruction exception. See [Undefined Instruction exception on page G1-3849](#) and [The vector tables and exception offsets on page G1-3813](#).

A Monitor Trap exception is generated if the PE is running in a mode other than Monitor mode, and commits for execution a WFI or WFE instruction that would otherwise cause suspension of execution when:

- In the case of the WFI instruction, the value of the [SCR.TWI](#) bit is 1.
- In the case of the WFE instruction, the value of the [SCR.TWE](#) bit is 1.

Note

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

The preferred return address for a Monitor Trap exception is the address of the instruction that generated the exception. The exception return uses the [SPSR](#) and [LR_mon](#) values generated by the exception entry, as follows:

- If [SPSR.T](#) is 0, indicating that the exception occurred in A32 state, the return uses an exception return instruction with a subtraction of 4.
- If [SPSR.T](#) is 1, indicating that the exception occurred in T32 state, the return uses an exception return instruction with a subtraction of 2.

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-3834.

The PE mode to which the Monitor Trap exception is taken

When EL3 is using AArch32, a Monitor Trap exception is taken to Monitor mode, using a vector offset of 0x04 from the Monitor exception base address.

Pseudocode description of taking the Monitor Trap exception

The [AArch32.TakeMonitorTrapException\(\)](#) pseudocode procedure describes how the PE takes the exception.

G1.15.3 Hyp Trap exception

The Hyp Trap exception provides the standard mechanism for trapping Guest OS functions to the hypervisor.

The Hyp Trap exception is implemented only as part of EL2 and can be generated only if EL2 is using AArch32.

A Hyp Trap exception is generated if the PE is running in a Non-secure mode other than Hyp mode, and commits for execution an instruction that is trapped to Hyp mode. Instruction traps are enabled by setting bits to 1 in the [HCR](#), [HCPTR](#), [HDCR](#), or [HSTR](#). For more information see [EL2 configurable controls](#) on page G1-3894.

Traps to Hyp mode never apply in Secure state, regardless of the value of the [SCR.NS](#) bit.

The preferred return address for a Hyp Trap exception is the address of the trapped instruction. The exception return is performed by an ERET instruction, using the [SPSR](#) and [ELR_hyp](#) values generated by the exception entry.

Note

The [SPSR](#) and [ELR_hyp](#) values generated on exception entry can be used, without modification, for an exception return to re-execute the trapped instruction. If the exception handler emulates the trapped instruction, and must return to the following instruction, the emulation of the instruction must include modifying [ELR_hyp](#), and possibly updating [SPSR_hyp](#).

When the PE enters the handler for a Hyp Trap exception, the [HSR](#) holds syndrome information for the exception. For more information see [Use of the HSR](#) on page G4-4137.

The PE mode to which the Hyp Trap exception is taken

A Hyp Trap exception is taken to Hyp mode, using a vector offset of 0x14 from the Hyp exception base address.

Pseudocode description of taking the Hyp Trap exception

The `AArch32.TakeHypTrapException()` pseudocode procedure describes how the PE takes the exception.

G1.15.4 Supervisor Call (SVC) exception

The Supervisor Call instruction, SVC, requests a supervisor function, typically to request an operating system function. When EL1 is using AArch32, executing an SVC instruction causes the PE to enter Supervisor mode. For more information, see [SVC on page F5-3129](#).

———— Note ————

In an implementation that includes EL2:

- When an SVC instruction is executed in Hyp mode, the Supervisor Call exception is taken to Hyp mode. For more information see [SVC on page F5-3129](#).
- When the `HCR.TGE` bit is set to 1, the Supervisor Call exception generated by execution of an SVC instruction in Non-secure User mode is routed to Hyp mode. For more information, see [Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-3829](#).

By default, a Supervisor Call exception is taken to Supervisor mode, but a Supervisor Call exception can be taken to EL2, meaning it is taken to Hyp mode if EL2 is using AArch32, see [The PE mode to which the Supervisor Call exception is taken](#).

The preferred return address for a Supervisor Call exception is the address of the next instruction after the SVC instruction. This return is performed as follows:

- If returning from Secure or Non-secure Supervisor mode, the exception return uses the `SPSR` and `LR_svc` values generated by the exception entry, in an exception return instruction without subtraction.
- If returning from Hyp mode, the exception return is performed by an ERET instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

The PE mode to which the Supervisor Call exception is taken

[Figure G1-5 on page G1-3854](#) shows how the implementation, state, and configuration options determine the PE mode to which a Supervisor Call exception is taken.

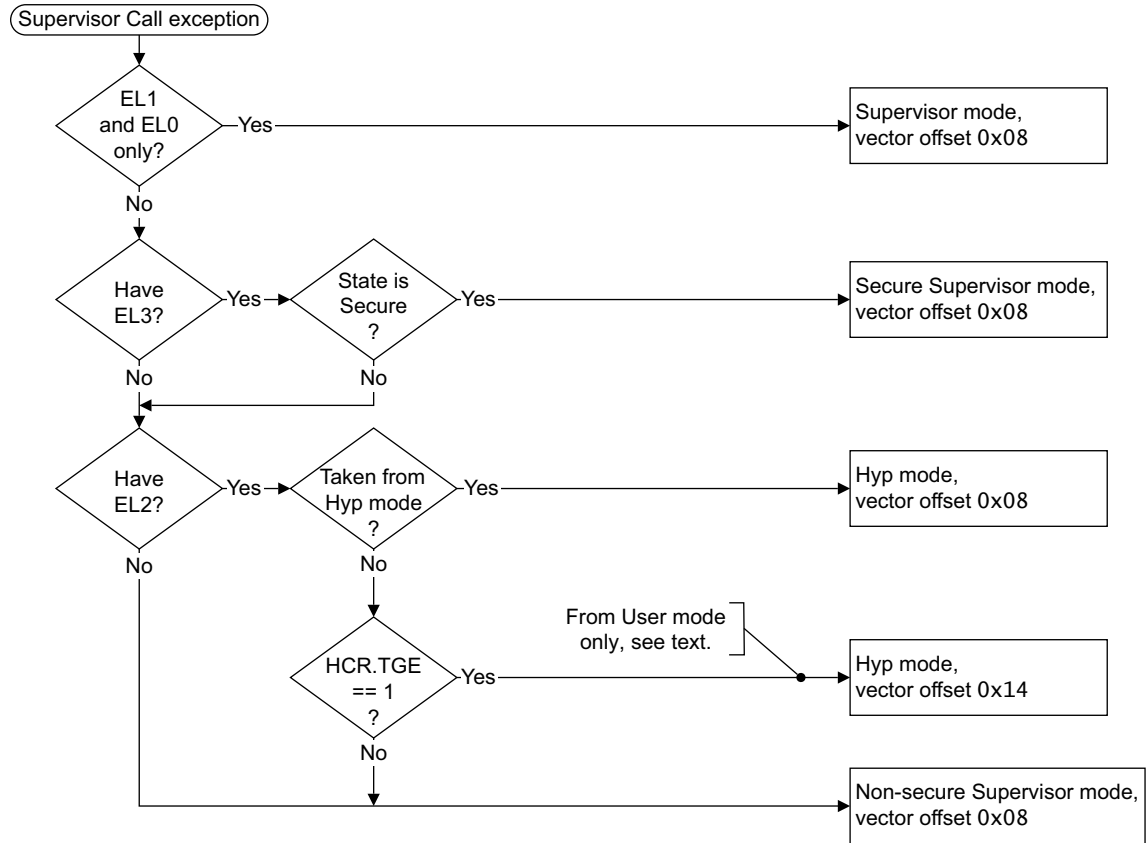

Figure G1-5 The PE mode the Supervisor Call exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3826.

Pseudocode description of taking the Supervisor Call exception

The `AArch32.TakeSVCException()` pseudocode procedure describes how the PE takes the exception.

G1.15.5 Secure Monitor Call (SMC) exception

The Secure Monitor Call exception is implemented only as part of EL3. When EL3 is using AArch32, the exception is taken to Monitor mode.

The Secure Monitor Call instruction, SMC, requests a Secure Monitor function. When EL3 is using AArch32, executing an SMC instruction causes the PE to enter Monitor mode. For more information, see *SMC on page F5-2983*.

———— **Note** ————

In an implementation that includes EL2, execution of an SMC instruction in a Non-secure EL1 mode can be trapped to EL2. When EL2 is using AArch32, this means that when `HCR.TSC 1`, execution of an SMC instruction in a Non-secure EL1 mode generates a Hyp Trap Exception that is taken to Hyp mode. For more information see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3901*.

The preferred return address for a Secure Monitor Call exception is the address of the next instruction after the SMC instruction. This return is performed using the `SPSR` and `LR_mon` values generated by the exception entry, using an exception return instruction without a subtraction.

For more information, see *Exception return to an Exception level using AArch32 on page G1-3834*.

Note

The exception handler can return to the SMC instruction itself by returning using a subtraction of 4, without any adjustment to the `SPSR.IT[7:0]` bits. If it does this, the return occurs, then asynchronous exceptions might occur and be handled, then the SMC instruction is re-executed and another Secure Monitor Call exception occurs.

This relies on:

- The SMC instruction being used correctly, either outside an IT block or as the last instruction in an IT block, so that the `SPSR.IT[7:0]` bits indicate unconditional execution.
 - The Secure Monitor Call handler not changing the result of the original conditional execution test for the SMC instruction.
-

The PE mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of EL3. When EL3 is using AArch32, a Secure Monitor Call exception is taken to Monitor mode, using vector offset `0x08` from the Monitor exception base address.

Note

- An SMC instruction that is trapped to Hyp mode because `HCR.TSC` is set to 1 generates a Hyp Trap exception, see [The PE mode to which the Hyp Trap exception is taken on page G1-3852](#).
 - If EL3 is using AArch64 then [Security behavior in Exception levels using AArch32 when EL3 is using AArch64 on page G1-3824](#) describes the effect of executing an SMC instruction in a mode that is part of an Exception level that is using EL1.
-

Pseudocode description of taking the Secure Monitor Call exception

The `AArch32.TakeSMCException()` pseudocode procedure describes how the PE takes the exception.

G1.15.6 Hypervisor Call (HVC) exception

The Hypervisor Call exception is implemented only as part of EL2.

The Hypervisor Call instruction, HVC, requests a hypervisor function. When EL2 is using AArch32, executing an HVC instruction generates a Hypervisor Call exception that is taken to Hyp mode. For more information, see [HVC on page F5-2677](#).

The preferred return address for a Hypervisor Call exception is the address of the next instruction after the HVC instruction. The exception return is performed by an ERET instruction, using the `SPSR` and `ELR_hyp` values generated by the exception entry.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

When EL2 is using AArch32, executing an HVC instruction transfers the immediate argument of the instruction to the `HSR`. The exception handler retrieves the argument from the `HSR`, and therefore does not have to access the original HVC instruction. For more information see [Use of the HSR on page G4-4137](#).

The PE mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of EL2. When EL2 is using AArch32, a Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as [Figure G1-6 on page G1-3856](#) shows. This offset is from the Hyp exception base address.

Figure G1-6 The PE mode the Hypervisor Call exception is taken to

Pseudocode description of taking the Hypervisor Call exception

The [AArch32.TakeHVCEXception\(\)](#) pseudocode procedure describes how the PE takes the exception.

G1.15.7 Prefetch Abort exception

A Prefetch Abort exception can be generated by:

- A synchronous memory abort on an instruction fetch.

———— **Note** ————

Asynchronous external aborts on instruction fetches are reported as SError interrupts using the Data Abort exception, see [Data Abort exception on page G1-3859](#).

A Prefetch Abort exception entry is synchronous to the instruction whose fetch aborted.

For more information about memory aborts see [VMSAv8-32 memory aborts on page G4-4110](#).

- A Breakpoint, Vector Catch or Breakpoint Instruction exception, see [Chapter G2 AArch32 Self-hosted Debug](#).

———— **Note** ————

If an implementation fetches instructions speculatively, it must handle a synchronous abort on such an instruction fetch by:

- Generating a Prefetch Abort exception only if the instruction would be executed in a simple sequential execution of the program.
- Ignoring the abort if the instruction would not be executed in a simple sequential execution of the program.

By default, when EL1 is using AArch32, a Prefetch Abort exception is taken to Abort mode, but a Prefetch Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see [The PE mode to which the Prefetch Abort exception is taken on page G1-3858](#).

The preferred return address for a Prefetch Abort exception is the address of the aborted instruction. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - SPSR_abt and LR_abt if returning from Abort mode.
 - SPSR_mon and LR_mon if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32](#) on page G1-3834.

Prefetch Abort exception reporting a PC alignment fault exception

A PC alignment fault exception that is taken to an Exception level that is using AArch32 is reported as a Prefetch Abort exception, and:

If the exception is taken to EL1 using AArch32 or EL3 using AArch32

- The IFSR indicates the cause of the exception:
 - If the value of `TTBCR.EAE` is 0, `IFSR.FS` takes the value `0b00001`.
 - If the value of `TTBCR.EAE` is 1, `IFSR.STATUS` takes the value `0b10001`.
- `IFAR` holds the value of the address that faulted, including the misaligned low order bit or bits.
- `R14_abt` holds the address that faulted, including the misaligned low order bit or bits, with the standard offset for a Prefetch Abort exception.

If the exception is taken to EL2 using AArch32

- `HSR.EC` takes the value `0b100010`.
- `HSR.IL` is UNKNOWN.
- `HSR.ISS` is RES0.
- `HIFAR` and `ELR_hyp` each hold the value of the address that faulted, including the misaligned low order bit or bits.

For a PC alignment fault exception taken to an Exception level that is using AArch32:

- If the exception occurred because of the CONSTRAINED UNPREDICTABLE behavior of a branch to an unaligned PC value, as described in [Branching to an unaligned PC](#) on page K1-5458, then bit[0] of the faulting address is forced to zero, and therefore the misalignment is because the value of bit[1] of this address is 1.
- If the exception occurred on an exit from Debug state, as described in [Exiting Debug state](#) on page H2-4880, then it is CONSTRAINED UNPREDICTABLE whether bit[0] of the faulting address is forced to zero.

The PE mode to which the Prefetch Abort exception is taken

Figure G1-7 shows how the implementation, state, and configuration options determine the PE mode to which a Prefetch Abort exception is taken.

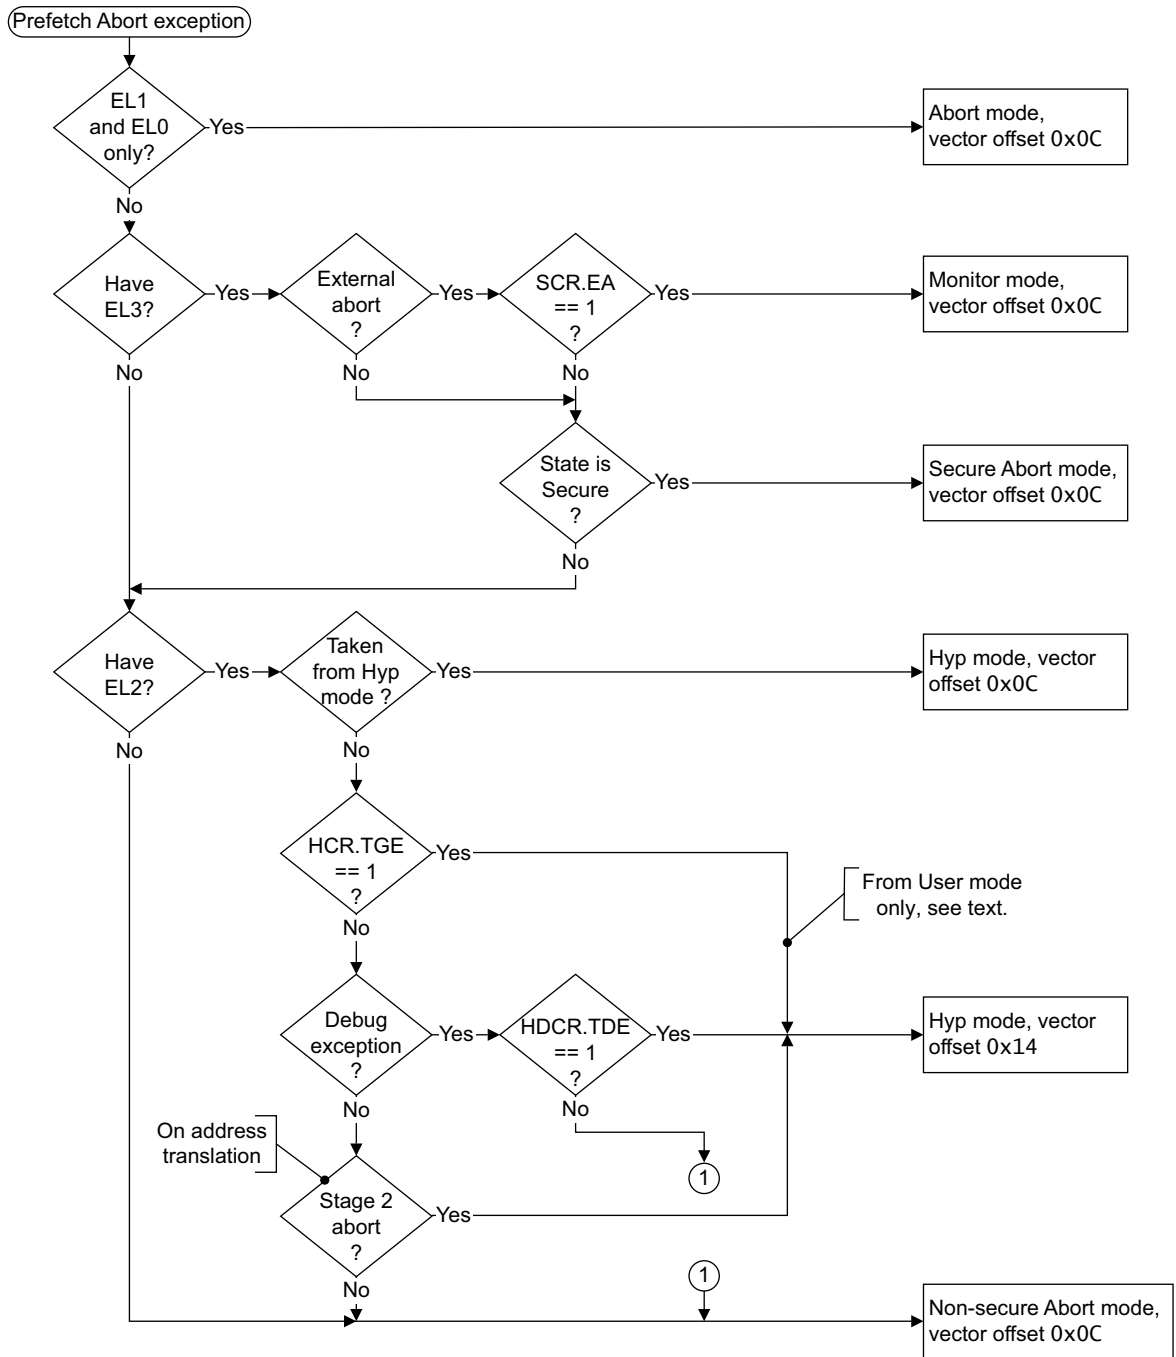

Figure G1-7 The PE mode the Prefetch Abort exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3826.

Pseudocode description of taking the Prefetch Abort exception

The `AArch32.TakePrefetchAbortException()` pseudocode procedure describes how the PE takes the exception.

G1.15.8 Data Abort exception

A Data Abort exception can be generated by:

- A synchronous abort on a data read or write memory access. Exception entry is synchronous to the instruction that generated the memory access.
- An SError interrupt. The SError interrupt might be caused by an external abort on a memory access, which can be any of:
 - A data read or write access.
 - An instruction fetch.
 - In a VMSA memory system, a translation table access.

Exception entry occurs asynchronously.

As described in [Asynchronous exception masking controls on page G1-3842](#), SError interrupts can be masked. When this happens, a generated SError interrupt is not taken until it is not masked.

- A watchpoint, see [Watchpoint exceptions on page G2-3961](#).

By default, when EL1 is using AArch32 a Data Abort exception is taken to Abort mode, but a Data Abort exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information see [The PE mode to which the Data Abort exception is taken on page G1-3860](#).

For more information about memory aborts see [VMSAv8-32 memory aborts on page G4-4110](#).

The preferred return address for a Data Abort exception is the address of the instruction that generated the aborting memory access, or the address of the instruction following the instruction boundary at which an SError interrupt exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and LR values generated by the exception entry, using an exception return instruction with a subtraction of 8. This means using:
 - [SPSR_abt](#) and [LR_abt](#) if returning from Abort mode.
 - [SPSR_mon](#) and [LR_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

The PE mode to which the Data Abort exception is taken

Figure G1-8 shows the determination of the mode to which a Data Abort exception is taken.

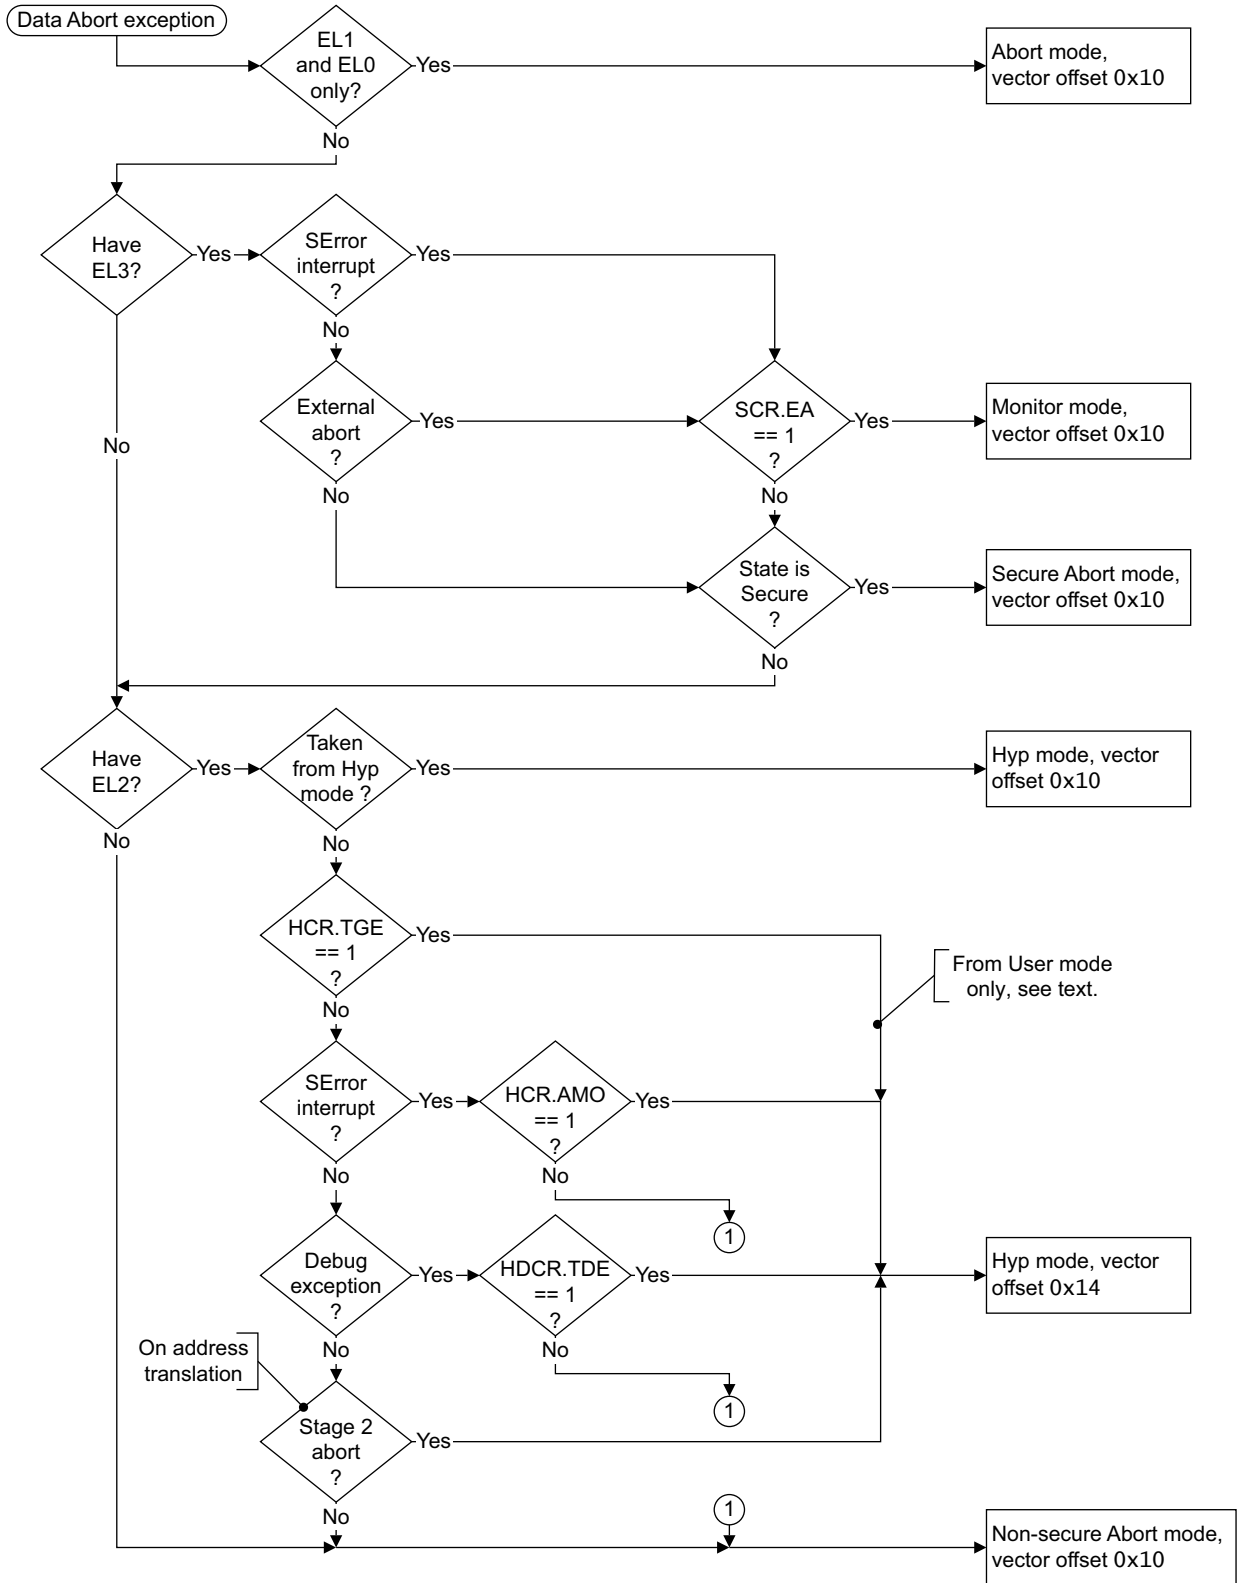

Figure G1-8 The PE mode the Data Abort exception is taken to

See also *UNPREDICTABLE cases when the value of HCR.TGE is 1* on page G1-3826.

Pseudocode description of taking the Data Abort exception

The `AArch32.TakeDataAbortException()` pseudocode procedure describes how the PE takes the exception.

Effects of data-aborted instructions

An instruction that accesses data memory can modify memory by storing one or more values. If the execution of such an instruction generates a Data Abort exception, or causes Debug state entry because of a watchpoint set on the instruction, the value of each memory location that the instruction stores to is:

- Unchanged for any location for which one of the following applies:
 - An MMU fault is generated.
 - A Watchpoint is generated.
 - An external abort is generated, if that external abort is taken synchronously.
- UNKNOWN for any location for which no exception and no debug event is generated.

If the access to a memory location generates an external abort that is taken asynchronously, it is outside the scope of the architecture to define the effect of the store on that memory location, because this depends on the system-specific nature of the external abort. However, in general, ARM recommends that such locations are unchanged.

For external aborts and Watchpoints, where in principle faulting could be identified at byte or halfword granularity, the size of a location in this definition is the size for which a memory access is single-copy atomic.

In AArch32 state, instructions that access data memory can modify registers in the following ways:

- By loading values into one or more of the general-purpose registers. The registers loaded can include the PC.
- By loading values into one or more of the registers in the Advanced SIMD and floating-point register file.
- By specifying *base register writeback*, in which the base register used in the address calculation has a modified value written to it. All instructions that support base register writeback have CONstrained UNPREDICTABLE results if base register writeback is specified with the PC as the base register. Only general-purpose registers can be modified reliably in this way.
- By a direct or indirect write to one or more System registers, for example:
 - An LDC instruction that writes to `DBGDTRTXint` using a value read from memory is a *direct write* to the System register `DBGDTRTXint`.
 - An STC instruction that reads `DBGDTRRXint` makes an *indirect write* to `DBGDSCRint.RXfull`.
- By modifying `PSTATE`.

If the execution of such an instruction generates a synchronous Data Abort exception, the following rules determine the values left in these registers:

- On entry to the Data Abort exception handler:
 - The PC value is the Data Abort vector address, see *Exception vectors and the exception base address* on page G1-3812.
 - The `LR_abt` value is determined from the address of the aborted instruction.
 Neither value is affected by the results of any load specified by the instruction.
- The base register is restored to its original value if either:
 - The aborted instruction is a load and the list of registers to be loaded includes the base register.
 - The base register is being written back.
- If the instruction only loads one general-purpose register the value in that register is unchanged.
- If the instruction loads more than one general-purpose register, UNKNOWN values are left in destination registers other than the PC and the base register of the instruction.

- If the instruction affects any registers in the Advanced SIMD and floating-point register file, UNKNOWN values are left in the registers that are affected.
- **PSTATE** bits that are not defined as updated on exception entry retain their current value.
- If the instruction is a STREX, STREXB, STREXH, or STREXD, <Rd> is not updated.

After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN. Therefore, ARM strongly recommends that the abort handler performs a CLREX instruction, or a dummy STREX instruction, to clear the exclusive monitor state.

The ARM abort model

The abort model used by an ARM PE is described as a *Base Restored Abort Model*. This means that if a synchronous Data Abort exception is generated by executing an instruction that specifies base register writeback, the value in the base register is unchanged.

The abort model applies uniformly across all instructions.

G1.15.9 Virtual SError interrupt exception

The Virtual SError interrupt exception is implemented only as part of EL2.

A Virtual SError interrupt exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of **PSTATE.A** is 0.
- Either:
 - EL2 is using AArch32 and the values of the **HCR**.{TGE, AMO, VA} bits are {0, 1, 1}.
 - EL2 is using AArch64 and the values of the **HCR_EL2**.{TGE, AMO, VA} bits are {0, 1, 1}.

The conditions for generating a Virtual SError interrupt exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure Abort mode.

For more information see [Virtual exceptions when an implementation includes EL2](#) on page G1-3839.

———— Note —————

Because the Virtual SError interrupt exception is always taken to Non-secure Abort mode, on exception entry the preferred return address is always saved to LR_abt.

The preferred return address for a Virtual SError interrupt exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the **SPSR** and LR_abt values generated by the exception entry, using an exception return instruction without subtraction.

The PE mode to which the Virtual SError interrupt exception is taken

The Virtual SError interrupt exception is supported only as part of EL2. A Virtual SError interrupt exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure Abort mode, using a vector offset of 0x10 from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2](#) on page G1-3839.

Pseudocode description of taking the Virtual SError interrupt exception

The `AArch32.TakeVirtualSErrorException()` pseudocode procedure describes how the PE takes the exception.

G1.15.10 IRQ exception

The IRQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an IRQ interrupt request input to the PE.

When an IRQ exception is taken, exception entry is precise to an instruction boundary.

As described in *Asynchronous exception masking controls* on page G1-3842, IRQ exceptions can be masked. When this happens, a generated IRQ exception is not taken until it is not masked.

By default, when EL1 is using AArch32, an IRQ exception is taken to IRQ mode, but an IRQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see *The PE mode to which the physical IRQ exception is taken*.

The preferred return address for an IRQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the *SPSR* and *LR* values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - *SPSR_irq* and *LR_irq* if returning from IRQ mode.
 - *SPSR_mon* and *LR_mon* if returning from Monitor mode.
- If returning from Hyp mode, using the *SPSR_hyp* and *ELR_hyp* values generated by the exception entry, using an *ERET* instruction.

For more information, see *Exception return to an Exception level using AArch32* on page G1-3834.

The PE mode to which the physical IRQ exception is taken

Figure G1-9 on page G1-3864 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken.

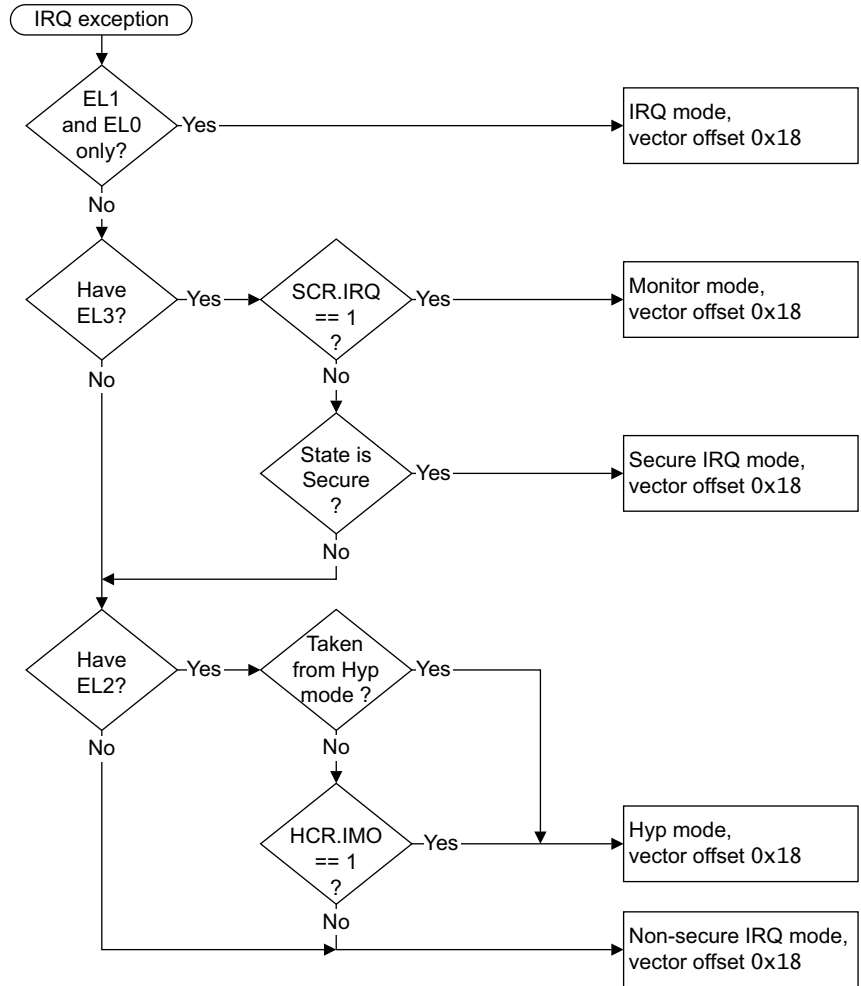

Figure G1-9 The PE mode the IRQ exception is taken to

Pseudocode description of taking the IRQ exception

The [AArch32.TakePhysicalIRQException\(\)](#) pseudocode procedure describes how the PE takes the exception.

G1.15.11 Virtual IRQ exception

The Virtual IRQ exception is implemented only as part of EL2.

A Virtual IRQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of [PSTATE.I](#) is 0.
- Either:
 - EL2 is using AArch32 and the value of [HCR.{TGE, IMO}](#) is {0, 1}.
 - EL2 is using AArch64 and the value of [HCR_EL2.{TGE, IMO}](#) is {0, 1}.
- One of the following applies:
 - EL2 is using AArch32 and the value of [HCR.VI](#) is 1.
 - EL2 is using AArch64 and the value of [HCR_EL2.VI](#) is 1.
 - A Virtual IRQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual IRQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure IRQ mode.

For more information see [Virtual exceptions when an implementation includes EL2 on page G1-3839](#).

The preferred return address for a Virtual IRQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the [SPSR](#) and [LR_irq](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception is supported only as part of EL2. A Virtual IRQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure IRQ mode, using a vector offset of 0x18 from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2 on page G1-3839](#).

Pseudocode description of taking the Virtual IRQ exception

The [AArch32.TakeVirtualIRQException\(\)](#) pseudocode procedure describes how the PE takes the exception.

G1.15.12 FIQ exception

The FIQ exception is generated by IMPLEMENTATION DEFINED means. Typically this is by asserting an FIQ interrupt request input to the PE.

When an FIQ exception is taken, exception entry is precise to an instruction boundary.

As described in [Asynchronous exception masking controls on page G1-3842](#), FIQ exceptions can be masked. When this happens, a generated FIQ exception is not taken until it is not masked.

By default, an FIQ exception is taken to FIQ mode, but an FIQ exception can be taken to:

- EL2, meaning it is taken to Hyp mode if EL2 is using AArch32.
- EL3, meaning it is taken to Monitor mode if EL3 is using AArch32.

For more information, see [The PE mode to which the physical FIQ exception is taken on page G1-3866](#).

The preferred return address for an FIQ exception is the address of the instruction following the instruction boundary at which the exception was taken. This return is performed as follows:

- If returning from a mode other than Hyp mode, using the [SPSR](#) and [LR](#) values generated by the exception entry, using an exception return instruction with a subtraction of 4. This means using:
 - [SPSR_fiq](#) and [LR_fiq](#) if returning from FIQ mode.
 - [SPSR_mon](#) and [LR_mon](#) if returning from Monitor mode.
- If returning from Hyp mode, using the [SPSR_hyp](#) and [ELR_hyp](#) values generated by the exception entry, using an ERET instruction.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

The PE mode to which the physical FIQ exception is taken

Figure G1-9 on page G1-3864 shows how the implementation, state, and configuration options determine the PE mode to which an FIQ exception is taken.

Figure G1-10 The PE mode the FIQ exception is taken to

Pseudocode description of taking the FIQ exception

The `AArch32.TakePhysicalFIQException()` pseudocode procedure describes how the PE takes the exception.

G1.15.13 Virtual FIQ exception

The Virtual FIQ exception is implemented only as part of EL2.

A Virtual FIQ exception is generated if all of the following apply:

- The PE is in a Non-secure mode other than Hyp mode.
- The value of `PSTATE.F` is 0.
- Either:
 - EL2 is using AArch32 and the value of `HCR.{TGE, FMO}` is {0, 1}.
 - EL2 is using AArch64 and the value of `HCR_EL2.{TGE, FMO}` is {0, 1}.

- One of the following applies:
 - EL2 is using AArch32 and the value of `HCR.VF` is 1.
 - EL2 is using AArch64 and the value of `HCR_EL2.VF` is 1.
 - A Virtual FIQ exception is generated by an IMPLEMENTATION DEFINED mechanism.

The conditions for generating a Virtual FIQ exception mean the exception is always:

- Taken from a Non-secure EL1 or EL0 mode.
- Taken to Non-secure FIQ mode.

For more information see [Virtual exceptions when an implementation includes EL2](#) on page G1-3839.

The preferred return address for a Virtual FIQ exception is the address of the instruction immediately after the instruction boundary where the exception was taken. This return is performed using the `SPSR` and `LR_irq` values generated by the exception entry, using an exception return instruction with a subtraction of 4.

The PE mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of EL2. A Virtual FIQ exception is taken from a Non-secure EL1 or EL0 mode, and is taken to Non-secure FIQ mode, using a vector offset of `0x1C` from the Non-secure exception base address.

For more information about this exception see [Virtual exceptions when an implementation includes EL2](#) on page G1-3839.

Pseudocode description of taking the Virtual FIQ exception

The `AArch32.TakeVirtualFIQException()` pseudocode procedure describes how the PE takes the exception.

G1.15.14 Additional pseudocode functions for exception handling

The `AArch32.EnterMonitorMode()` pseudocode function changes the PE mode to Monitor mode, with the required state changes.

The `AArch32.EnterHypMode()` pseudocode function changes the PE mode to Hyp mode, with the required state changes.

The `AArch32.EnterMode()` pseudocode function changes the PE mode to a PL1 mode, with the required state changes. It is used for all exceptions that are not routed to Hyp mode or Monitor mode.

The `AArch32.EnterMonitorMode()`, `AArch32.EnterHypMode()`, and `AArch32.EnterMode()` functions are described in [Chapter J1 ARMv8 Pseudocode](#).

G1.16 Reset into AArch32 state

[Reset on page D1-1517](#) describes the ARMv8 reset model, including the defined levels of reset. When reset is deasserted, the PE starts executing instructions in the highest implemented Exception level. If that Exception level is using AArch32, then it starts execution:

- In Secure state, if the implementation includes EL3.
- With interrupts disabled:
 - In Hyp mode, if the highest implemented Exception level is EL2.
 - In Supervisor mode, otherwise.

Note

- This section describes the architectural requirements for a reset into AArch32 state. It takes no account of whether ARM licenses any particular combination of Exception levels and Execution state. For more information about the licensed combinations see [Support for Exception levels and Execution states on page D1-1620](#).
- The Execution state in which the highest implemented Execution level starts executing instructions on coming out of reset might be determined by a configuration input signal.

Reset returns some PE state to architecturally-defined or IMPLEMENTATION DEFINED values, and makes other state UNKNOWN, as described in [PE state on reset into AArch32 state on page G1-3869](#). For more information about behavior when resetting into an Exception level using AArch32, see:

- [Behavior of caches at reset on page G3-3995](#).
- [Enabling stages of address translation on page G4-4033](#).
- [TLB behavior at reset on page G4-4090](#).
- [Reset and debug on page H6-4955](#).

When reset is deasserted, if the PE resets into an Exception level that is using AArch32, it is IMPLEMENTATION DEFINED whether execution starts:

- From an IMPLEMENTATION DEFINED address.
- If reset is into EL3 or EL1, from the low or high reset vector address, as determined by the reset value of the [SCTLR.V](#) bit. This reset value can be determined by an IMPLEMENTATION DEFINED configuration input signal.

Note

This option might be implemented for compatibility with earlier versions of the architecture.

Software might be able to identify the reset address:

- If reset is into EL3, by reading the reset value of [MVBAR](#). That is, after coming out of reset, by reading [MVBAR](#) before the boot software has updated it. It is IMPLEMENTATION DEFINED whether this discovery mechanism is supported.
- If reset is into EL2 or EL1, by reading [RVBAR](#). [RVBAR](#) can only be implemented at the highest implemented Exception level, and only if that Exception level is not EL3.

If [RVBAR](#) is not implemented, and at all Exception levels other than the highest implemented Exception level, the encoding for [RVBAR](#) is UNDEFINED.

The ARM architecture does not define any way of returning to a previous Execution state from a reset.

G1.16.1 PE state on reset into AArch32 state

Note

See the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* for the reset requirements for GIC System registers.

Immediately after a reset, much of the PE state is UNKNOWN. However, some of the PE state is defined. If the PE resets to AArch32 state using either a Cold or a Warm reset, the PE state that is defined is as follows:

- If reset is into EL3 using AArch32 then all fields of the **SCR** reset to zero.

Note

This means **SCR.NS** correctly indicates that the PE is in Secure state.

- If reset is into EL2 using AArch32 then reset is into Hyp mode and **CPSR.M** resets to 0b1010, otherwise reset is into Supervisor mode and **CPSR.M** resets to 0b0011,
- **CPSR.IL** resets to 0.
- The **CPACR**.{cp11, cp10} fields reset to zero, and if **CPACR.ASEDIS** is implemented as an RW field it resets to zero.

Note

When **CPACR.TRCDIS** is a RW field, its reset value is architecturally UNKNOWN.

- **PSTATE** is reset to the values defined by the **AArch32.TakeReset()** pseudocode function, see *Pseudocode descriptions of reset on page G1-3871*.
- The **FPEXC.EN** field resets to 0.
- In the **SCTLR**:
 - The {AFE, TRE, UWXN, WXN, I, SED, ITD, C, A, M} fields reset to 0.
 - The {nTWE, nTWI, CP15BEN} fields reset to 1.
 - The {TE, EE, V} fields reset to IMPLEMENTATION DEFINED values, see the register description for more information.

When the reset is to EL3 using AArch32 then these reset values apply only to the Secure instance of the **SCTLR**, and the reset value of the Non-secure **SCTLR** is architecturally UNKNOWN.
- All field of the **TTBCR** reset to 0.

When the reset is to EL3 using AArch32 then:

 - All fields of the Secure **TTBCR** reset to 0.
 - In the Non-secure **TTBCR**, the EAE field resets to 0, and the reset values of all other fields are architecturally UNKNOWN.
- The **VBAR** resets to an IMPLEMENTATION DEFINED value.

When the reset is to EL3 using AArch32 then this reset value applies only to the Secure instance of the register, and the reset value of the Non-secure **VBAR** is architecturally UNKNOWN.
- All fields of the **DBGDCCINT** reset to 0.
- The **DBGDSCRExt**.{MDBGen, UDCCdis} fields reset to 0.
- The **DBGOSDLR**.DLK field resets to 0.

In addition:

If the reset is into EL1 using AArch32

- In the **RMR (at EL1)** register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.

If the reset is into EL2 using AArch32

- In the **HRMR**, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- The **HSCTLR**.{I, C, M} fields all reset to 0, and the **HSCTLR**.EE field resets to an IMPLEMENTATION DEFINED value.

If the reset is into EL2 using AArch32 or into EL3 using AArch32

For a reset into EL3 using AArch32 these reset values apply only if the implementation includes EL2, see the register descriptions for more information.

- All fields of the **HCPTTR** reset to zero.
- All fields of the **HCR** reset to zero.
- The **HCR2**.{ID, CD} fields reset to zero.
- All fields of the **HSTR** reset to zero.
- The **VMPIDR** resets to the value of the **MPIDR**, see the register description for more information.
- The **VPIDR** resets to the value of the **MIDR**, see the register description for more information.
- The **VTTBR**.VMID field resets to zero.
- In the **HDCR**:
 - The HPMN field resets to the IMPLEMENTATION DEFINED value of **PMCR**.N.
 - The reset value of the HPME field is architecturally UNKNOWN.
 - All other fields reset to 0.

If the reset is into EL3 using AArch32

- The **MVBAR** resets to an IMPLEMENTATION DEFINED value, see the register description for more information.
- If the **NSACR**.{NSTRCDIS, NSASEDIS} fields are RW fields then they reset to 0.
- In the **RMR (at EL3)** register, the RR field resets to 0 on any warm or cold reset, and the AA64 field resets to 0 on a cold reset.
- All fields of the **SCR** reset to zero.
- All fields of the **SDER** reset to 0.
- All fields of the **SDCR** reset to zero.

For either a warm or a cold reset

- The **EDPRSR**.SR field resets to 1.
- The **EDES**.{SS, RC, OSUC} fields reset to 0.

For a cold reset only

- The **EDSCR**.{RXO, TXU, INTdis, TDA, MA, HDE, ERR, RXfull, TXfull} fields reset to 0.
- The **EDECCR**.{NSE, SE} fields reset to 0.
- The **EDPRSR**.{SPMAD, SDAD} fields reset to 0, and the **EDPRSR**.SPD field resets to 1.
- The **DBGOSLSR**.OSLK field resets to 1.
- The **DBGPRCR**.CORENPDRQ field resets to the value of **EDPRCR**.COREPURQ.

An External Debug reset sets `EDPRCR.COREPURQ` to 0, see *External debug register resets on page H8-4981*. If an External Debug reset and a cold reset coincide, both `DBGPRCR.CORENPRDRQ` and `EDPRCR.COREPURQ` are reset to 0.

- The debug CLAIM bits are reset to 0.

———— **Note** —————

These are the bits that are set to 1 by writing to `DBGCLAIMSET.CLAIM`, and reset to 0 by writing to `DBGCLAIMCLR.CLAIM`.

—————

G1.16.2 Pseudocode descriptions of reset

The `AArch32.TakeReset()` pseudocode procedure describes how the PE behaves when reset is deasserted.

The `AArch32.ResetGeneralRegisters()` pseudocode function resets the general-purpose registers.

The `AArch32.ResetSIMDFPRegisters()` pseudocode function resets the SIMD and floating-point registers.

The `AArch32.ResetSpecialRegisters()` pseudocode function resets the Special-purpose registers, and the debug System registers `DLR` and `DSPSR`, that are used for handling Debug exceptions.

The `AArch32.ResetSystemRegisters()` pseudocode function resets all System registers in the (coproc==0b111x) encoding space to their reset state as defined in the register descriptions in *Chapter G6 AArch32 System Register Descriptions*.

———— **Note** —————

The `ResetSystemRegisters()` function only resets the System registers. It has no effect on memory-mapped registers.

—————

The `ResetExternalDebugRegisters()` pseudocode function resets all external debug registers to their reset state as defined in the register descriptions in *Chapter H9 External Debug Register Descriptions*.

G1.17 Mechanisms for entering a low-power state

The following sections describe the architectural mechanisms that a PE can use to request entry to a low-power state:

- [Wait For Event and Send Event](#).
- [Wait For Interrupt](#) on page G1-3875.

G1.17.1 Wait For Event and Send Event

The Wait For Event (WFE) mechanism permits a PE to request entry to a low-power state, and, if the request succeeds, to remain in that state until an event is generated by a Send Event operation, or another WFE wake-up event occurs. [Example G1-2](#) describes how a spinlock implementation might use this mechanism to save energy.

Example G1-2 Spinlock as an example of using Wait For Event and Send Event

A multiprocessor operating system requires locking mechanisms to protect data structures from being accessed simultaneously by multiple PEs. These mechanisms prevent the data structures becoming inconsistent or corrupted if different PEs try to make conflicting changes. If a lock is busy, because a data structure is being used by one PE, it might not be practical for another PE to do anything except wait for the lock to be released. For example, if a PE is handling an interrupt from a device it might need to add data received from the device to a queue. If another PE is removing data from the queue, it will have locked the memory area that holds the queue. The first PE cannot add the new data until the queue is in a consistent state and the lock has been released. It cannot return from the interrupt handler until the data has been added to the queue, so it must wait.

Typically, a spin-lock mechanism is used in these circumstances:

- A PE requiring access to the protected data attempts to obtain the lock using single-copy atomic synchronization primitives such as the Load-Exclusive and Store-Exclusive operations described in [Synchronization and semaphores](#) on page E2-2355.
- If the PE obtains the lock it performs its memory operation and releases the lock.
- If the PE cannot obtain the lock, it reads the lock value repeatedly in a tight loop until the lock becomes available. At this point it again attempts to obtain the lock.

A spin-lock mechanism is not ideal for all situations:

- In a low-power system the tight read loop is undesirable because it uses energy to no effect.
- In a multithreaded implementation the execution of spin-locks by waiting threads can significantly degrade overall performance.

Using the Wait For Event and Send Event mechanism can improve the energy efficiency of a spinlock. In this situation, a PE that fails to obtain a lock can execute a Wait For Event instruction, WFE, to request entry to a low-power state. When a PE releases a lock, it must execute a Send Event instruction, SEV, causing any waiting PEs to wake up. Then, these PEs can attempt to gain the lock again.

The execution of a WFE instruction can cause suspension of execution only if all of the following are true:

- The instruction does not cause any other exception.
- When the instruction is executed:
 - The Event Register is not set.
 - There is not a pending WFE wakeup event.

For more information about the trap to EL2 see [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions](#) on page G1-3904.

The architecture does not define the exact nature of the low power state entered as a result of executing a WFE instruction, but the execution of a WFE instruction must not cause a loss of memory coherency.

———— **Note** —————

Although a complex operating system can contain thousands of distinct locks, the event sent by this mechanism does not indicate which lock has been released. If the event relates to a different lock, or if another PE acquires the lock more quickly, the PE fails to acquire the lock and can reenter the low-power state waiting for the next event.

The Wait For Event system relies on hardware and software working together to achieve energy saving:

- The hardware provides the mechanism to enter the Wait For Event low-power state.
- The operating system software is responsible for issuing:
 - A Wait For Event instruction, to request entry to the low-power state, used in the example when waiting for a spin-lock.
 - A Send Event instruction, required in the example when releasing a spin-lock.

The mechanism depends on the interaction of:

- WFE wake-up events, see [WFE wake-up events on page G1-3874](#).
- The Event Register, see [The Event Register](#).
- The Send Event instructions, see [The Send Event instructions on page G1-3874](#).
- The Wait For Event instruction, see [The Wait For Event instruction](#).

The Event Register

The Event Register is a single bit register for each PE. When set, an event register indicates that an event has occurred, since the register was last cleared, that might require some action by the PE. Therefore, the PE must not suspend operation on issuing a WFE instruction.

The reset value of the Event Register is UNKNOWN.

The Event Register for a PE is set by:

- The execution of an SEV instruction on any PE in the multiprocessor system.
- The execution of an SEVL instruction by the PE.
- An exception return.
- An event from a Generic Timer event stream, see [Event streams on page G5-4223](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.

As shown in this list, the Event Register might be set by IMPLEMENTATION DEFINED mechanisms.

The Event Register is cleared only by a Wait For Event instruction.

Software cannot read or write the value of the Event Register directly.

The Wait For Event instruction

The action of the Wait For Event instruction depends on the state of the Event Register:

- If the Event Register is set, the instruction clears the register and completes immediately. Normally, if this happens the software makes another attempt to claim the lock.
- If the Event Register is clear the PE can suspend execution, and hardware might enter a low-power state. The PE can remain suspended until a WFE wake-up event or a reset occurs. When a WFE wake-up event occurs, or earlier if the implementation chooses, the WFE instruction completes.

The execution in AArch32 state of a WFE instruction that would otherwise cause suspension of execution might be trapped, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-3888](#).
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3904](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-3915](#).

The Wait For Event instruction, WFE, is available at all privilege levels, see [WFE on page F5-3222](#).

Software using the Wait For Event mechanism must tolerate spurious wake-up events, including multiple wake ups.

WFE wake-up events

The following events are *WFE wake-up events*:

- The execution of an SEV instruction on any PE in the system.
- The execution of an SEVL instruction on the PE.
- A physical IRQ interrupt, unless masked by the [PSTATE.I](#) bit.
- A physical FIQ interrupt, unless masked by the [PSTATE.F](#) bit.
- A physical SError interrupt, unless masked by the [PSTATE.A](#) bit.
- In Non-secure state in any mode other than Hyp mode:
 - When [HCR.IMO](#) is set to 1, a virtual IRQ interrupt, unless masked by the [PSTATE.I](#) bit.
 - When [HCR.FMO](#) is set to 1, a virtual FIQ interrupt, unless masked by the [PSTATE.F](#) bit.
 - When [HCR.AMO](#) is set to 1, a virtual SError interrupt, unless masked by the [PSTATE.A](#) bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see [Halting allowed and halting prohibited on page H2-4845](#).
See also [External Debug Request debug event on page H3-4900](#).
- An event sent by the timer event stream, see [Event streams on page D6-1882](#).
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- An event caused by the clearing of the global monitor associated with the PE.

In addition to the possible masking of WFE wake-up events shown in this list, when invasive debug is enabled and [EDSCR.HDE](#) is set to 1, [EDSCR.INTdis](#) can mask interrupts, including masking them acting as WFE wake-up events. For more information, see [EDSCR, External Debug Status and Control Register on page H9-5064](#).

As shown in the list of wake-up events, an implementation can include IMPLEMENTATION DEFINED hardware mechanisms to generate wake-up events.

———— Note —————

For more information about [PSTATE](#) masking see [Asynchronous exception masking controls on page G1-3842](#). If the configuration of the masking controls provided by EL2 and EL3 mean that a [PSTATE](#) mask bit cannot mask the corresponding exception, then the physical exception is a WFE wake-up event, regardless of the value of the [PSTATE](#) mask bit.

The Send Event instructions

The Send Event instructions are:

SEV, Send Event This causes an event to be signaled to all PEs in the multiprocessor system.

SEVL, Send Event Local

This must set the local Event Register. It might signal an event to other PEs, but is not required to do so.

The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED. The PE is not required to guarantee the ordering of this event with respect to the completion of memory accesses by instructions before the SEV instruction. Therefore, ARM recommends that software includes a DSB instruction before any SEV instruction.

———— Note —————

A DSB instruction ensures that no instruction, including any SEV instruction, that appears in program order after the DSB instruction, can execute until the DSB instruction has completed. For more information, see [Data Synchronization Barrier \(DSB\) on page E2-2337](#).

The SEVL instruction appears to execute in program order relative to any subsequent WFE instruction executed on the same PE, without the need for any explicit insertion of barrier instructions.

Execution of the Send Event instruction sets the Event Register.

The Send Event instructions are available at all privilege levels.

Pseudocode description of the Wait For Event mechanism

This section defines pseudocode functions that describe the operation of the Wait For Event mechanism.

The `ClearEventRegister()` pseudocode procedure clears the Event Register of the current PE.

The `EventRegistered()` pseudocode function returns TRUE if the Event Register of the current PE is set and FALSE if it is clear.

The `WaitForEvent()` pseudocode procedure optionally suspends execution until a WFE wake-up event or reset occurs, or until some earlier time if the implementation chooses. It is IMPLEMENTATION DEFINED whether restarting execution after the period of suspension causes a `ClearEventRegister()` to occur.

The `SendEvent()` pseudocode procedure sets the Event Register of every PE in the system.

G1.17.2 Wait For Interrupt

AArch32 state supports Wait For Interrupt through an instruction, WFI, that is provided in the A32 and T32 instruction sets. For more information, see [WFI on page F5-3224](#).

When a PE issues a WFI instruction, its execution can be suspended, and a low-power state can be entered.

The execution in AArch32 state of a WFI instruction that would otherwise cause suspension of execution might be trapped, see:

- [Traps to Undefined mode of ELO execution of WFE and WFI instructions on page G1-3888](#).
- [Traps to Hyp mode of Non-secure ELO and EL1 execution of WFE and WFI instructions on page G1-3904](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-3915](#).

The execution of a WFI instruction can cause suspension of execution only if both:

- The instruction does not cause any other exception.
- When the instruction is executed, there is not a pending WFI wakeup event.

WFI wake-up events

The PE can remain suspended in its WFI state until it is reset, or one of the following *WFI wake-up events* occurs:

- A physical IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
- A physical FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
- A physical SError interrupt, regardless of the value of the `PSTATE.A` bit.
- In Non-secure state in any mode other than Hyp mode:
 - When `HCR.IMO` is set to 1, a virtual IRQ interrupt, regardless of the value of the `PSTATE.I` bit.
 - When `HCR.FMO` is set to 1, a virtual FIQ interrupt, regardless of the value of the `PSTATE.F` bit.
 - When `HCR.AMO` is set to 1, a virtual SError interrupt, regardless of the value of the `PSTATE.A` bit.
- An asynchronous External Debug Request debug event, if halting is allowed. For the definition of *halting is allowed* see [Halting allowed and halting prohibited on page H2-4845](#).
See also [External Debug Request debug event on page H3-4900](#).

An implementation can include other IMPLEMENTATION DEFINED hardware mechanisms to generate WFI wake-up events.

When a WFI wake-up event is detected, or earlier if the implementation chooses, the WFI instruction completes.

WFI wake-up events cannot be masked by the mask bits in the `PSTATE`.

The architecture does not define the exact nature of the low power state, but the execution of a WFI instruction must not cause a loss of memory coherency.

Note

- Because debug events are WFI wake-up events, ARM strongly recommends that is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures the intervention of debug while waiting does not significantly change the function of the program being debugged.
- In some previous implementations of Wait For Interrupt, the idle loop is followed by exit functions that must be executed before taking the interrupt. The operation of Wait For Interrupt remains consistent with this model, and therefore differs from the operation of Wait For Event.
- Some implementations of Wait For Interrupt drain down any pending memory activity before suspending execution. The ARM architecture does not require this operation, and software must not rely on Wait For Interrupt operating in this way.

Using WFI to indicate an idle state on bus interfaces

A common implementation practice is to complete any entry into powerdown routines with a WFI instruction.

Typically, the WFI instruction:

1. Forces the completion of execution of any instructions that are in progress, and of all associated bus activity.
2. Suspends the execution of instructions by the PE.

The control logic required to do this tracks the activity of the bus interfaces used by the PE. This means it can signal to an external power controller when there is no ongoing bus activity.

However, memory-mapped and external debug interface accesses to debug registers must continue to be processed while the PE is in the WFI state. The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

When the value of `DBGOSDLR.DLK`, the OS Double Lock status bit, is set to 1, this idle state must not be signaled to the PE unless the system can guarantee, also, that the debug interface is idle.

Note

When separate core and debug power domains are implemented, the debug interface referred to in this section is the interface between the core and debug power domains, since the signal to the power controller indicates that the core power domain is idle. For more information about the power domains see [Power domains and debug on page H6-4945](#).

The exact nature of this interface is IMPLEMENTATION DEFINED, but the use of Wait For Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it very suitable as the preferred powerdown entry mechanism.

Pseudocode description of Wait For Interrupt

The `WaitForInterrupt()` pseudocode function optionally suspends execution until a WFI wake-up event or reset occurs, or until some earlier time if the implementation chooses.

G1.18 The AArch32 System register interface

In ARMv8, most system registers are accessed using the instructions described in *System register access instructions* on page F1-2387. The System register interface provides access to those instructions, and:

- These registers are encoded using the parameters {coproc, opc1, CRn, CRm, opc2}, with permitted coproc values of 0b1110 and 0b1111.
- Some of these encodings provide the AArch32 System instructions summarized in:
 - *Cache maintenance instructions, functional group* on page G4-4201.
 - *TLB maintenance instructions, functional group* on page G4-4202.
 - *Address translation instructions, functional group* on page G4-4204.
- To maintain compatibility with previous versions of the ARM architecture, the access controls for the AArch32 System registers include the access controls for AArch32 Advanced SIMD and floating-point functionality.

———— **Note** —————

See *Background to the System register interface* on page G1-3879 for more information.

The following sections give more information about the AArch32 System register interface:

- *System registers in the coproc == 0b111x encoding space.*
- *Access to System registers.*
- *Access controls for Advanced SIMD and floating-point functionality* on page G1-3878.
- *Pseudocode description of checking accesses to the System registers* on page G1-3878.

G1.18.1 System registers in the coproc == 0b111x encoding space

In AArch32 state:

- The coproc == 0b1110 encoding space is reserved for the configuration and control of:
 - Debug features, see *Debug registers* on page G6-4668.
 - Trace features, see the *Embedded Trace Macrocell Architecture Specification*.
 - Identification registers for the Trivial Jazelle implementation, see *Trivial implementation of the Jazelle extension* on page G1-3810.
- The coproc == 0b1111 encoding space is reserved for the control and configuration of the PE, including architecture and feature identification. This means these encodings provide access to the System registers that control and return status information for PE operation.

For more information see *Chapter G6 AArch32 System Register Descriptions*.

G1.18.2 Access to System registers

Most System registers are accessible only from EL1 or higher. For possible accesses from EL0:

- The register descriptions in *Chapter G6 AArch32 System Register Descriptions* indicate whether a register is accessible from EL0.
- *PL0 views of the System registers in the (coproc==0b1111) encoding space* on page G4-4190 summarizes the permitted accesses to System registers in the coproc == 0b1111 encoding space from EL0.

G1.18.3 Access controls for Advanced SIMD and floating-point functionality

In ARMv8, the **CPACR** controls access to Advanced SIMD and floating-point functionality from software executing at PL1 or EL0 in AArch32 state:

- The {cp10, cp11} fields control access to all Advanced SIMD and floating-point functionality, and can:
 - Disable EL0 and PL1 access to this functionality.
 - Enable access to this functionality at PL1 only.
 - Enable access to this functionality at EL0 and PL1.
- The **ASEDIS** field controls access to Advanced SIMD instructions that are not also floating-point instructions.

Initially on powerup or reset into AArch32 state, all access to all Advanced SIMD and floating-point functionality from PL1 and EL0 is disabled.

———— **Note** —————

The **CPACR** has no effect on accesses from Hyp mode.

If an implementation includes EL3, the **NSACR** determines whether Advanced SIMD and floating-point functionality can be accessed from Non-secure state:

- The {cp10, cp11} fields control Non-secure access to all Advanced SIMD and floating-point functionality.
- The **NSASEDIS** field controls Non-secure access to Advanced SIMD instructions that are not also floating-point instructions.

If an implementation includes EL2, the **HCPTR** provides additional controls on Non-secure accesses to Advanced SIMD and floating-point functionality. For accesses that are otherwise permitted by the **CPACR** and **NSACR** settings, setting **HCPTR** bits to 1:

- Traps otherwise-permitted accesses from EL1 or EL0 to EL2. When EL2 is using AArch32, these accesses are trapped to Hyp mode.
- Makes accesses from EL2 mode UNDEFINED. When EL2 is using AArch32, this makes accesses from Hyp mode UNDEFINED.

In the **HCPTR**:

- The {TCP10, TCP11} fields control access to all Advanced SIMD and floating-point functionality.
- The **TASE** field controls access to Advanced SIMD instructions that are not also floating-point instructions.
- The **TCPAC** field traps Non-secure EL1 accesses to the **CPACR** to Hyp mode.

For more information, see *General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers* on page G1-3905.

———— **Note** —————

Whenever a pair of fields control the access to the Advanced SIMD and floating-point functionality, the values of each field of the pair must be identical. In ARMv8, if these settings are not identical the behavior of the Advanced SIMD and floating-point functionality is **CONSTRAINED UNPREDICTABLE**, see *Handling of System register control fields for Advanced SIMD and floating-point operation* on page K1-5462.

For more information about Advanced SIMD and floating-point support see *Advanced SIMD and floating-point support* on page G1-3880.

G1.18.4 Pseudocode description of checking accesses to the System registers

The **AArch32.CheckSystemAccess()** function determines whether a System register access instruction that targets a System register in the (coproc == 0b111x) encoding space is accepted.

G1.18.5 Background to the System register interface

Note

This section is not part of the ARMv8 Architecture specification. It is included only to present the rationale of some aspects of the System register interface.

The interface to the System registers was originally defined as part of a generic *coprocessor* interface, that gave access to fifteen coprocessors, CP0 - CP15. Of these, CP8 - CP15 were reserved for use by ARM, while CP0 - CP7 were available for IMPLEMENTATION DEFINED coprocessors.

The coprocessors were accessed using coprocessor instructions. These instructions remain part of the T32 and A32 instruction sets, see [System register access instructions on page F1-2387](#).

In the ARM coprocessor model, a coprocessor included both:

- Primary and secondary coprocessor registers, that form part of the coprocessor interface.
- A number of internal registers.

When accessing a 32-bit internal coprocessor register, using an MCR or MRC instruction, the instruction specified:

- The target coprocessor, specified by the coproc parameter and taking a value between p0 for CP0 and p15 for CP15.
- The primary coprocessor register, specified by the CRn parameter and taking a value between c0 and c15.
- The secondary coprocessor register, specified by the CRm parameter and taking a value between c0 and c15.
- Up to two additional parameters, opc1 and opc2, taking values between 0 and 7.

To maintain backwards compatibility, the arguments to an MCR or MRC instruction remain {coproc, opc1, CRn, CRm, opc2}. Similarly, the encoding of the AArch64 System registers is described using the parameters {op0, op1, CRn, CRm, op2}. However the naming of these parameters no longer has any particular significance.

Of the coprocessors reserved for use by ARM:

- CP15 provided access to the System registers relating to non-debug operation, and was originally called the System control coprocessor. In ARMv8 these registers are described as being in the coproc == 0b1111 encoding space.
- CP14 provided access to additional System registers, including those relating to debug and trace. In ARMv8 these registers are described as being in the coproc == 0b1110 encoding space.
- CP10 and CP11 were used for Advanced SIMD and floating-point control, and many coprocessor instruction encodings targeting CP10 and CP11 were used as floating-point instruction encodings:
 - Generally ARMv8 does not relate these instructions to the coprocessor encoding space, but the naming of registers and register fields for Advanced SIMD and floating-point control reflects the historic coprocessor model.
 - Because the Advanced SIMD and floating-point functionality used both CP10 and CP11, some System register controls of this functionality have a pair of fields, for example NSACR.{cp10, cp11}. In these cases, both fields must be set to the same value. For more information see [Access controls for Advanced SIMD and floating-point functionality on page G1-3878](#).

In ARMv8, the AArch32 System registers include registers that were described as Special registers in ARMv7 and earlier versions of the architecture. This means that the ARMv8 System registers include registers that are outside the earlier coprocessor model.

G1.19 Advanced SIMD and floating-point support

[Advanced SIMD and floating-point instructions on page E1-2300](#) introduces:

- The scalar floating-point instructions in the A32 and T32 instruction sets.
- The Advanced SIMD integer and floating-point vector instructions in the A32 and T32 instruction sets.
- The SIMD and floating-point register file, that can be viewed as:
 - Singleword registers S0 - S31.
 - Doubleword registers D0 - D31.
 - Quadword registers Q0 - Q15.
- The *Floating-Point Status and Control Register (FPSCR)*.

For more information about the System registers for the Advanced SIMD and floating-point operation see [Advanced SIMD and floating-point System registers on page G1-3882](#). Software can interrogate these registers to discover the implemented Advanced SIMD and floating-point support.

[AArch32 implications of not including support for Advanced SIMD and floating-point](#) summarizes the effects of not supporting these instructions, and the following subsections give more information about the Advanced SIMD and Floating-point support:

- [Enabling Advanced SIMD and floating-point support on page G1-3881](#).
- [Advanced SIMD and floating-point System registers on page G1-3882](#).
- [Context switching when using Advanced SIMD and floating-point functionality on page G1-3883](#).
- [Floating-point exception traps on page G1-3883](#).

G1.19.1 AArch32 implications of not including support for Advanced SIMD and floating-point

As stated in [Implementations not including Advanced SIMD and floating-point instructions on page D1-1621](#), although ARMv8-A generally requires the inclusion of the Advanced SIMD and floating-point instructions in all instruction sets, for implementations targeting specialized markets, ARM might produce or license ARMv8-A implementations that do not provide any support for Advanced SIMD and floating-point instructions. In such an implementation, in AArch32 state:

- The **CPACR**.{ASEDIS, cp11, cp10} fields are RES0.
- The **NSACR**.{NSASEDIS, cp11, cp10} fields are RES0.
- The **HCPTR**.{TASE, TCP11, TCP10} fields are RES1.
- The **FPEXC**, **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, and **MVFR2** registers are not implemented and their encodings are UNDEFINED.
- Attempted accesses to Advanced SIMD and floating-point functionality are UNDEFINED. This means:
 - All Advanced SIMD and floating-point instructions are UNDEFINED.
 - Attempts to access the Advanced SIMD and floating-point System registers are UNDEFINED.

G1.19.2 Enabling Advanced SIMD and floating-point support

Software must ensure that the required access to the Advanced SIMD and floating-point features is enabled. Most of those controls are described in [Configurable instruction enables and disables, and trap controls on page G1-3885](#), and this section:

- Summarizes those controls.
- Provides additional information in the following subsections:
 - [FPExc control of access to Advanced SIMD and floating-point functionality on page G1-3882](#).
 - [EL0 access to Advanced SIMD and floating-point functionality on page G1-3882](#).

Note

This section shows the controls when the controlling Exception levels are using AArch32. Similar controls are provided when the Exception levels are using AArch64, and then apply to lower Exception levels that are using AArch32.

The controls of access to Advanced SIMD and floating-point functionality are:

General {cp10, cp11} or {TCP10, TCP11} controls

This relates to the [CPACR](#).{cp10, cp11}, [NSACR](#).{cp10, cp11}, and [HCPTR](#).{TCP10, TCP11} controls.

Note

[Background to the System register interface on page G1-3879](#) explains the naming of these controls.

The {cp10, cp11} controls provide general control of the use of Advanced SIMD and floating-point functionality, as follows:

- [CPACR](#).{cp10, cp11} control access from PE modes other than Hyp mode. These fields have no effect on accesses to Advanced SIMD and floating-point functionality from Hyp mode.
- In an implementation that includes EL3, [NSACR](#).{cp10, cp11} control access from Non-secure state.
- In an implementation that includes EL2, if [NSACR](#).{cp10, cp11} permit Non-secure accesses, or if EL3 is not implemented, [HCPTR](#).{TCP10, TCP11} provide an additional control on those accesses.

In each case, the {cp10, cp11} controls must be programmed to the same value, otherwise operation is CONSTRAINED UNPREDICTABLE. The ARMv8 CONSTRAINED UNPREDICTABLE behavior is that, for all purposes other than reading the value of the register field, behavior is as if the cp11 field has the same value as the cp10 field. For more information see [Handling of System register control fields for Advanced SIMD and floating-point operation on page K1-5462](#).

For more information about these controls, see:

- [Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-3890](#).
- [General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-3905](#).
- [Enabling Non-secure access to SIMD and floating-point functionality on page G1-3917](#).

Control of accesses to the CPACR from Non-secure PL1 modes

As stated in [General {cp10, cp11} or {TCP10, TCP11} controls](#), the [CPACR](#) controls access to Advanced SIMD and floating-point functionality from PE modes other than Hyp mode. Accesses to the [CPACR](#) from Non-secure PL1 modes can be trapped to EL2, see [Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-3906](#).

Additional controls of Advanced SIMD functionality

- If implemented as an RW field, [CPACR](#).ASEDIS can make all Advanced SIMD instructions UNDEFINED in all modes other than Hyp mode.

- In an implementation that includes EL3, when [CPACR.ASEDIS](#) permits use of the Advanced SIMD instructions or if the [CPACR.ASEDIS](#) control is not implemented, [NSACR.NSASEDIS](#) can make all Advanced SIMD instructions UNDEFINED in Non-secure state.
- In an implementation that includes EL2, when the [CPACR](#) and [NSACR](#) settings permit Non-secure use of the Advanced SIMD instructions, if [HCPTR.TASE](#) is implemented as an RW field it can make these instructions UNDEFINED in Hyp mode, and trap to Hyp mode any use of these instructions in a Non-secure PL0 or PL1 mode.

For more information about these controls, see:

- [Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-3891.](#)
- [Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-3906.](#)
- [Disabling Non-secure access to Advanced SIMD functionality on page G1-3918.](#)

[Pseudocode description of enabling SIMD and floating-point functionality on page G1-3919](#) all of these controls.

FPEXC control of access to Advanced SIMD and floating-point functionality

In addition, [FPEXC.EN](#) is an enable bit for most Advanced SIMD and floating-point operations. When [FPEXC.EN](#) is 0, all Advanced SIMD and floating-point instructions are treated as UNDEFINED except for:

- A VMSR to the [FPEXC](#) or [FPSID](#) register.
- A VMRS from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#) register.

These instructions can be executed only at EL1 or higher.

———— Note —————

- When the [FPSID](#) is accessible, any write access to the [FPSID](#) is ignored.
- When [FPEXC.EN](#) is 0, these operations are treated as UNDEFINED:
 - A VMSR to the [FPSCR](#).
 - A VMRS from the [FPSCR](#).

EL0 access to Advanced SIMD and floating-point functionality

When the access controls summarized in this section permit EL0 access to the Advanced SIMD and floating-point functionality, this applies only to the subset of functionality that is available at EL0. In particular:

- Only Advanced SIMD and Floating-point System register that is accessible is the [FPSCR](#).
- The Advanced SIMD and floating-point instructions are available.

Execution at EL0 corresponds to the application level view of the Advanced SIMD and floating-point functionality, as described in [Advanced SIMD and floating-point System registers on page E1-2302](#).

G1.19.3 Advanced SIMD and floating-point System registers

AArch32 state provides a common set of System registers for the Advanced SIMD and floating-point functionality. This section gives general information about this set of registers, and indicates where each register is described in detail. It contains the following subsections:

- [Register map of the Advanced SIMD and floating-point System registers.](#)
- [Accessing the Advanced SIMD and floating-point System registers on page G1-3883.](#)

Register map of the Advanced SIMD and floating-point System registers

[Table G4-67 on page G4-4212](#) shows the register map of the Advanced SIMD and Floating-point registers. Each register is 32 bits wide. In an implementation that includes EL3, the Advanced SIMD and Floating-point registers are common registers, see [Common System registers on page G4-4160](#).

Accessing the Advanced SIMD and floating-point System registers

Software accesses the Advanced SIMD and floating-point System registers using the VMRS and VMSR instructions, see:

- [VMRS on page F6-3525](#).
- [VMSR on page F6-3528](#).

For example:

```
VMRS <Rt>, FPSID    ; Read Floating-Point System ID Register
VMRS <Rt>, MVFR1    ; Read Media and VFP Feature Register 1
VMSR FPSCR, <Rt>    ; Write Floating-Point System Control Register
```

Software can access the Advanced SIMD and floating-point System registers only if the access controls permit the access, see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

———— Note ————

All hardware ID information can be accessed only from EL1 or higher. This means:

The FPSID is accessible only from EL1 or higher.

This is a change introduced from VFPv3. Previously, the FPSID register can be accessed in all modes.

The MVFR registers are accessible only from EL1 or higher.

Unprivileged software must issue a system call to determine what features are supported.

G1.19.4 Context switching when using Advanced SIMD and floating-point functionality

When the Advanced SIMD and floating-point functionality is used by only a subset of processes, the operating system might implement lazy context switching of the Advanced SIMD and floating-point register file and System registers.

In the simplest lazy context switch implementation, the primary context switch software uses the CPACR.{cp10, cp11} controls to disable access to the Advanced SIMD and floating-point functionality, see [Enabling Advanced SIMD and floating-point support on page G1-3881](#). Subsequently, when a process or thread attempts to use an Advanced SIMD or floating-point instruction, it triggers an Undefined Instruction exception. The operating system responds by saving and restoring the Advanced SIMD and floating-point register file and System registers. Typically, it then re-executes the Advanced SIMD or floating-point instruction that generated the Undefined Instruction exception.

G1.19.5 Floating-point exception traps

Execution of a floating-point instruction can generate an exceptional condition, called a *floating-point exception*.

The ARMv8-A architecture supports synchronous exception generation in the event of any or all of the following floating-point floating-point exceptions:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

———— Note ————

Do not confuse floating-point exceptions with the AArch32 architectural exceptions summarized in [AArch32 state exception descriptions on page G1-3849](#).

Whether an implementation includes synchronous exception generation for these floating-point exceptions is IMPLEMENTATION DEFINED:

- For an implementation that does provide this capability, `FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE}` are the control bits that enable synchronous exception generation for each of the floating-point exceptions.
- For an implementation that does not provide this capability, the `FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE}` are RAZ/WI.

———— **Note** —————

The ARMv8-A architecture does not support asynchronous reporting of floating-point exceptions.

When generating synchronous exceptions for one or more floating-point exceptions is enabled, the synchronous exceptions generated by the floating-point exception traps are taken to the lowest Exception level that can handle such an exception, while adhering to the rule that an exception can never be taken to a lower Exception level. This means that trapped floating-point exceptions taken:

- From EL0 are taken to EL1, except for the following cases when they are taken from Non-secure EL0 to EL2:
 - EL2 is using AArch32 and the value of `HCR.TGE` is 1.
 - EL2 is using AArch64 and the value of `HCR_EL2.TGE` is 1
- From EL1 are taken to EL1.
- From EL2 are taken to EL2.
- From EL3 are taken to EL3.

If the exception is taken to an Exception level that is using AArch64 then it is reported in the `ELR_ELx` for the Exception level to which it is taken, as described in [Exception entry on page D1-1521](#).

If the exception is taken to an Exception level that is using AArch32 then it is taken as an Undefined Instruction exception, see [Undefined Instruction exception on page G1-3849](#). The `FPEXC` identifies the floating-point exceptions that occurred since the corresponding status bits in that register were last set to 0.

See also [Floating-point exceptions on page E1-2303](#).

In an implementation that provides synchronous exception generation for floating-point exceptions:

- Synchronous exception generation applies to floating-point exceptions generated by scalar SIMD and floating-point instructions executed in AArch32 state.
- The registers that are presented to the exception handler are consistent with the state of the PE immediately before the instruction that caused the exception. An implementation is permitted not to restore the cumulative exception flags in the event of such an exception.

ARMv8 does not support the trapping of floating-point exceptions from Advanced SIMD instructions executed in AArch32 state,

The `AArch32.FPTrappedException()` and `FPPProcessException()` pseudocode functions describe the handling of trapped floating-point exceptions generated in AArch32 state.

The `AArch32.FPTrappedException()` and `FPPProcessException()` functions are described in [Chapter J1 ARMv8 Pseudocode](#).

G1.20 Configurable instruction enables and disables, and trap controls

This section describes the controls provided by AArch32 state for enabling, disabling, and trapping particular instructions. Each control is categorized as an *instruction enable*, an *instruction disable*, or a *trap control*:

Instruction enables and instruction disables

Enable or disable the use of one or more particular instructions at a particular Privilege level and Security state.

When an instruction is disabled as a result of an instruction enable or disable, it is UNDEFINED.

The exception generated by attempting to executed an UNDEFINED instruction is:

- Taken to EL1 if the UNDEFINED instruction was executed at EL0, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

When the exception is taken to EL1 it is taken to Undefined mode.

- Otherwise, taken to the Exception level at which the UNDEFINED instruction was executed:
 - If the instruction was executed in Hyp mode the exception is taken to Hyp mode.
 - Otherwise, the exception is taken to Undefined mode.

Trap controls

Control whether one or more instructions, when executed at a particular Privilege level, are *trapped*.

———— Note —————

AArch32 trap controls are described in terms of Privilege levels, rather than Exception levels, because the PL1 traps apply at and are controlled from:

EL1 In Non-secure state, and in Secure state when EL3 is using AArch64.

EL3 In Secure state when EL3 is using AArch32.

For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#).

Trap controls are grouped as:

PL1, excluding Monitor mode

Trapped instructions generate Undefined Instruction exceptions that are taken to Undefined mode, unless the instruction was executed at Non-secure EL0 and is routed to EL2 by the control described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

For more information about these traps see [PL1 configurable controls on page G1-3886](#).

Hyp mode (PL2)

These traps apply only to execution in Non-secure state. This section only describes the traps that apply when EL2 is using AArch32.

Trapped instructions generate:

- Hyp Trap exceptions, taken to Hyp mode, if trapped from a mode other than Hyp mode.
- Undefined Instruction exceptions taken to Hyp mode, if trapped from Hyp mode.

For more information about these traps see [EL2 configurable controls on page G1-3894](#). See also [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

Monitor mode (Secure PL1)

This section only describes the traps that apply when EL3 is using AArch32.

Trapped instructions generate Monitor Trap exceptions, that are taken to Monitor mode.

For more information about these traps see [EL3 configurable controls on page G1-3914](#).

An exception generated as a result of an instruction enable or disable, or a trap control, is only taken if the instruction does not also generate a higher priority exception. [Exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) defines the prioritization of different exceptions on the same instruction.

Exceptions generated as a result of these controls are synchronous exceptions.

For exceptions taken to an Exception level that is using AArch32, only exceptions that are taken to Hyp mode are reported in a syndrome register, the [HSR](#).

———— **Note** —————

- A particular control might have a mnemonic that suggests it is different type of control to the control type it is categorized as. For example, [CPACR.TRCDIS](#) is a trap control even though TRCDIS is a mnemonic for Trace Disable.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.
- [Configurable instruction enables and disables, and trap controls on page D1-1562](#) describes controls provided by AArch64 state for enabling, disabling, and trapping instructions. Generally, where an AArch64 control applies to execution at lower Exception levels, it traps the equivalent functionality when that lower Exception level is using AArch32. See the AArch64 trap controls for more information.

—————
This section is organized as follows:

- [Register access instructions](#).
- [PL1 configurable controls](#).
- [EL2 configurable controls on page G1-3894](#).
- [EL3 configurable controls on page G1-3914](#).
- [Pseudocode description of configurable instruction enables, disables, and traps on page G1-3919](#).

G1.20.1 Register access instructions

When an instruction is disabled or trapped, the exception is taken before execution of the instruction. This means that if the instruction is a register access instruction:

- No access is made before the exception is taken.
- Side-effects that are normally associated with the access do not occur before the exception is taken.

G1.20.2 PL1 configurable controls

In AArch32 state, each control is associated with a particular System register field that is accessible:

- When EL3 is using AArch64, or when an implementation does not include EL3, from EL1.
- When EL3 is using AArch32:
 - In Non-secure state, from EL1.
 - In Secure state, from EL3.

This means that the controls are described as PL1 controls, because PL1 is defined as being the Privilege level of software that is executing:

- At EL3, if the PE is executing in EL3 and EL3 is using AArch32.
- At EL1 under all other conditions.

Where there is an AArch64 control that is equivalent to an AArch32 PL1 control, the AArch64 control is an EL1 control.

Any exception that is generated because of an AArch32 PL1 control is taken to a PL1 mode.

————— **Note** —————

Any exception generated because of an AArch32 PL1 control is taken to AArch32 state.

—————

Table G1-27 shows the AArch32 System registers that contain these controls.

Table G1-27 System registers that contain instruction enables and disables, and trap controls

| Register name | Register description |
|---------------|---|
| SCTLR | System Control Register |
| FPEXC | Floating-point Exception Control Register |
| CPACR | Architectural Feature Access Control Register |
| DBGDSCRExt | Monitor System Debug Control Register |
| PMUSERENR | Performance Monitors User Enable Register |

Table G1-28 summarizes these controls.

Table G1-28 Instruction enables and disables, and trap controls, for exceptions taken to Undefined mode

| Control | Control type ^a | Description |
|--|---------------------------|---|
| SCTLR.{nTWE, nTWI} | T | Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-3888 |
| SCTLR.{SED, ITD} | D | Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-3888 |
| SCTLR.CP15BEN | E | |
| CPACR.TRCDIS | T | Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-3889 |
| CPACR.{cp11, cp10} | E | Enabling use of Advanced SIMD and floating-point functionality on page G1-3890 |
| FPEXC.EN | E | |
| CPACR.ASEDIS | D | |
| DBGDSCRExt.UDCCdis | T | Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers on page G1-3891 |
| CNTKCTL.{PLOPTEN, PLOVTEN, PLOPCTEN, PLOVCTEN} | T | Traps to Undefined mode of EL0 accesses to the Generic Timer registers on page G1-3892 |
| PMUSERENR.{ER, CR, SW, EN} | T | Traps to Undefined mode of EL0 accesses to Performance Monitors registers on page G1-3892 |

a. See Table G1-29.

Table G1-29 Control types, for exceptions taken to Undefined mode

| Abbreviation | Type | See |
|--------------|---------|--|
| D | Disable | Instruction enables and instruction disables on page G1-3885 |
| E | Enable | Instruction enables and instruction disables on page G1-3885 |
| T | Trap | Trap controls on page G1-3885 |

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-3828.

Instructions that fail their condition code check

See [Conditional execution of undefined instructions on page G1-3851](#).

Trapping to PL1 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates an Undefined Instruction exception.

Traps to Undefined mode of EL0 execution of WFE and WFI instructions

SCTLR.{nTWE, nTWI} trap EL0 execution of WFE and WFI instructions to Undefined mode:

SCTLR.nTWE

- 1** This control has no effect on the EL0 execution of WFE instructions.
- 0** Any attempt to execute a WFE instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

SCTLR.nTWI

- 1** This control has no effect on the EL0 execution of WFI instructions.
- 0** Any attempt to execute a WFI instruction at EL0 is trapped to Undefined mode, if the instruction would otherwise have caused the PE to enter a low-power state.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-3872](#).
- [Wait For Interrupt on page G1-3875](#).

Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality

[Table G1-30 on page G1-3889](#) shows the deprecated AArch32 functionality that might have disable controls in the **SCTLR**:

- The SED control is always implemented.
- Whether each of the ITD or CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

When an instruction is disabled by one of these controls, it is UNDEFINED at PL0 and PL1. This means an attempt to execute the instruction at PL0 or PL1 generates an Undefined Instruction exception that is taken to Undefined mode, unless both of the following apply, in which case the attempted execution generates an exception that is taken to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#):

- The instruction is executed at Non-secure EL0 using AArch32.
- Either:
 - EL2 is using AArch32 and the value of **HCR.TGE** is 1.
 - EL2 is using AArch64 and the value of **HCR_EL2.TGE** is 1.

Table G1-30 PL1 controls for disabling and enabling PL0 and PL1 use of AArch32 deprecated functionality

| Deprecated AArch32 functionality | Instruction enable or disable in the SCTLR ^a | Disabled instructions |
|---|--|---|
| SETEND instructions | SED ^b | SETEND instructions |
| Some uses of IT instructions | ITD ^c | See the SCTLR .ITD description |
| Accesses to the CP15DMB , CP15DSB , and CP15ISB barrier instructions | CP15BEN ^d | MCR accesses to the CP15DMB , CP15DSB , and CP15ISB instructions |

- a. The controls that are implemented in **SCTLR** are also implemented in **SCTLR_EL1**, and apply when PL1 is using AArch64 and PL0 is using AArch32.
- b. SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- c. IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- d. System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

———— **Note** —————

The uses of the IT instruction, and use of the **CP15DMB**, **CP15DSB**, and **CP15ISB** barrier instructions, are deprecated for performance reasons.

Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers

If implemented, the **CPACR**.TRCDIS control traps PL0 and PL1 System register accesses to the trace registers to Undefined mode, as follows:

- 1** PL0 and PL1 accesses to the System register interface to the trace macrocell are trapped to Undefined mode
- 0** This control has no effect on PL0 and PL1 accesses to the System register interface to the trace macrocell.

If the **CPACR**.TRCDIS control is not implemented, then the **CPACR**.TRCDIS field is RAZ/WI. This means the **CPACR** does not provide a trap to Undefined mode of PL1 and PL0 System register accesses to trace registers. See the register description for more information.

———— **Note** —————

- System register accesses to the trace macrocell use the (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace System registers are UNDEFINED.
- The ARMv8-A architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see *Register access instructions* on page G1-3886.

If EL3 is implemented and is using AArch32, and **NSACR**.NSTRCDIS is 1, **CPACR**.TRCDIS behaves as RAO/WI in Non-secure state. This behavior also applies if the **CPACR**.TRCDIS control is not implemented.

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-3828.

Enabling use of Advanced SIMD and floating-point functionality

Table G1-31 summarizes the controls of Advanced SIMD and floating-point functionality.

Table G1-31 Controls of use of Advanced SIMD and floating-point functionality

| Control | Type | Description, see |
|--------------------|------|--|
| CPACR.{cp11, cp10} | E | <i>Enabling PL0 and PL1 accesses to the SIMD and floating-point registers</i> |
| FPEXC.EN | E | <i>Enabling access to the SIMD and floating-point registers on page G1-3891</i> |
| CPACR.ASEDIS | D | <i>Disabling PL0 and PL1 execution of Advanced SIMD instructions on page G1-3891</i> |

If any of CPACR.{cp11, cp10}, FPEXC.EN, or for Advanced SIMD instructions, CPACR.ASEDIS, disable a floating-point or an Advanced SIMD instruction, the instruction is UNDEFINED. Support for the CPACR.ASEDIS control is optional, and if the control is not implemented behavior is as if the control permits the execution of Advanced SIMD instructions at PL1 and PL0.

When generated in Non-secure User mode, exceptions generated by these controls can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2 on page G1-3828*.

Enabling PL0 and PL1 accesses to the SIMD and floating-point registers

CPACR.{cp11, cp10} enable PL0 and PL1 accesses to the SIMD and floating-point registers.

When CPACR.cp10 is:

- 00** PL0 and PL1 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- 01** PL0 accesses to Advanced SIMD and floating-point registers or instructions are UNDEFINED.
- 10** Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE.
- 11** This control permits full access to the Advanced SIMD and floating-point functionality from PL0 and PL1.

The value of CPACR.cp11 is ignored. If CPACR.cp11 is programmed with a different value to CPACR.cp10 then CPACR.cp11 is UNKNOWN on a direct read of the CPACR.

———— Note —————

- Software must set CPACR.cp11 and CPACR.cp10 to the same value.

Table G1-32 shows the registers for which accesses are enabled.

Table G1-32 Register accesses enabled at PL0 and PL1 by CPACR.{cp11, cp10}

| Enabled at | Registers |
|---------------------------------------|---|
| PL0 and PL1, or PL0 only ^a | FPSCR, FPEXC, FPSID, MVFR0, MVFR1, MVFR2, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers ^b |

- a. Depending on the value of CPACR.{cp11, cp10}. See the register description for details.
- b. Permitted VMSR accesses to the FPSID are ignored, but for the purposes of the {cp10, cp11} controls the architecture defines a VMSR accesses to the FPSID from EL1 or higher is an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and NSACR.{cp11, cp10} are both set to 0, the functionality described in this section is disabled in Non-secure state, and CPACR.{cp11, cp10} are RAZ/WI in Non-secure state. See *Enabling Non-secure access to SIMD and floating-point functionality on page G1-3917*.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-3880](#).

Enabling access to the SIMD and floating-point registers

FPEXC.EN enables accesses to the SIMD and floating-point registers at all Exception levels, but does not control the following:

- VMSR accesses to the **FPEXC** or **FPSID**.
- VMRS accesses from the **FPEXC**, **FPSID**, **MVFR0**, **MVFR1**, or **MVFR2**.

When **FPEXC.EN** is:

- 1** Accesses to the registers shown in [Table G1-33](#) are enabled at all Exception levels.
- 0** All accesses to the registers shown in [Table G1-33](#) are UNDEFINED.

[Table G1-33](#) shows the registers for which accesses are enabled, and for an exception taken to Hyp mode, how the exception is reported in **HSR**.

Table G1-33 Register accesses enabled when **FPEXC.EN is 1**

| Enabled at | Registers | Syndrome reporting in HSR ^a |
|----------------------|--|--|
| All Exception levels | FPSCR , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. | Exception for an unknown reason, using EC value 0x00 |

- a. Only for exceptions that are taken to Hyp mode.

For more information, see [Advanced SIMD and floating-point support on page G1-3880](#).

Disabling PL0 and PL1 execution of Advanced SIMD instructions

If implemented as an RW field, **CPACR.ASEDIS** can disable PL0 and PL1 execution of Advanced SIMD instructions, as follows:

- 1** Advanced SIMD instructions are UNDEFINED at PL0 and PL1.
- 0** Advanced SIMD instruction execution is enabled at PL0 and PL1.

The instructions that **CPACR.ASEDIS** disables are those described in [Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2306](#).

When the control is not implemented, meaning the **CPACR.ASEDIS** field is RAZ/WI, behavior is as if the control permits execution of Advanced SIMD instructions at PL0 and PL1.

If EL3 is implemented and is using AArch32, and **NSACR.NSASEDIS** is 1, **CPACR.ASEDIS** is RAO/WI in Non-secure state. This also applies when the **CPACR.ASEDIS** control is not implemented.

Traps to Undefined mode of EL0 accesses to the Debug Communications Channel (DCC) registers

DBGDSCRext.UDCCdis traps EL0 accesses to the DCC registers to Undefined mode:

- 1** EL0 accesses to the DCC registers are trapped to Undefined mode
- 0** This control has no effect on EL0 accesses to the DCC registers.

Traps of EL0 accesses to the **DBGDTRRXint** and **DBGDTRTXint** are ignored in Debug state.

[Table G1-34](#) shows the registers for which accesses are trapped.

Table G1-34 Register accesses trapped to Undefined mode when **DBGDSCRext.UDCCdis is 1**

| Traps from | Registers |
|------------|--|
| EL0 | DBGDSCRint , DBGDTRRXint , DBGDTRTXint , DBGDIDR , DBGDSAR , DBGDRAR |

Note

All accesses to these registers are trapped, including LDC and STC accesses to [DBGDTRTXint](#) and [DBGDTRRXint](#), and MRRC accesses to [DBGDSAR](#) and [DBGDRAR](#).

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2](#) on page G1-3828.

Traps to Undefined mode of EL0 accesses to the Generic Timer registers

[CNTKCTL](#).{[PLOPTEN](#), [PLOVTEN](#), [PLOOPCTEN](#), [PLOVCTEN](#)} trap EL0 accesses to the Generic Timer registers to Undefined mode, as follows:

- [CNTKCTL.PLOPTEN](#) traps EL0 accesses to the physical timer registers.
- [CNTKCTL.PLOVTEN](#) traps EL0 accesses to the virtual timer registers.
- [CNTKCTL.PLOOPCTEN](#) traps EL0 accesses to the frequency register and physical counter register.
- [CNTKCTL.PLOVCTEN](#) traps EL0 accesses to the frequency register and virtual counter register.

For all of these controls:

- 1** This control has no effect on EL0 accesses to the corresponding registers.
- 0** EL0 accesses to the corresponding registers are trapped to Undefined mode.

Accesses to the frequency register, [CNTFRQ](#), are only trapped if [CNTKCTL.PLOOPCTEN](#) and [CNTKCTL.PLOVCTEN](#) are both 0.

[Table G1-35](#) shows the registers for which accesses are trapped.

Table G1-35 Register accesses trapped to Undefined mode by [CNTKCTL](#) trap controls

| Traps from | Trap control | Registers |
|------------|---------------------------|--|
| EL0 | PLOPTEN | CNTP_CTL , CNTP_CVAL , CNTP_TVAL |
| | PLOVTEN | CNTV_CTL , CNTV_CVAL , CNTV_TVAL |
| | PLOOPCTEN | CNTFRQ , CNTPCT |
| | PLOVCTEN | CNTFRQ , CNTVCT |

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in [Routing exceptions from Non-secure EL0 to EL2](#) on page G1-3828.

Traps to Undefined mode of EL0 accesses to Performance Monitors registers

[PMUSERENR](#).{[ER](#), [CR](#), [SW](#), [EN](#)} trap EL0 accesses to the Performance Monitors registers to Undefined mode.

For each of these controls:

- 1** This control has no effect on EL0 accesses to the corresponding registers.
- 0** EL0 accesses to the corresponding registers are trapped to Undefined mode.

For those Performance Monitors registers that more than one [PMUSERENR](#).{[ER](#), [CR](#), [SW](#), [EN](#)} control applies to, accesses are only trapped if all controls that apply are set to 0.

The accesses that these trap controls trap might be reads, writes, or both.

Note

- The architecture does not provide traps on Performance Monitors register accesses through the memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, the Performance Monitors registers, including [PMUSERENR](#), are reserved.

Table G1-36 shows the registers for which EL0 accesses are trapped. For each register, the table shows the type of access trapped.

Table G1-36 Register accesses trapped to Undefined mode when disabled from EL0

| Traps from | Trap control | Registers | Access type | |
|------------|--------------|---|-------------|----|
| EL0 | ER | PMXEVCNTR, PMEVCNTR<n> | R | |
| | | PMSELR | RW | |
| | CR | PMCCNTR, accessed using an MRC | R | |
| | CR | PMCCNTR, accessed using an MRRC | R | |
| | SW | PMSWINC | W | |
| | EN | PMCNTENSET, PMCNTENCLR, PMCR, PMOVSr, PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTPER, PMXEVCNTR, PMOVSSET, PMEVCNTR<n>, PMEVTPER<n>, PMCCFILTR | | RW |

When generated in Non-secure User mode, an exception generated by this control can be routed to EL2, as described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-3828.

G1.20.3 EL2 configurable controls

These controls are ignored in Secure state.

Table G1-37 shows the System registers that contain these controls.

Table G1-37 System registers that contain instruction enables and disables, and trap controls

| Register name | Register description |
|---------------|---|
| FPEXC | Floating-point Exception Control Register |
| HCR | Hypervisor Configuration Register |
| HSTR | Hypervisor System Trap Register |
| HCPTR | Hyp Architectural Feature Trap Register |
| HDCR | Hyp Debug Control Register |

Note

- FPEXC.EN is a control that is in a System register provided by PL1. However, it results in exceptions taken to Hyp mode.
- For completeness, Table G1-38 includes the HCR.TGE routing control, that is described in *Routing exceptions from Non-secure EL0 to EL2* on page G1-3828.

Table G1-38 summarizes the controls.

Table G1-38 Instruction enables and disables, and trap controls, for exceptions taken to Hyp mode

| Control | Control type ^a | Description |
|------------------------------|---------------------------|--|
| HSCTLR.{SED, ITD} | D | <i>Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-3897</i> |
| HSCTLR.CP15BEN | E | |
| HCR.{TRVM, TVM} | T | <i>Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-3897</i> |
| HCR.HCD | D | <i>Disabling Non-secure state execution of HVC instructions on page G1-3898</i> |
| HCR.TGE | R | <i>Routing exceptions from Non-secure EL0 to EL2 on page G1-3828</i> |
| HCR.TTLB | T | <i>Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-3898</i> |
| HCR.{TSW, TPC, TPU} | T | <i>Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-3899</i> |
| HCR.TAC | T | <i>Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-3899</i> |
| HCR.TIDCP | T | <i>Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-3900</i> |
| HCR.TSC | T | <i>Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3901</i> |
| HCR.{TID0, TID1, TID2, TID3} | T | <i>Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-3901</i> |

Table G1-38 Instruction enables and disables, and trap controls, for exceptions taken to Hyp mode (continued)

| Control | Control type ^a | Description |
|-----------------------------|---------------------------|--|
| HCR.{TWI, TWE} | T | Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3904 |
| HCPTR.{TCP11, TCP10} | T | General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-3905 |
| FPEXC.EN | T | Enabling access to the SIMD and floating-point registers on page G1-3906 |
| HCPTR.TASE | T | Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality on page G1-3906 |
| HCPTR.TCPAC | T | Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-3906 |

a. See Table G1-39.

Table G1-39 Control types, for exceptions taken to Hyp mode

| Abbreviation | Type | See |
|--------------|-----------------|---|
| D | Disable | Instruction enables and instruction disables on page G1-3885 |
| E | Enable | Instruction enables and instruction disables on page G1-3885 |
| R | Routing control | Routing exceptions from Non-secure EL0 to EL2 on page G1-3828 |
| T | Trap | Trap controls on page G1-3885 |

Also see the following:

- Register access instructions on page G1-3886.
- Instructions that fail their condition code check on page G1-3896.
- Trapping to EL2 of instructions that are UNPREDICTABLE on page G1-3896.

Instructions that fail their condition code check

For UNDEFINED instructions that fail their condition code check, see [Conditional execution of undefined instructions on page G1-3851](#).

For an instruction that has a Hyp trap set, that fails its condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
 - Generates a Hyp Trap exception.
 - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their condition code check. This means that:

- Whenever a Hyp trap is set on an instruction it must either:
 - Always generate a Hyp Trap exception.
 - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of [Conditional execution of undefined instructions on page G1-3851](#) must be consistent with the handling of Hyp traps on instructions that fail their condition code check. [Table G1-40](#) shows this:

Table G1-40 Consistent handling of instructions that fail their condition code check

| Behavior of conditional UNDEFINED instruction ^a | Hyp trap on instruction that fails its condition code check ^b |
|--|--|
| Executes as a NOP | Executes as a NOP |
| Generates an Undefined Instruction exception | Generates a Hyp Trap exception |

- a. As defined in [Conditional execution of undefined instructions on page G1-3851](#). In Non-secure EL0 and EL1 modes, this applies only if no Hyp trap is set for the instruction, otherwise see the behavior in the other column of the table.
- b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

———— **Note** —————

Hyp traps on WFE and WFI instructions generate Hyp Trap exceptions only if the instruction passes its condition code check. See [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3904](#).

Trapping to EL2 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Hyp Trap exception.

———— **Note** —————

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in Non-secure state at EL1 or EL0. This indirectly affects the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a Non-secure EL1 or EL0 mode must not generate a Hyp Trap exception.

Disabling or enabling EL2 use of AArch32 deprecated functionality

Table G1-41 shows the deprecated AArch32 functionality that might have disable controls in the **HSCTLR**:

- The SED control is always implemented.
- Whether each of the ITD, CP15BEN controls is implemented is IMPLEMENTATION DEFINED. If a control is not implemented then the associated functionality cannot be disabled.

These **HSCTLR** controls apply only to execution at EL2 using AArch32. When an instruction is disabled by one of these controls, it is UNDEFINED at EL2, meaning it is undefined in Hyp mode.

Table G1-41 EL2 controls for disabling and enabling EL2 use of AArch32 deprecated functionality

| Deprecated AArch32 functionality | Instruction enable or disable in the HSCTLR | Disabled instructions |
|---|--|--|
| SETEND instructions | SED ^a | SETEND instructions |
| Some uses of IT instructions | ITD ^b | See the HSCTLR.IT description |
| Accesses to the System register (coproc==0b1111) DMB, DSB, and ISB barrier operations | CP15BEN ^c | MCR accesses to the CP15DMB , CP15DSB , and CP15ISB |

- SETEND instruction disable. SETEND instructions are disabled when the value of this field is 1.
- IT instruction disable. If this control is implemented, some uses of IT instructions are disabled when the value of this field is 1.
- System register (coproc==0b1111) memory barrier enable. If this control is implemented, the specified register accesses are disabled when the value of CP15BEN is 0.

———— Note ————

- These controls have no effect on instructions executed in any mode other than Hyp mode. The **SCTLR** provides similar controls that apply to execution in other modes.
- The uses of the IT instruction, and use of the **CP15DMB**, **CP15DSB**, and **CP15ISB** barrier instructions, are deprecated for performance reasons.

Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers

HCR.{TRVM, TVM} trap Non-secure EL1 accesses to the virtual memory control registers to Hyp mode:

HCR.TRVM, for read accesses:

- | | |
|----------|---|
| 1 | Non-secure EL1 reads of the virtual memory control registers are trapped to Hyp mode. |
| 0 | This control has no effect on Non-secure EL1 reads of the virtual memory control registers. |

HCR.TVM, for write access:

- | | |
|----------|--|
| 1 | Non-secure EL1 writes to the virtual memory control registers are trapped to Hyp mode. |
| 0 | This control has no effect on Non-secure EL1 writes to the virtual memory control registers. |

Table G1-42 on page G1-3898 shows the registers for which:

- Reads are trapped to Hyp mode when **HCR.TRVM** is 1.
- Writes are trapped to Hyp mode when **HCR.TVM** is 1.

The table also shows how the exceptions are reported in [HSR](#).

Table G1-42 Register read and write accesses trapped when [HCR](#).{TRVM, TVM} are 1

| Traps from | Registers | Syndrome reporting in HSR |
|----------------|--|--|
| Non-secure EL1 | SCTLR , TTBR0 , TTBR1 , TTBCR , DACR , DFSR , IFSR , DFAR , IFAR , ADFSR , AIFSR , PRRR , NMRR , MAIRO , MAIR1 , AMAIRO , MAIR1 , CONTEXTIDR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |

———— **Note** —————

These registers are not accessible at EL0.

Disabling Non-secure state execution of HVC instructions

[HCR](#).HCD disables Non-secure state execution of HVC instructions:

- 1** HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
- 0** HVC instruction execution is enabled at EL2 and Non-secure EL1.

———— **Note** —————

HVC instructions are always UNDEFINED at EL0.

[HCR](#).HCD is only implemented if EL3 is not implemented. Otherwise, it is RES0. See the [HCR](#) register description.

[Table G1-43](#) shows how the exceptions are reported in [HSR](#).

Table G1-43 Instruction that causes exceptions when [HCR](#).HCD is 1

| Attempted execution in | Disabled instruction | Syndrome reporting in HSR |
|--------------------------|----------------------|--|
| Hyp mode | HVC | Exception for an unknown reason, using EC value 0x00 |
| Mode other than Hyp mode | HVC | Not applicable |

Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions

In the ARMv8-A architecture, the system instruction encoding space includes TLB maintenance instructions.

[HCR](#).TTLB traps Non-secure EL1 execution of TLB maintenance instructions to Hyp mode:

- 1** Any attempt to execute a TLBI instruction at Non-secure EL1 is trapped to Hyp mode.
- 0** This control has no effect on the Non-secure EL1 execution of TLBI instructions.

[Table G1-44](#) shows the instructions that are trapped, and how the exceptions are reported in [HSR](#).

Table G1-44 Instructions trapped to Hyp mode when [HCR](#).TTLB is 1

| Traps from | Trapped instructions | Syndrome reporting in HSR |
|----------------|---|---|
| Non-secure EL1 | TLBIALLIS , TLBIMVAIS , TLBIASIDIS , TLBIMVAAIS , TLBIMVALIS , TLBIMVAALIS , ITLBIALL , ITLBIMVA , ITLBIASID , DTLBIALL , DTLBIMVA , DTLBIASID , TLBIALL , TLBIMVA , TLBIASID , TLBIMVAA , TLBIMVAL , TLBIMVAAL . | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

———— **Note** —————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see [The scope of TLB maintenance instructions on page G4-4101](#).

Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions

[HCR.{TSW, TPC, TPU}](#) trap cache maintenance instructions to Hyp mode:

- 0** The control has no effect on the execution of cache maintenance instructions.
- 1** Any attempt to execute one of the cache maintenance instructions shown in [Table G1-46](#) at Non-secure EL1 is trapped to Hyp mode.

Table G1-45 Controls for trapping cache maintenance instructions to Hyp mode

| Trap control | Trapped instructions |
|-------------------------|---|
| HCR.TSW | Data or unified cache maintenance by set/way |
| HCR.TPC | Data or unified cache maintenance to point of coherency |
| HCR.TPU | Cache maintenance to point of unification |

[Table G1-46](#) shows the instructions that are trapped to Hyp mode, and how the exceptions are reported in [HSR](#).

Table G1-46 Instructions trapped to Hyp mode when [HCR.{TSW, TPC, TPU}](#) are 1

| Traps from | Trap control | Trapped instructions | Syndrome reporting in HSR |
|----------------|--------------|---|--|
| Non-secure EL1 | TSW | DCISW , DCCSW , DCCISW | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x3 |
| | TPC | DCIMVAC , DCCIMVAC , DCCMVAC | |
| | TPU | ICIMVAU , ICIALLU , ICIALLUIS , DCCMVAU | |

———— **Note** —————

These instructions are always UNDEFINED at EL0.

For more information about these instructions, see [Cache maintenance instructions, functional group on page G4-4201](#).

Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register

[HCR.TAC](#) traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode:

- 1** Non-secure EL1 accesses to the Auxiliary Control Registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers.

[Table G1-47](#) shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#):

Table G1-47 Register accesses trapped to Hyp mode when [HCR.TAC](#) is 1

| Traps from | Registers | Syndrome reporting in HSR |
|----------------|---|--|
| Non-secure EL1 | ACTLR and, if implemented, ACTLR2 . | Trapped MCR or MRC access (coproc==0b1111) access, using EC value 0x03 |

———— **Note** ————

The [ACTLR](#) and [ACTLR2](#) are not accessible at EL0.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations

The lockdown, DMA, and TCM features of the ARMv8-A architecture are IMPLEMENTATION DEFINED. The architecture reserves the encodings of a number of System registers for control of these features.

[HCR.TIDCP](#) traps the execution of System register access instructions that access these registers, as follows:

- 1** At Non-secure EL1, any attempt to execute an MCR or MRC instruction with a reserved register encoding shown in [Table G1-48](#) is trapped to Hyp mode.
 At Non-secure EL0, it is IMPLEMENTATION DEFINED whether attempts to execute MCR or MRC instructions with reserved register encodings are:
 - Trapped to Hyp mode.
 - UNDEFINED, and the PE takes the Undefined Instruction exception to Non-secure Undefined mode.
 Any lockdown fault in the memory system caused by the use of these operations in Non-secure state generates a Data Abort exception that is taken to Hyp mode.
- 0** This control has no effect on Non-secure EL0 and EL1 System register access instructions with reserved register encodings shown in [Table G1-48](#).

———— **Note** ————

This means that a Hyp Trap exception taken from Non-secure EL1 to Hyp mode, generated because of a configuration setting in [HCR.TIDCP](#) is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because the register is never accessible at EL1. As [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2.

[Table G1-48](#) shows the register encodings for which accesses are trapped to Hyp mode, and how the exceptions are reported in [HSR](#).

Table G1-48 Encodings trapped to Hyp mode when [HCR.TIDCP](#) is 1

| Traps from | Register encodings | Syndrome reporting in HSR |
|------------------------|--|---|
| Non-secure EL0 and EL1 | An access to any of the following encodings: <ul style="list-style-type: none"> • CRn==c9, opc1=={0-7}, CRm=={c0-c2, c5-c8}, opc2=={0-7}. • CRn==c10, opc1=={0-7}, CRm=={c0, c1, c4, c8}, opc2=={0-7}. • CRn==c11, opc1=={0-7}, CRm=={c0-c8, c15}, opc2=={0-7}. | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

———— **Note** ————

ARM expects the trapping of Non-secure User mode accesses to these functions to Hyp mode to be unusual, and used only when the hypervisor is virtualizing User mode operation. ARM strongly recommends that unless the hypervisor must virtualize User mode operation, a Non-secure User mode access to any of these functions generates an Undefined Instruction exception, as it would if the implementation did not include EL2. The PE then takes this exception to Non-secure Undefined mode.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions

HCR.TSC traps Non-secure EL1 execution of SMC instructions to Hyp mode:

- 1** Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of **SCR.SCD**.
- 0** This control has no effect on Non-secure EL1 execution of SMC instructions.

Table G1-49 shows how the exceptions are reported in **HSR**:

Table G1-49 SMC Instruction trapped to Hyp mode when **HCR.TSC is 1**

| Traps from | Trapped instruction | Syndrome reporting in HSR |
|----------------|-------------------------------------|---|
| Non-secure EL1 | SMC on page F5-2983 | Trapped SMC instruction execution in AArch32 state, using EC value 0x13 |

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

———— **Note** —————

- This trap is implemented only if the implementation includes EL3.
- SMC instructions are always UNDEFINED at EL0.
- **HCR.TSC** traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap and SMC exceptions have different preferred return addresses.

For more information about SMC instructions, see [SMC on page F5-2983](#).

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers

Other than the **MIDR**, **MPIDR**, and **PMCR.N**, the ID registers are divided into groups, with a trap control in the **HCR** for each group.

Table G1-50 ID register groups

| Trap control | Register group |
|-----------------|--|
| HCR.TID0 | <i>ID group 0, Primary device identification registers on page G1-3902</i> |
| HCR.TID1 | <i>ID group 1, Implementation identification registers on page G1-3903</i> |
| HCR.TID2 | <i>ID group 2, Cache identification registers on page G1-3903</i> |
| HCR.TID3 | <i>ID group 3, Detailed feature identification registers on page G1-3904</i> |

These controls trap register accesses from Non-secure EL0 or EL1 to Hyp mode, as follows:

- HCR.TID0**
 - 0** This control has no effect on Non-secure EL1 reads of the ID group 0 registers.
 - 1** Any attempt at Non-secure EL0 or EL1 to read any register in ID group 0 is trapped to Hyp mode
- HCR.TID1**
 - 0** This control has no effect on Non-secure EL1 reads of the ID group 1 registers.
 - 1** Any attempt at Non-secure EL1 to read any register in ID group 1 is trapped to Hyp mode.
- HCR.TID2**
 - 0** This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.

- 1 Any attempt at Non-secure EL0 or EL1 to read any register in ID group 2, and any attempt at Non-secure EL0 or EL1 to write to the **CSSELR**, is trapped to Hyp mode.
- HCR.TID3** 0 This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
- 1 Any attempt at Non-secure EL1 to read any register in ID group 3 is trapped to Hyp mode.

For the **MIDR** and **MPIDR**, and for **PMCR.N**, the architecture provides read/write aliases. The original register becomes accessible only from Hyp mode and Secure state, and a Non-secure EL0 or EL1 read of the original register returns the value of the read/write alias. This substitution is invisible to the EL0 or EL1 software reading the register.

Table G1-51 ID register substitution

| Register | Original | Alias, EL2 using AArch32 |
|---------------------------------------|---------------|--------------------------|
| Main ID | MIDR | VPIDR |
| Multiprocessor Affinity | MPIDR | VMPIDR |
| Performance Monitors Control Register | PMCR.N | HDCR.HPMN |

Reads of the **MIDR**, **MPIDR**, or **PMCR.N** from Hyp mode or Secure state are unchanged by the implementation of EL2, and access the physical registers.

Note

- If the optional Performance Monitors Extension is not implemented, **HDCR.HPMN** is RES0 and **PMCR** is reserved.
- **HDCR.HPMN** also affects whether a Performance Monitors counter can be accessed from Non-secure EL1 or EL0. See the register description of **HDCR** for more information.
- **PMCR** contains other fields that identify the implementation. For more information about trapping accesses to the **PMCR**, see *Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers* on page G1-3912.

A reset into AArch32 state sets **VPIDR** to the **MIDR** value, **VMPIDR** to the **MPIDR** value, and **HDCR.HPMN** to the **PMCR.N** value.

ID group 0, Primary device identification registers

These registers identify some top-level implementation choices.

Table G1-52 shows the registers that are in ID group 0 for traps to Hyp mode, and how the exceptions are reported in **HSR**.

Table G1-52 ID group 0 registers

| Traps from | Group 0 registers | Syndrome reporting in HSR |
|------------------------|-------------------|---|
| Non-secure EL1 | FPSID | Trapped VMRS access, for ID group traps, using EC value 0x08 |
| Non-secure EL0 and EL1 | JIDR | Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 |

Note

The **FPSID** is not accessible at EL0.

If **HCPTR**.{TCP11, TCP10} traps accesses to SIMD and floating-point functionality, then for a read of **FPSID**, that trap has priority over this trap.

When the [FPSID](#) is accessible, a VMSR FPSID, <Rt> instruction is permitted but is ignored. The execution of this VMSR instruction is not trapped by the ID group 0 trap.

ID group 1, Implementation identification registers

These registers often provide coarse-grained identification mechanisms for implementation-specific features.

[Table G1-53](#) shows the registers that are in ID group 1 for traps to Hyp mode, and how the exceptions are reported in [HSR](#).

Table G1-53 ID group 1 registers

| Traps from | Group 1 registers | Syndrome reporting in HSR |
|----------------|---|---|
| Non-secure EL1 | TCMTR , TLBTR , REVIDR , AIDR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

ID group 2, Cache identification registers

These registers describe and control the cache implementation.

[Table G1-54](#) shows the registers that are in ID group 2 for traps to Hyp mode, and how the exceptions are reported in [HSR](#).

Table G1-54 ID group 2 registers

| Traps from | Group 2 registers | Syndrome reporting in HSR |
|------------------------|---|---|
| Non-secure EL0 and EL1 | CTR , CCSIDR , CLIDR , CSSELR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

ID group 3, Detailed feature identification registers

These registers provide detailed information about the features of the implementation.

———— **Note** ————

These registers are called the CPUID registers. There is no requirement for this trap to apply to those registers that the CPUID Identification Scheme defines as reserved. See *The CPUID identification scheme* on page G4-4195.

Table G1-55 shows the registers that are in ID group 3 for traps to Hyp mode, and how the exceptions are reported in HSR.

Table G1-55 ID group 3 registers

| Traps from | Group 3 registers | Syndrome reporting in HSR |
|----------------|---|---|
| Non-secure EL1 | MVFR0 , MVFR1 , MVFR2 . | Trapped VMRS access for ID group traps, using EC value 0x08 |
| | ID_PFR0 , ID_PFR1 , ID_DFR0 , ID_AFR0 . ID_MMFR0 , ID_MMFR1 , ID_MMFR2 , ID_MMFR3 , and ID_MMFR4 , except that if ID_MMFR4 is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether reads of the register are trapped. ID_ISAR0 , ID_ISAR1 , ID_ISAR2 , ID_ISAR3 , ID_ISAR4 , ID_ISAR5 . Any MRC access to any of the following encodings when coproc==0b1111: • opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0, 1}. • opc1 == 0, CRn == c0, CRm == c3, opc2 == 2. • opc1 == 0, CRn == c0, CRm == c5, opc2 == {4, 5}. It is IMPLEMENTATION DEFINED whether HCR.TID3 traps MRC accesses with coproc==0b1111 to encodings in the following range that are not already mentioned in this table: • CRn == c0, opc1 == 0, CRm == {c2-c7}, opc2 == {0-7}. | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

If [HCPTR](#) traps accesses to SIMD and floating-point functionality, then for reads of [MVFR0](#), [MVFR1](#), and [MVFR2](#), that trap has priority over this trap.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions

[HCR.TWE](#), [HCR.TWI](#) trap Non-secure EL0 and EL1 execution of WFE and WFI instructions to Hyp mode:

[HCR.TWE](#):

- 1** Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** This control has no effect on Non-secure EL0 or EL1 execution of WFE instructions.

[HCR.TWI](#):

- 1** Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** This control has no effect on Non-secure EL0 or EL1 execution of WFI instructions.

Table G1-56 shows how the exceptions are reported in [HSR](#).

Table G1-56 Instructions trapped to Hyp mode when `HCR.{TWE, TWI}` are 1

| Traps from | Trapped instructions | Syndrome reporting in HSR |
|------------------------|----------------------|---|
| Non-secure EL0 and EL1 | WFE WFI | Trapped WFI or WFE instruction, using EC value 0x01 |

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** ————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-3872](#).
- [Wait For Interrupt on page G1-3875](#).

General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers

`HCPTR`.{TCP11, TCP10} trap Non-secure accesses to the SIMD and floating-point registers to Hyp mode:

0b11 All Non-secure accesses to the SIMD and floating-point registers are trapped to Hyp mode. Trapped instructions generate:

- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
- Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.

0b00 This control has no effect on Non-secure accesses to the SIMD and floating-point registers.

———— **Note** ————

Software must set `HCPTR.TCP11` and `HCPTR.TCP10` to the same value.

Table G1-57 shows the registers for which accesses are trapped, and how the exceptions are reported in [HSR](#).

Table G1-57 Register accesses trapped to Hyp mode when `HCPTR`.{TCP11, TCP10} are both 0b11

| Traps from | Registers | Syndrome reporting in HSR |
|------------------|---|--|
| Non-secure state | <code>FPSID</code> , <code>MVFR0</code> , <code>MVFR1</code> , <code>MVFR2</code> , <code>FPSCR</code> , <code>FPEXC</code> , and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers. See Advanced SIMD and floating-point System registers on page G1-3882 . | Trapped access to SIMD and floating-point register, resulting from <code>HCPTR</code> , using EC value 0x07 ^a |

- a. VMSR accesses to the `FPSID` are ignored, but for the purposes of this trap the architecture defines a VMSR access to the `FPSID` from EL1 or higher as an access to a SIMD and floating-point register.

If EL3 is implemented and is using AArch32, and `NSACR`.{cp11, cp10} are both set to 0, then `HCPTR`.{TCP11, TCP10} behave as RAO/WI, regardless of their actual value.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-3880](#).

Enabling access to the SIMD and floating-point registers

FPEXC.EN is an instruction enable that enables access to the SIMD and floating-point registers from all Exception levels, but does not control the following:

- VMSR accesses to the **FPEXC** or **FPSID**.
- VMRS accesses from the **FPEXC**, **FPSID**, **MVFR0**, **MVFR1**, or **MVFR2**.

FPEXC.EN is a PL1 control that also applies at EL2. See *Enabling access to the SIMD and floating-point registers* on page G1-3891.

Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality

If implemented as an RW field, **HCPTR.TASE** can trap Non-secure execution of Advanced SIMD instructions to Hyp mode, as follows. This trap applies only when **HCPTR**.{TCP11, TCP10} are both 0:

- 1** Any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode. Trapped instructions generate:
- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
 - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- 0** This control has no effect on Non-secure execution of Advanced SIMD instructions.

When the control is not implemented, meaning the **HCPTR.TASE** field is RAZ/WI, the **HCPTR** does not provide a trap to Hyp mode of the Non-secure execution of Advanced SIMD instructions, other than the **HCPTR**.{TCP11, TCP10} trap that applies to Non-secure execution of both Advanced SIMD and floating-point instructions.

Table G1-32 on page G1-3890 shows the instructions that are trapped, and how the exceptions are reported in **HSR**.

Table G1-58 Instructions trapped to Hyp mode when **HCPTR.TASE is set to 1**

| Traps from | Instructions | Syndrome reporting in HSR |
|------------------|--|---|
| Non-secure state | All Advanced SIMD instructions that are not also floating-point instructions. For more information see <i>Controls of Advanced SIMD operation that do not apply to floating-point operation</i> on page E1-2306. | Trapped access to SIMD and floating-point register, resulting from HCPTR , using EC value 0x07 |

If EL3 is implemented and is using AArch32, and **NSACR.NSASEDIS** is 1, then **HCPTR.TASE** behaves as RAO/WI, regardless of its actual value. This behavior also applies when the **HCPTR.TASE** control is not implemented.

Traps to Hyp mode of Non-secure EL1 accesses to the CPACR

HCPTR.TCPAC traps Non-secure EL1 accesses to the **CPACR** to Hyp mode:

- 1** Non-secure EL1 accesses to the **CPACR** are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL1 accesses to the **CPACR**.

Table G1-59 shows how the exceptions are reported in **HSR**:

Table G1-59 Register accesses trapped to Hyp mode when **HCPTR.TCPAC is 1**

| Traps from | Register | Syndrome reporting in HSR |
|----------------|--------------|---|
| Non-secure EL1 | CPACR | Trapped MCR or MRC access to System register with coproc==0b1111, using EC value 0x03 |

———— **Note** —————

- The **CPACR** is not accessible at EL0.
- In ARMv7 and earlier versions of the ARM architecture, one use of the **CPACR** is to identify what coprocessor, or conceptual coprocessor, functionality is implemented. Legacy software might use this identification mechanism. A hypervisor can use this trap to emulate this mechanism. See [Background to the System register interface on page G1-3879](#) for more information about this functionality.

Traps to Hyp mode of Non-secure System register accesses to trace registers

If implemented, the **HCPTR.TTA** control traps System register accesses to the trace registers from Non-secure state to Hyp mode, as follows:

- 1** Non-secure System register accesses to the trace registers are trapped to Hyp mode. Trapped instructions generate:
- Hyp Trap exceptions, if the exception is taken from Non-secure EL0 or EL1.
 - Undefined Instruction exceptions taken to Hyp mode, if the exception is taken from EL2.
- 0** This control has no effect on Non-secure System register accesses to the trace registers.

If the **HCPTR.TTA** control is not implemented, then **HCPTR.TTA** is RAO/WI. See the register description for more information.

———— **Note** —————

- System register accesses to the trace registers use the System register (coproc==0b1110) encoding space.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED. A resulting Undefined Instruction exception is higher priority than an **HCPTR.TTA** Hyp Trap exception.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see [Register access instructions on page G1-3886](#).

[Table G1-60](#) shows the registers for which accesses are trapped to Hyp mode when **HCPTR.TTA** is 1, and how the exceptions are reported in [HSR](#).

Table G1-60 Register accesses trapped to Hyp mode when **HCPTR.TTA is 1**

| Traps from | Registers | Syndrome reporting in HSR |
|------------------|---|--|
| Non-secure state | System register accesses to all implemented trace registers | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. • MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x0C. |

If EL3 is implemented and is using AArch32, and **NSACR.NSTRCDIS** is 1, then **HCPTR.TTA** behaves as RAO/WI, regardless of its actual value. This behavior applies, also, when the **HCPTR.TTA** control is not implemented.

General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space

HSTR.{T0-T3, T5-T13, T15} trap Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, or MRRC instructions, to the System registers in the (coproc==0b1111) encoding space, by:

- The value of the CRn argument to the instruction, for MCR and MRC instructions.
- The value of the CRm argument to the instruction, for MCRR and MRRC instructions.

This applies for the set of CRn, or CRm, values {c0-c3, c5-c13, c15}.

When an **HSTR**.Tn trap control is:

- 1** Non-secure EL1 accesses to the corresponding System registers in the (coproc==0b1111) encoding space are trapped to Hyp mode.
EL0 accesses to the corresponding System registers are trapped to Hyp mode if they would not be UNDEFINED if the bit was zero.
- 0** This control has no effect on Non-secure EL0 or EL1 accesses to System registers.

———— **Note** —————

This means that a Hyp Trap exception taken from EL1 to EL2, generated because of a configuration setting in **HSTR**.Tn, is a higher priority exception than an Undefined Instruction exception generated because either the System register encoding is unallocated or because a register is never accessible at Non-secure EL1. As *Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816* shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to EL2. This prioritization includes any access from Non-secure EL1 to a register that is only accessible in Secure state. So, for example, an access to the **SCR** from Non-secure EL1:

- When the value of **HSTR**.T1 is 0, generates an Undefined Instruction exception.
- When the value of **HSTR**.T1 is 1, generates a Hyp Trap exception.

Table G1-61 shows the accesses that are trapped, and how the exceptions are reported in **HSR**.

Table G1-61 Accesses trapped to Hyp mode when an **HSTR**.Tn trap is enabled

| Traps from | Trap control | Trapped accesses | Syndrome reporting in HSR |
|-------------------------------------|--------------|--|---|
| Non-secure EL0 and EL1 ^a | Tn | MCR and MRC instructions, with coproc set to 0b1111 and CRn set to n | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |
| | | MCRR and MRRC instructions, with coproc set to 0b1111 and CRm set to n | Trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |

a. As described in this section, traps from EL1 apply whenever the value of **HSTR**.Tn is 1. Traps from EL0 apply only if the value of **HSTR**.Tn is 1 and the access would not be UNDEFINED if the value of **HSTR**.Tn was 0.

For example, when **HSTR**.T7 is 1, considering only accesses from Non-secure EL1:

- Any 32-bit access from a Non-secure PL1 mode using an MRC or MCR instruction with coproc set to 0b1111 and CRn set to c7, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure PL1 mode using an MRRC or MCRR instructions with coproc set to 0b1111 and CRm set to c7, is trapped to Hyp mode.

———— **Note** —————

- Bits[4,14] of the **HSTR** are reserved, RES0. Although the Generic Timer control registers are implemented in the coproc == 0b1111 encoding space with CRn==c14 for an MRC or MCR access, EL2 does not provide a trap on accesses to the Generic Timer System registers.
- An implementation might provide additional controls, in IMPLEMENTATION DEFINED registers, to provide finer-grained control of control of trapping of IMPLEMENTATION DEFINED features.

System registers in the (coproc==0b1111) encoding space with IMPLEMENTATION DEFINED access permission from ELO

For a System register in the (coproc==0b1111) encoding space, that is accessed using a CRn or CRm value that can be trapped by a **HSTR.Tn** control, if an access to the register from User mode is UNDEFINED when the value of the corresponding **HSTR.Tn** trap control is 0, then when that **HSTR.Tn** trap control is 1, it is IMPLEMENTATION DEFINED whether an access from Non-secure User mode generates:

- A Hyp Trap exception.
- An Undefined Instruction exception taken to Non-secure Undefined mode.

———— **Note** —————

ARM expects that trapping to Hyp mode of Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space will be unusual, and used only when the hypervisor must virtualize User mode operation. ARM recommends that, whenever possible, Non-secure User mode accesses to System register in the (coproc==0b1111) encoding space behave as they would if the processor did not implement EL2, generating an Undefined Instruction exception taken to Non-secure Undefined mode if the architecture does not support the User mode access.

Traps to Hyp mode of Non-secure System register accesses to debug registers

HDCR.{TDRA, TDOSA, TDA} trap Non-secure System register accesses to debug registers to Hyp mode, as follows:

- **HDCR**.{TDRA, TDA} trap Non-secure EL0 and EL1 accesses.
- **HDCR**.TDOSA traps Non-secure EL1 accesses.

———— **Note** —————

EL2 does not provide traps of debug register accesses through the optional memory-mapped external debug interface.

System register accesses to the debug registers can have side-effects. When a System register access is trapped to Hyp mode, no side-effects occur before the exception is taken to Hyp mode. See [Register access instructions on page G1-3886](#).

[Table G1-62](#) shows the subsections that list the accesses trapped. The subsections describe how the traps are reported in [HSR](#).

Table G1-62 Traps of Non-secure EL0 and EL1 accesses to debug registers

| Trap control | Subsection |
|----------------------------|---|
| HDCR.TDRA | Trapping Non-secure System register accesses to Debug ROM registers on page G1-3910 |
| HDCR.TDOSA | Trapping Non-secure System register accesses to powerdown debug registers on page G1-3910 |
| HDCR.TDA | Trapping general Non-secure System register accesses to debug registers on page G1-3911 |

———— **Note** —————

System register accesses to debug registers use the (coproc==0b1110) encoding space.

Trapping Non-secure System register accesses to Debug ROM registers

HDCR.TDRA traps Non-secure EL0 and EL1 System register accesses to the Debug ROM registers to Hyp mode:

- 1** Non-secure EL0 or EL1 System register accesses to the Debug ROM registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL0 and EL1 System register accesses to the Debug ROM registers.

[Table G1-63](#) shows the register accesses that are trapped, and how the exceptions are reported in [HSR](#):

Table G1-63 Register accesses trapped to Hyp mode when **HDCR.TDRA is 1**

| Traps from | Registers | Syndrome reporting in HSR |
|------------------------|---|--|
| Non-secure EL0 and EL1 | DBGDRAR , DBGDSAR | For accesses using: <ul style="list-style-type: none"> • MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05. • MRRC instructions, trapped MRRC access (coproc==0b1110), using EC value 0x0C. |

If **HDCR.TDE** or **HCR.TGE** is 1, behavior is as if **HDCR.TDRA** is 1 other than for the purpose of a direct read.

Trapping Non-secure System register accesses to powerdown debug registers

HDCR.TDOSA traps Non-secure EL1 System register accesses to the powerdown debug registers to Hyp mode:

- 1** Non-secure EL1 System register accesses to the powerdown debug registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL1 System register accesses to the powerdown debug registers.

[Table G1-64](#) shows the register accesses that are trapped, and how the exceptions are reported in [HSR](#).

Table G1-64 Register accesses trapped to Hyp mode when **HDCR.TDOSA is 1**

| Traps from | Registers | Syndrome reporting in HSR |
|----------------|---|---|
| Non-secure EL1 | DBGOSLSR , DBGOSLAR , DBGOSDLR , DBGPRCR Any IMPLEMENTATION DEFINED integration registers. Any IMPLEMENTATION DEFINED register with similar functionality that the implementation specifies as trapped by HDCR.TDOSA . | Trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 |

———— **Note** —————

These registers are not accessible at EL0.

If **HDCR.TDE** or **HCR.TGE** is 1, behavior is as if **HDCR.TDOSA** is 1 other than for the purpose of a direct read.

Trapping general Non-secure System register accesses to debug registers

HDCR.TDA traps Non-secure EL0 and EL1 System register accesses to the debug registers that are not mentioned in either of the following:

- [Traps to Hyp mode of Non-secure System register accesses to debug registers on page G1-3909.](#)
- [Trapping Non-secure System register accesses to powerdown debug registers on page G1-3910.](#)

This means that HDCR.TDA traps to Hyp mode Non-secure EL0 and EL1 System register accesses to all debug registers except the following:

- Non-secure System register accesses to [DBGDRAR](#) or [DBGDSAR](#). The [HDCR.TDRA](#) trap traps these accesses.
- Non-secure System register access to [DBGOSLSR](#), [DBGOSLAR](#), [DBGOSDLR](#), or [DBGPRCR](#). The [HDCR.TDOSA](#) trap traps these accesses.

HDCR.TDA does not trap accesses to [DBGDTRXint](#) or [DBGDTRRXint](#) when the PE is in Debug state.

When HDCR.TDA is:

- 1** Non-secure EL0 or EL1 System register accesses to any of the registers shown in [Table G1-65](#) are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL0 or EL1 System register accesses.

[Table G1-65](#) shows how the exceptions are reported in [HSR](#).

Table G1-65 Accesses trapped to Hyp mode when [HDCR.TDA](#) is **1**

| Traps from | Trapped accesses | Syndrome reporting in HSR |
|------------------------|--|---|
| Non-secure EL0 and EL1 | Accesses to the DBGDIDR , DBGDSCRint , DBGDCCINT , DBGDTRRXint , DBGDTRTXint , DBGWFAR , DBGVCR , DBGDSCRext , DBGDTRTXext , DBGDTRRXext , DBGBVR<n> , DBGBCR<n> , DBGBXVR<n> , DBGWCR<n> , DBGWVR<n> , DBGCLAIMSET , DBGCLAIMCLR , DBGAUTHSTATUS , DBGDEVID , DBGDEVID1 , DBGDEVID2 , and DBGOSECRR | For accesses using MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1110), using EC value 0x05 |
| | STC accesses to DBGDTRRXint . LDC accesses to DBGDTRTXint . | Trapped LDC or STC access, using EC value 0x06 |

If [HDCR.TDE](#) or [HCR.TGE](#) is 1, behavior is as if [HDCR.TDA](#) is 1 other than for the purpose of a direct read.

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the Generic Timer registers

[CNTHCTL](#).{[PL1PCEN](#), [PL1PCTEN](#)} trap Non-secure EL0 and EL1 accesses to the Generic Timer registers to Hyp mode, as follows:

- [CNTHCTL](#).[PL1PCEN](#) traps Non-secure EL0 and EL1 accesses to the physical timer registers.
- [CNTHCTL](#).[PL1PCTEN](#) traps Non-secure EL0 and EL1 accesses to the physical counter register.

For each of these controls:

- 1** This control has no effect on Non-secure EL0 and EL1 accesses to the registers shown in [Table G1-66 on page G1-3912](#).
- 0** Non-secure EL0 and EL1 accesses are trapped to Hyp mode.

Table G1-66 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-66 Register accesses trapped to Hyp mode by CNTHCTL trap controls

| Traps from | Trap control | Registers | Syndrome reporting in HSR |
|------------------------|--------------|--------------------------------|--|
| Non-secure EL0 and EL1 | PL1PCEN | CNTP_CTL, CNTP_CVAL, CNTP_TVAL | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 MCRR or MRRC instructions, trapped MCRR or MRRC access (coproc==0b1111), using EC value 0x04 |
| | PL1PCTEN | CNTPCT | Trapped MCRR or MRRC access (coproc==0b1110), using EC value 0x04 |

Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers

If the Performance Monitors Extension is implemented, HDCR.{TPM, TPMCR} trap Non-secure EL0 and EL1 accesses to the Performance Monitors registers to Hyp mode:

HDCR.TPM:

- 1** Non-secure EL0 and EL1 accesses to all Performance Monitors registers are trapped to Hyp mode.
- 0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors registers.

HDCR.TPMCR:

- 1** Non-secure EL0 and EL1 accesses to the Performance Monitors Control Register are trapped to Hyp mode.

———— **Note** —————

The conditions for this trap are identical to those for the trap controlled by HDCR.TPM

- 0** This control has no effect on Non-secure EL0 and EL1 accesses to the Performance Monitors Control Registers.

———— **Note** —————

- EL2 does not provide traps on Performance Monitor register accesses through the optional memory-mapped external debug interface.
- If the Performance Monitors Extension is not implemented, HDCR.{TPM, TPMCR} are RES0.

Table G1-67 shows the registers for which accesses are trapped, and how the exceptions are reported in HSR.

Table G1-67 Register accesses trapped to Hyp mode when HDCR.{TPM, TPMCR} are 1

| Traps from | Trap control | Registers | Syndrome reporting in HSR |
|---------------------------|--------------|---|--|
| Non-secure EL0 and EL1 | TPM | PMCR, PMCNTENSET, PMCNTENCLR, PMOVS _R , PMSWINC, PMSELR, PMCEID0, PMCEID1, PMCCNTR, PMXEVTYPER, PMXEVCNTR, PMUSERENR, PMINTENSET, PMINTENCLR, PMOVSSET, PMEVCNTR<n>, PMEVTYPER<n>, PMCCFILTR | For accesses using: <ul style="list-style-type: none"> MCR or MRC instructions, trapped MCR or MRC access (coproc==0b1111), using EC value 0x03. MCR or MRRC instructions, trapped MCR or MRRC access (coproc==0b1111), using EC value 0x04. |
| | TPMCR | PMCR | Trapped MCR or MRC access (coproc==0b1111), using EC value 0x03 |

———— **Note** —————

HDCR.HPMN affects whether a counter can be accessed from Non-secure EL1 or EL0. See the register description of HDCR for more information.

G1.20.4 EL3 configurable controls

Table G1-68 shows the System registers that contain these controls.

Table G1-68 System registers that contain instruction enables and disables, and trap controls

| Register name | Register description |
|---------------|------------------------------------|
| SCR | Secure Configuration Register |
| NSACR | Non-secure Access Control Register |

Table G1-69 summarizes the controls.

Table G1-69 EL3 Instruction enables and disables, and trap controls

| Control | Type of control ^a | Trap |
|--------------------|------------------------------|---|
| SCR.{TWE, TWI} | T | Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-3915 |
| SCR.HCE | E | Enabling EL2 and Non-secure EL1 execution of HVC instructions on page G1-3916 |
| SCR.SCD | D | Disabling SMC instructions on page G1-3916 |
| NSACR.NSTRCDIS | D | Disabling Non-secure System register access to the trace registers on page G1-3917 |
| NSACR.{cp11, cp10} | E | Enabling Non-secure access to SIMD and floating-point functionality on page G1-3917 |
| NSACR.NSASEDIS | D | Disabling Non-secure access to Advanced SIMD functionality on page G1-3918 |

a. See Table G1-70.

Table G1-70 Control types, for AArch32 EL3 controls

| Abbreviation | Type | See |
|--------------|---------|--|
| D | Disable | Instruction enables and instruction disables on page G1-3885 |
| E | Enable | Instruction enables and instruction disables on page G1-3885 |
| T | Trap | Trap controls on page G1-3885 |

Also see the following:

- [Register access instructions on page G1-3886.](#)
- [Instructions that fail their condition code check.](#)
- [Trapping to EL3 of instructions that are UNPREDICTABLE on page G1-3915.](#)

Instructions that fail their condition code check

For UNDEFINED instructions that fail their condition code check, see [Conditional execution of undefined instructions on page G1-3851.](#)

For an instruction that has a Monitor trap set, that fails its condition code check:

- Unless the trap description states otherwise, it is IMPLEMENTATION DEFINED whether the instruction:
 - Generates a Monitor Trap exception.
 - Executes as a NOP.

Any implementation must be consistent in its handling of instructions that fail their condition code check. This means that:

- Whenever a Monitor trap is set on such an instruction it must either:
 - Always generate a Monitor trap exception.
 - Always treat the instruction as a NOP.
- The IMPLEMENTATION DEFINED part of the requirements of *Conditional execution of undefined instructions* on page G1-3851 must be consistent with the handling of Monitor traps on instructions that fail their condition code check. Table G1-71 shows this:

Table G1-71 Consistent handling of instructions that fail their condition code check

| Behavior of conditional UNDEFINED instruction ^a | Monitor trap on instruction that fails its condition code check ^b |
|--|--|
| Executes as a NOP | Executes as a NOP |
| Generates an Undefined Instruction exception | Generates a Monitor trap exception |

- a. As defined in *Conditional execution of undefined instructions* on page G1-3851. In Non-secure EL0 and EL1 modes, this applies only if no Monitor trap is set for the instruction, otherwise see the behavior in the other column of the table.
- b. For a trapped instruction executed in a Non-secure EL1 or EL0 mode.

———— **Note** ————

When SCR{TWE, TWI} is set so that conditional WFE and WFI instructions are trapped to Monitor mode, the attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check. See *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode*.

Trapping to EL3 of instructions that are UNPREDICTABLE

For an instruction that is UNPREDICTABLE, when the instruction is disabled or trapped then it is CONSTRAINED UNPREDICTABLE whether execution of the instruction generates a Monitor Trap exception.

———— **Note** ————

UNPREDICTABLE and CONSTRAINED UNPREDICTABLE behavior must not perform any function that cannot be performed at the current or lower Exception level using instructions that are not UNPREDICTABLE and are not CONSTRAINED UNPREDICTABLE. This means that disabling or trapping an instruction changes the set of instructions that might be executed in modes other than Monitor mode. This affects, indirectly, the permitted behavior of UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions.

If no instructions are trapped, the attempted execution of an UNPREDICTABLE instruction in a mode other than Monitor mode must not generate a Monitor Trap exception.

Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode

SCR{TWE, TWI} trap WFE and WFI instructions to Monitor mode:

- | | | |
|----------------|----------|--|
| SCR.TWE | 1 | Any attempt to execute a WFE instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state. |
| | 0 | This control has no effect on the execution of WFE instructions. |

- SCR.TWI** **1** Any attempt to execute a WFI instruction in any mode other than Monitor mode is trapped to Monitor mode, if the instruction would otherwise have caused the PE to enter a low-power state.
- 0** This control has no effect on the execution of WFI instructions.

For PL0 and PL1, these traps apply to WFE and WFI instruction execution in both Security states.

The attempted execution of a conditional WFE or WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** —————

Since a WFE or WFI can complete at any time, even without a Wakeup event, the traps on WFE or WFI are not guaranteed to be taken, even if the WFE or WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

For more information about these instructions, and when they can cause the PE to enter a low-power state, see:

- [Wait For Event and Send Event on page G1-3872.](#)
- [Wait For Interrupt on page G1-3875.](#)

Enabling EL2 and Non-secure EL1 execution of HVC instructions

SCR.HCE enables EL2 and Non-secure EL1 execution of HVC instructions:

- 1** HVC instruction execution is enabled at EL2 and Non-secure EL1.
- 0** HVC instructions are:
- UNDEFINED at Non-secure EL1. The Undefined Instruction exception is taken to Undefined mode.
 - CONSTRAINED UNPREDICTABLE at EL2. The behavior must be one of the following:
 - The instruction is UNDEFINED.
 - The instruction executes as a NOP.

———— **Note** —————

- If EL2 is not implemented, **SCR.HCE** is RES0 and HVC is UNDEFINED.
- HVC instructions are always UNDEFINED at EL0 and in Secure state.

Disabling SMC instructions

SCR.SCD disables SMC instructions:

- 1** **In Non-secure state**
- SMC instructions are UNDEFINED. The Undefined Instruction exception is taken from the current Exception level to the current Exception level.
- In Secure state**
- Behavior is one of the following:
- The instruction is UNDEFINED.
 - The instruction executes as a NOP.
- 0** SMC instructions are enabled.

———— **Note** —————

- SMC instructions are always UNDEFINED at EL0.

- When the value of `HCR.TSC` is 1, any attempted execution of an SMC instruction at Non-secure EL1 is trapped to EL2, regardless of the value of `SCR.SCD`, see [Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3901](#). As [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) shows, this is an exception to the general exception prioritization rules, that prioritize most Undefined Instruction exceptions taken to Undefined mode above traps to a higher Exception level.

Disabling Non-secure System register access to the trace registers

`NSACR.NSTRCDIS` disables Non-secure System register accesses to the trace registers, from all Privilege levels:

- 1** Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
- `CPACR.TRCDIS` behaves as RAO/WI, regardless of its actual value. See [Traps to Undefined mode of PL0 and PL1 System register accesses to trace registers on page G1-3889](#). This behavior applies even if the `CPACR.TRCDIS` control is not implemented. See the referenced section for more information.
 - `HCPTR.TTA` behaves as RAO/WI, regardless of its actual value. See [Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-3907](#).
- 0** There is no effect on accesses to `CPACR.TRCDIS` and `HCPTR.TTA`.

Note

- System register accesses to the trace registers use the (coproc==0b1111) encoding space.
- `NSACR.NSTRCDIS` might be implemented as RAZ/WI. See the `NSACR` register description for more information.
- The ETMv4 architecture does not permit EL0 to access the trace registers. If the ARMv8-A architecture is implemented with an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- EL3 does not provide Non-secure access controls on trace register accesses through the optional memory-mapped external debug interface.

Enabling Non-secure access to SIMD and floating-point functionality

`NSACR.{cp11, cp10}` enable Non-secure access to the SIMD and floating-point registers, from all Privilege levels:

- 0b11** All accesses, from both Security states, are enabled.
- 0b00** Non-secure state accesses are disabled. Secure state accesses are enabled. If the PE is in Non-secure state:
- `CPACR.{cp11, cp10}` behave as RAZ/WI. See [Enabling PL0 and PL1 accesses to the SIMD and floating-point registers on page G1-3890](#).
 - `HCPTR.{TCP11, TCP10}` behave as RAO/WI. See [General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers on page G1-3905](#).

Note

Software must set `NSACR.cp11` and `NSACR.cp10` to the same value.

For more information about SIMD and floating-point support, see [Advanced SIMD and floating-point support on page G1-3880](#).

Disabling Non-secure access to Advanced SIMD functionality

[NSACR.NSASEDIS](#) disables Non-secure accesses to the Advanced SIMD functionality, from all Privilege levels:

- 1** Non-secure state accesses are disabled. Secure accesses are enabled. If the PE is in Non-secure state:
- [CPACR.ASEDIS](#) behaves as RAO/WI. See *Disabling PL0 and PL1 execution of Advanced SIMD instructions* on page G1-3891.
 - [HCPTR.TASE](#) behaves as RAO/WI. See *Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality* on page G1-3906.
- These behaviors apply even if one or both of the [CPACR.ASEDIS](#) and [HCPTR.TASE](#) controls is not implemented. See the referenced sections for more information.
- 0** There is no effect on [CPACR.ASEDIS](#) and [HCPTR.TASE](#).

G1.20.5 Pseudocode description of configurable instruction enables, disables, and traps

The pseudocode function `AArch32.CheckITEnabled()` checks whether the T32 IT instruction is enabled.

The pseudocode function `AArch32.CheckSETENDEnabled()` checks whether the SETEND instruction is disabled.

The pseudocode function for `AArch32.CheckForSMCTrap()` checks for traps on an SMC instruction.

The `AArch32.CheckForWfXTrap()` pseudocode function checks for traps on WFE and WFI instructions:

Pseudocode description of enabling SIMD and floating-point functionality

The `AArch32.CheckAdvSIMDorFPEEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` pseudocode functions take appropriate action if an SIMD or floating-point instruction is used when the SIMD and floating-point functionality is not enabled or is trapped.

The `CheckAdvSIMDorVFPEEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEEnabled()` wrapper functions support the `AArch32.CheckAdvSIMDorFPEEnabled()` and `AArch32.CheckFPAdvSIMDTrap()` functions.

The `AArch32.CheckAdvSIMDorFPEEnabled()`, `AArch32.CheckFPAdvSIMDTrap()`, `CheckAdvSIMDorVFPEEnabled()`, `CheckAdvSIMDEnabled()`, and `CheckVFPEEnabled()` functions are described in [Chapter J1 ARMv8 Pseudocode](#).

Chapter G2

AArch32 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch32 self-hosted debug exception model. It is organized as follows:

Introductory information

- [About self-hosted debug on page G2-3922.](#)
- [The debug exception enable controls on page G2-3926.](#)

The debug Exception model

- [Routing debug exceptions on page G2-3927.](#)
- [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929.](#)
- [The effect of powerdown on debug exceptions on page G2-3931.](#)
- [Summary of permitted routing and enabling of debug exceptions on page G2-3932.](#)
- [Pseudocode description of debug exceptions on page G2-3934.](#)

The debug exceptions

- [Breakpoint Instruction exceptions on page G2-3935.](#)
- [Breakpoint exceptions on page G2-3938.](#)
- [Watchpoint exceptions on page G2-3961.](#)
- [Vector Catch exceptions on page G2-3975.](#)

Synchronization requirements

The behavior of self-hosted debug after changes to System registers, or after changes to the authentication interface, but before a *Context synchronization event* guarantees the effects of the changes:

- [Synchronization and debug exceptions on page G2-3983.](#)

G2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, that are taken using the exception model described in:

- [Chapter D1 The AArch64 System Level Programmers' Model](#), if the exception is taken to AArch64 state.
- [Chapter G1 The AArch32 System Level Programmers' Model](#), if the exception is taken to AArch32 state.

This section introduces some terms used in describing self-hosted debug, and then introduces the debug exceptions. See:

- [Definition of a debugger in the context of self-hosted debug](#).
- [Context ID and Process ID](#).

G2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

G2.1.2 Context ID and Process ID

In AArch32 state, the [CONTEXTIDR](#) identifies the current *Context ID*, that is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

When using the Long-descriptor translation table format, the [CONTEXTIDR](#) has a single field, PROCID, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical when using this translation table format.

When using the Short-descriptor translation table format:

- [CONTEXTIDR](#)[31:0] defines the Context ID, that is used for breakpoint and watchpoint matching.
- [CONTEXTIDR](#)[31:8] defines the Process ID.
- [CONTEXTIDR](#)[7:0] define the ASID. See [Global and process-specific translation table entries on page G4-4089](#). This means that, when using the Short-descriptor translation table format, the ASID is always bits[7:0] of the Context ID.

G2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions. The debug exceptions that can be generated in an AArch32 stage 1 translation regime are:

- [Breakpoint Instruction exceptions on page G2-3923](#).
- [Breakpoint exceptions on page G2-3923](#), generated by hardware breakpoints.
- [Watchpoint exceptions on page G2-3924](#), generated by hardware watchpoints.
- [Vector Catch exceptions on page G2-3924](#).

———— **Note** —————

In addition, *Software Step exceptions* can be generated in stage 1 of an AArch32 translation regime. However, these are always taken to AArch64 state. [Software Step exceptions on page D2-1628](#) describes this.

The PE can only generate a particular debug exception when both:

1. Debug exceptions are enabled from the current Exception level and Security state.

See [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929](#). Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

2. A debugger has enabled that particular debug exception.

All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the [DBGDSCRExt](#). See [The debug exception enable controls on page G2-3926](#).

———— **Note** —————

If *halting is allowed* and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.

For the definition of halting is allowed, see [Halting allowed and halting prohibited on page H2-4845](#).

When a debug exception is taken to an Exception level that is using AArch32:

- If the debug exception is a Watchpoint exception, it is taken as a Data Abort exception.
- Otherwise, it is taken as a Prefetch Abort exception.

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A32 and T32 instruction sets is `BKPT #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

PE behavior

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Privilege level and AArch32 mode.
- The current Security state.

For more information, see [Breakpoint Instruction exceptions on page G2-3935](#).

Breakpoint exceptions

The ARMv8-A architecture provides 2-16 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on particular instruction addresses, or based on particular PE contexts, or both.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The ARMv8-A architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch32 translation regime:

- Address:
 - Address Match.
 - Address Mismatch.Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
 - Context ID Match. Matches with the Context ID value held in the [CONTEXTIDR](#).
 - VMID Match. Matches with the VMID value held in the [VTTB](#).
 - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a Context breakpoint, so that the Address breakpoint only generates a Breakpoint exception if the PE is in a particular context when the address match or mismatch occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see [Breakpoint exceptions](#) on page G2-3938.

Watchpoint exceptions

The ARMv8-A architecture provides 2-16 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a *Linked Context* type. In this case, the watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

PE behavior

If halting is allowed and `EDSCR.HDE` is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See [Chapter H2 Debug State](#).

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see [Watchpoint exceptions](#) on page G2-3961.

Vector Catch exceptions

These are used to trap exceptions. The ARMv8-A architecture provides two forms of vector catch, *address-matching* and *exception-trapping*. Only one form can be implemented.

Whichever form is implemented, a debugger must enable Vector Catch exceptions for one or more exception vectors by programming the `DBGVCR`. Generation of Vector Catch exceptions is then as follows:

- For the address-matching form, a Vector Catch exception is generated whenever the virtual address of an instruction matches a vector that Vector Catch exceptions are enabled for.
- For the Exception-trapping form, a Vector Catch exception is generated as part of exception entry for exception types that correspond to vectors that Vector Catch exceptions are enabled for.

PE behavior

If debug exceptions are:

- Enabled, Vector Catch exceptions can be generated.
- Disabled, vector catch is ignored.

For more information, see [Vector Catch exceptions](#) on page G2-3975.

[Table G2-1](#) on page G2-3925 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table G2-1 PE behavior and pseudocode for each of the debug exceptions

| Debug exception | PE behavior if debug exceptions are: | | Pseudocode |
|----------------------------------|---|--------------------------------|---|
| | Enabled | Disabled | |
| Breakpoint Instruction exception | Takes Prefetch Abort exception | Takes Prefetch Abort exception | AArch32.SoftwareBreakpoint() |
| Breakpoint exception | Takes Prefetch Abort exception ^a | Ignored | See <i>Pseudocode description of Breakpoint exceptions taken from AArch32 state</i> on page G2-3959 |
| Watchpoint exception | Takes Data Abort exception ^a | Ignored | See <i>Pseudocode description of Watchpoint exceptions taken from AArch32 state</i> on page G2-3974 |
| Vector Catch exception | Takes Prefetch Abort exception | Ignored | See <i>Pseudocode description of Vector Catch exceptions</i> on page G2-3981 |

- a. If halting is allowed and [EDSCR.HDE](#) is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See [Chapter H2 Debug State](#).

G2.2 The debug exception enable controls

The enable controls for each debug exception are as follows:

Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

[DBGDSCRExt.MDBGen](#), plus an enable control for each breakpoint, [DBGBCR<n>.E](#).

Watchpoint exceptions

[DBGDSCRExt.MDBGen](#), plus an enable control for each watchpoint, [DBGWCR<n>.E](#).

Vector Catch exceptions

[DBGDSCRExt.MDBGen](#).

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929](#).

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

G2.3 Routing debug exceptions

Debug exceptions are usually routed to Abort mode. However, if EL2 is implemented, the following applies:

- Breakpoint Instruction exceptions taken from Hyp mode are routed to Hyp mode.
All other debug exceptions are disabled from Hyp mode.
- The routing of debug exceptions taken from Non-secure PL1 and PL0 depends on [HDCR.TDE](#):

| | |
|----------|--|
| 1 | Debug exceptions taken from Non-secure PL1 and PL0 are routed to Hyp mode. |
| 0 | Debug exceptions taken from Non-secure PL1 and PL0 are routed to Abort mode. |

———— **Note** ————

If [HCR.TGE](#) is 1, [HDCR.TDE](#) is treated as being 1 except for the purpose of a direct read of [HDCR](#).

[Table G2-2](#) shows this.

Table G2-2 The effect of the TGE and TDE control bits on debug exception routing

| HCR.TGE | HDCR.TDE | Debug exceptions taken from Non-secure PL1 and PL0 are taken to: |
|-------------------------|--------------------------|--|
| 0 | 0 | Non-secure Abort mode |
| 0 | 1 | Hyp mode |
| 1 | X | Hyp mode |

———— **Note** ————

If EL2 is not implemented, the PE behaves as if both [HCR.TGE](#) and [HDCR.TDE](#) are 0.

The following tables show the routing of debug exceptions:

Table G2-3 Routing when both EL3 and EL2 are implemented

| HDCR.TDE ^a | Target AArch32 mode when executing in: | | | Secure state |
|---------------------------------------|--|-----------------------|-----------------------|-------------------|
| | Non-secure: | | | |
| | PL0 | PL1 | PL2 | |
| 0 | Non-secure Abort mode | Non-secure Abort mode | Hyp mode ^b | Secure Abort mode |
| 1 | Hyp mode | Hyp mode | Hyp mode ^b | Secure Abort mode |

- a. If [HCR.TGE](#) is 1, this bit is treated as being 1 other than for a direct read of [HDCR](#).
- b. Only applies to Breakpoint Instruction exceptions. All other debug exceptions are disabled.

Table G2-4 Routing when EL3 is implemented and EL2 is not implemented

| Target AArch32 mode when executing in: | |
|--|-------------------|
| Non-secure state | Secure state |
| Non-secure Abort mode | Secure Abort mode |

Table G2-5 Routing when EL3 is not implemented and EL2 is implemented

| HDCR.TDE^a | Target AArch32 mode when executing in Non-secure: | | |
|-----------------------------|--|-----------------------|-----------------------|
| | PL0 | PL1 | PL2 |
| 0 | Non-secure Abort mode | Non-secure Abort mode | Hyp mode ^b |
| 1 | Hyp mode | Hyp mode | Hyp mode ^b |

- a. If **HCR.TGE** is 1, this bit is treated as being 1 other than for a direct read of **HDCR**.
- b. Only applies to Breakpoint Instruction exceptions. All other debug exceptions are disabled.

G2.3.1 Pseudocode description of routing debug exceptions

`DebugTarget()` returns the current debug target Exception level. `DebugTargetFrom()` returns the debug target Exception level for the specified Security state.

G2.4 Enabling debug exceptions from the current Privilege level and Security state

A debug exception can only be taken if all of the following are true:

- The OS lock is unlocked.
- `DoubleLockStatus() == FALSE`.
- The debug exception is enabled from the current Privilege level.
- The debug exception is enabled from the current Security state.

Table G2-6 shows when debug exceptions are enabled from the current Privilege level.

Table G2-6 Whether debug exceptions are enabled from the current Privilege level

| Current Privilege level | Breakpoint Instruction exceptions | All other debug exceptions |
|-------------------------|-----------------------------------|----------------------------|
| PL2 | Enabled | Disabled |
| PL1 | Enabled | Enabled |
| PL0 | | |

Table G2-7 shows when debug exceptions are enabled from the current Security state.

Table G2-7 Whether debug exceptions are enabled from the current Security state

| Current Security state | Breakpoint Instruction exceptions | All other debug exceptions |
|------------------------|-----------------------------------|---|
| Non-secure | Enabled | Enabled from PL1 and PL0 only. |
| Secure | Enabled | Depends on SDCR.SPD and SDER.SUIDEN . See Disabling debug exceptions from Secure state . |

G2.4.1 Disabling debug exceptions from Secure state

If EL3 is implemented, software executing at EL3 can enable or disable all debug exceptions taken from Secure PL1 other than Breakpoint Instruction exceptions, by using one of:

- The *Secure Privileged Debug* field, [SDCR.SPD](#), if EL3 is using AArch32.
- The *AArch32 Secure Privileged Debug* field, [MDCR_EL3.SPD32](#), if EL3 is using AArch64.

If debug exceptions are disabled from Secure PL1, software executing at Secure PL1 can set the *Secure User Invasive Debug Enable* bit, [SDER.SUIDEN](#), to 1 to enable all debug exceptions taken from Secure PL0 other than Breakpoint Instruction exceptions.

———— **Note** —————

Breakpoint Instruction exceptions are always enabled.

The ARMv8-A architecture does not support disabling debug in Non-secure state.

———— **Note** —————

If the boot software that is executed when reset is deasserted programs SUIDEN and SPD so that all debug exceptions are disabled from Secure state, software operating at EL3 never has to switch any of the debug registers between the Security states.

G2.4.2 Pseudocode description of enabling debug exceptions

[AArch64.GenerateDebugExceptions\(\)](#) determines whether debug exceptions are enabled from the current Exception level and Security state. [AArch64.GenerateDebugExceptionsFrom\(\)](#) determines whether debug exceptions are enabled from the specified Exception level and Security state.

G2.5 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences on page H6-4951 describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

Debug exceptions other than Breakpoint Instruction exceptions are enabled only if both the OS Lock is unlocked and `DoubleLockStatus() == FALSE`.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

G2.6 Summary of permitted routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Privilege level and Security state. [Table G2-8](#) shows the routing of these. In the table, n/a means not applicable.

Table G2-8 Routing of Breakpoint Instruction exceptions

| Current Security state | HDCR.TDE ^a : | Target when enabled from: | | |
|------------------------|-------------------------|--------------------------------|--------------------------------|----------|
| | | PL0 | PL1 | PL2 |
| Secure | X | Secure Abort mode ^b | Secure Abort mode ^b | n/a |
| Non-secure | 0 | Non-secure Abort mode | Non-secure Abort mode | Hyp mode |
| | 1 | Hyp mode | Hyp mode | Hyp mode |

- If EL2 is not implemented, behavior is as if the value of this bit is 0. Otherwise, if the value of [HCR.TGE](#) is 1, [HDCR.TDE](#) is treated as being 1 other than for a direct read of [HDCR](#).
- If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1.

All other debug exceptions

The enabling and permitted routing is controlled by all of the following:

- [SDCR.SPD](#).
- [SDER.SUIDEN](#).
- [HDCR.TDE](#).
- The IMPLEMENTATION DEFINED authentication interface.

[Table G2-9](#) shows the valid combinations of the values of [SDCR.SPD](#), [SDER.SUIDEN](#), [HDCR.TDE](#), and, in the *Auth* column, the input from the IMPLEMENTATION DEFINED authentication interface described by the pseudocode function [AArch32.SelfHostedSecurePrivilegedInvasiveDebugEnabled\(\)](#). For each combination, the table shows where debug exceptions are enabled from and where they are taken to.

In the table, n/a means not applicable and a dash, -, means that debug exceptions are disabled from that Exception level.

Table G2-9 Breakpoint, Watchpoint, and Vector Catch exceptions

| Debug state | Lock ^a | Current Security state | SPD ^b | Auth ^c | SUIDEN | TDE ^d | Target AArch32 mode when enabled from: | | |
|-------------|-------------------|------------------------|------------------|-------------------|--------|------------------|--|--------------------------------|-----|
| | | | | | | | PL0 | PL1 | PL2 |
| Yes | X | X | 0bXX | X | X | X | - | - | - |
| No | TRUE | X | 0bXX | X | X | X | - | - | - |
| No | FALSE | Secure | 0b00 | TRUE | 0 | X | - | - | n/a |
| No | FALSE | Secure | 0b00 | TRUE | 1 | X | Secure Abort mode ^e | - | n/a |
| No | FALSE | Secure | 0b00 | FALSE | X | X | Secure Abort mode ^e | Secure Abort mode ^e | n/a |
| No | FALSE | Secure | 0b10 | X | 0 | X | - | - | n/a |

Table G2-9 Breakpoint, Watchpoint, and Vector Catch exceptions (continued)

| Debug state | Lock ^a | Current Security state | SPD ^b | Auth ^c | SUIDEN | TDE ^d | Target AArch32 mode when enabled from: | | |
|-------------|-------------------|------------------------|------------------|-------------------|--------|------------------|--|--------------------------------|-----|
| | | | | | | | PL0 | PL1 | PL2 |
| No | FALSE | Secure | 0b10 | X | 1 | X | Secure Abort mode ^e | - | n/a |
| No | FALSE | Secure | 0b11 | X | X | X | Secure Abort mode ^e | Secure Abort mode ^e | n/a |
| No | FALSE | Non-secure | 0bXX | X | X | 0 | Non-secure Abort mode | Non-secure Abort mode | - |
| No | FALSE | Non-secure | 0bXX | X | X | 1 | Hyp mode | Hyp mode | - |

- a. The value of (OSLSR_EL1.OSLK == '1' || DoubleLockStatus()).
- b. If EL3 is not implemented, behavior is as if this is 0b11.
- c. See the text that introduces this table for an explanation of the [Auth on page G2-3932](#) column. An entry of TRUE indicates that the authentication mechanism permits the debug exceptions to be taken to their default target PE mode.
- d. If HCR.TGE is 1, this bit is treated as being 1 other than for a direct read of HDCR. If EL2 is not implemented, behavior is as if TDE is 0.
- e. If EL3 is implemented and is using AArch32, Secure Abort mode is at EL3. Otherwise, Secure Abort mode is at EL1

G2.7 Pseudocode description of debug exceptions

`AArch32.DebugFault()` returns a `FaultRecord()` that indicates that a memory access has generated a debug exception.

The `AArch32.Abort()` function processes `FaultRecord()`, as described in *Abort exceptions* on page G3-4019, and generates:

- Data Abort exceptions for watchpoints.
- Prefetch Abort exceptions for all other debug exceptions.

G2.8 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch32 translation regime.

Note

When the PE is executing in EL0 using AArch32 and EL1 is using AArch64, it is using the AArch64 EL1&0 translation regime. A T32 or A32 BKPT instruction executed at EL0 can generate a Breakpoint Instruction exception that is taken to an Exception level that is using AArch64. For more information about the handling of these exceptions, see [Breakpoint Instruction exceptions on page D2-1639](#).

It contains the following subsections:

- [About Breakpoint Instruction exceptions](#).
- [Breakpoint instruction in the A32 and T32 instruction sets](#).
- [BKPT instructions as the first instruction in an IT block on page G2-3936](#).
- [Exception syndrome information and preferred return address on page G2-3936](#).
- [Pseudocode description of Breakpoint Instruction exceptions on page G2-3937](#).

G2.8.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, that this section describes, are software breakpoints. [Breakpoint exceptions on page G2-3938](#) describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D , is using AArch64 or AArch32.

Note

- EL_D is the Exception level that debug exceptions are targeting. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929](#).
 - Debuggers using breakpoint instructions must be aware of the ARMv8 rules for concurrent modification and execution of instructions. See [Concurrent modification and execution of instructions on page B2-83](#).
-

G2.8.2 Breakpoint instruction in the A32 and T32 instruction sets

The breakpoint instruction, in both instruction sets, is:

- BKPT #<immediate>

For details of the instruction encoding, see [BKPT on page F5-2621](#).

About whether the BKPT instruction is conditional

In the T32 instruction set, BKPT instructions are always unconditional.

In the A32 instruction set:

- If the condition code field is AL, the BKPT instruction is unconditional.

- If the condition code field is anything other than AL, behavior is CONstrained UNPREDICTABLE, and is one of the following:
 - The instruction is UNDEFINED.
 - The instruction is treated as a NOP instruction.
 - The instruction is executed unconditionally.
 - The instruction is executed conditionally.

G2.8.3 BKPT instructions as the first instruction in an IT block

If the first instruction in an IT block is a T32 BKPT instruction, then in an implementation that supports the ITD control, if ITD field that applies to the current Exception level is:

- 0** The BKPT instruction generates a Breakpoint Instruction exception.
- 1** The combination of IT instruction and BKPT instruction is UNDEFINED. Either the IT instruction or the BKPT instruction generates an Undefined Instruction exception.

In such an implementation, to ensure consistent behavior when making the first instruction in one or more IT blocks a BKPT instruction, the debugger must replace the IT instruction.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0.

The ITD control fields are:

HSTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

———— Note ————

T32 BKPT instructions are always unconditional, even when they are inside an IT block. See:

- [Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality on page G1-3888.](#)
- [Disabling or enabling EL2 use of AArch32 deprecated functionality on page G1-3897.](#)

G2.8.4 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information.](#)
- [Preferred return address on page G2-3937.](#)

Exception syndrome information

The PE takes a Breakpoint Instruction exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp Trap exception, if it is taken to PL2 because either **HCR.TGE** or **HDCR.TDE** is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- **DBGDSCRExt.MOE** to 0b0011, to indicate a Breakpoint Instruction exception.
- **IFSR.FS** to the code for a debug, 0b00010.
- The **IFAR** with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, **HSR**. See [Table G2-10](#).
- Sets **DBGDSCRExt.MOE** to 0b0011, to indicate a Breakpoint Instruction exception.
- Sets the **HIFAR** to an UNKNOWN value.

Table G2-10 Information recorded in the HSR

| HSR field | Information recorded |
|--|---|
| <i>Exception Class</i> , EC | The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20. |
| <i>Instruction Length</i> , IL | The PE sets this to: <ul style="list-style-type: none"> • 0 for a T32 BKPT instruction. • 1 for an A32 BKPT instruction. |
| <i>Instruction Specific Syndrome</i> , ISS | ISS[24:10] RES0. ISS[9] <i>External Abort type</i> (EA). The PE sets this to 0. ISS[8:6] RES0. ISS[5:0] <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010. |

———— **Note** —————

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-3927](#).

Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like **SVC**.

G2.8.5 Pseudocode description of Breakpoint Instruction exceptions

`AArch32.SoftwareBreakpoint()` generates a Prefetch Abort exception that is taken from AArch32 state.

G2.9 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- [About Breakpoint exceptions.](#)
- [Breakpoint types and linking of breakpoints on page G2-3939.](#)
- [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946.](#)
- [Breakpoint instruction address comparisons on page G2-3947.](#)
- [Breakpoint context comparisons on page G2-3952.](#)
- [Using breakpoints on page G2-3953.](#)
- [Exception syndrome information and preferred return address on page G2-3958.](#)
- [Pseudocode description of Breakpoint exceptions taken from AArch32 state on page G2-3959.](#)

G2.9.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint*.
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in [Breakpoint Instruction exceptions on page G2-3935](#).

An implementation can include between 2-16 hardware breakpoints. [DBGDIDR.BRPs](#) shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, [DBGBCR<n>](#). This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, [DBGBVR<n>](#). This holds a value used for breakpoint matching, that is one of:
 - An instruction virtual address.
 - A Context ID.
- If EL2 is implemented, the *Breakpoint Extended Value Register*, [DBGBXVR<n>](#), that holds a VMID value used for breakpoint matching.

These registers are numbered, so that:

- [DBGBCR1](#), [DBGBVR1](#), and [DBGBXVR1](#) are for breakpoint number one.
- [DBGBCR2](#), [DBGBVR2](#), and [DBGBXVR2](#) are for breakpoint number two.
- ...
- ...
- [DBGBCR<n>](#), [DBGBVR<n>](#), and [DBGBXVR<n>](#) are for breakpoint number <n>.

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is only generated if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the breakpoint enable control for it, `DBGBCR<n>.E`, is 1.
- The conditions specified in the `DBGBCR<n>` are met.
- The comparisons with the values held in one or both of the `DBGBVR<n>` and `DBGBXVR<n>`, as applicable, are successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

If all of these conditions are met, the breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its condition code check.
- The instruction type.

If halting is allowed and `EDSCR.HDE` is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are

- Enabled, Breakpoint debug events generate Breakpoint exceptions
- Disabled, Breakpoint debug events are ignored.

———— **Note** —————

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.

However, the behavior described also applies if breakpoints are causing entry to Debug state.

The debug exception enable controls on page G2-3926 describes the enable controls for Breakpoint debug events.

G2.9.2 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
 - An instruction address match.
 - An instruction address mismatch.
 - A Context ID match, with the value held in the `CONTEXTIDR`.
 - A VMID match, with the value held in the `VTTBR`.
 - Both a Context ID match and a VMID match.
- A breakpoint that is not context-aware. These can only be programmed to generate a Breakpoint exception on an instruction address match or an instruction address mismatch.

`DBGDIDR.CTX_CMPs` shows how many of the implemented breakpoints are context-aware breakpoints. At least one implemented breakpoint must be context-aware. The context-aware breakpoints are the highest numbered breakpoints.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match or mismatch is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Enabled for linking to another breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that only generates a Breakpoint exception if the PE is in a particular context when an instruction address match or mismatch occurs. For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Linked Context ID Match breakpoint*.
3. Link these two breakpoints together. A Breakpoint exception is only generated if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* field for a breakpoint, `DBGBCR<n>.BT`, controls the breakpoint type and whether the breakpoint is enabled for linking. If `BT[0]` is 1, the breakpoint is enabled for linking.

Figure G2-1 shows all of the possible breakpoint types that stage 1 of an AArch32 translation regime supports, and their associated BT field values.

| | | Unlinked | Linked |
|---------------------|---------------------------|--|--|
| Address breakpoints | Address Mismatch | BT == 0b0100 Unlinked Address Mismatch | BT == 0b0101 Linked Address Mismatch |
| | Address Match | BT == 0b0000 Unlinked Address Match | BT == 0b0001 Linked Address Match |
| Context breakpoints | Context ID Match | BT == 0b0010 Unlinked Context ID Match | BT == 0b0011 Linked Context ID Match |
| | VMID Match | BT == 0b1000 Unlinked VMID Match | BT == 0b1001 Linked VMID Match |
| | VMID and context ID Match | BT == 0b1010 Unlinked VMID and Context ID Match | BT == 0b1011 Linked VMID and Context ID Match |

Figure G2-1 Breakpoint types and their associated BT field values

Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See [Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-3948](#).

Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGBCR<n>.LBN`, for the Linked Address breakpoint specifies the particular Linked Context breakpoint that the Linked Address breakpoint links to, and:
 - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-3946.
 - `DBGBCR<n>.{SSC, HMC, PMC}` for the Linked Context breakpoint are ignored.
- Linked Context breakpoint types can only be linked to. The LBN field for Context breakpoints is therefore ignored.
- Linked Address breakpoints cannot link to watchpoints. The LBN field can therefore only specify another breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not context-aware, the behavior of the Linked Address breakpoint is CONstrained UNPREDICTABLE. See *Other usage constraints for Address breakpoints* on page G2-3957.
- If a Linked Address breakpoint links to an Unlinked Context breakpoint, the Linked Address breakpoint never generates any Breakpoint exceptions.
- Multiple Linked Address breakpoints can link to a single Linked Context breakpoint.

———— **Note** —————

Multiple Linked watchpoints can also link to a single Linked Context breakpoint. *Watchpoint exceptions* on page G2-3961 describes watchpoints.

These rules mean that a single Linked Context breakpoint might be linked to by all, or any combination of, the following:

- Multiple Linked Address Match breakpoints.
- Multiple Linked Address Mismatch breakpoints.
- Multiple Linked watchpoints.

It is also possible that a Linked Context breakpoint might have no breakpoints or watchpoints linked to it.

[Figure G2-2 on page G2-3942](#) shows an example of permitted breakpoint and watchpoint linking.

Figure G2-2 The role of linking in Breakpoint and Watchpoint exception generation

In [Figure G2-2](#), each Linked Address breakpoint can only generate a Breakpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the Linked Context breakpoint that it links to, are successful.

Breakpoint types defined by DBGBCRn.BT

The following list provides more detail about each breakpoint type:

0b0000, Unlinked Address Match breakpoint

Generation of a Breakpoint exception depends on both:

- [DBGBCR<n>.{SSC, HMC, PMC}](#). These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful address match, as described in [Breakpoint instruction address comparisons on page G2-3947](#).

[DBGBCR<n>.LBN](#) for this breakpoint is ignored.

0b0001, **Linked Address Match breakpoint**

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>**.{SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful address match defined by this breakpoint, as described in [Breakpoint instruction address comparisons on page G2-3947](#).
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b0010, **Unlinked Context ID Match breakpoint**

BT == 0b0010 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful Context ID match, as described in [Breakpoint context comparisons on page G2-3952](#).

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored

0b0011, **Linked Context ID Match breakpoint**

BT == 0b0011 is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see [Breakpoint instruction address comparisons on page G2-3947](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-3952](#).
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-3965](#).
 - A successful Context ID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-3952](#).

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b0100, **Unlinked Address Mismatch breakpoint**

Generation of a Breakpoint exception depends on both:

- **DBGBCR<n>**.{SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful address mismatch, as described in [Breakpoint instruction address comparisons on page G2-3947](#).

DBGBCR<n>.LBN for this breakpoint is ignored.

0b0101, Linked Address Mismatch breakpoint

Generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>.{SSC, HMC, PMC}**. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful address mismatch defined by this breakpoint, as described in [Breakpoint instruction address comparisons on page G2-3947](#).
- A successful context match defined by the Linked Context breakpoint that this breakpoint links to.

DBGBCR<n>.LBN for this breakpoint selects the Linked Context breakpoint that this breakpoint links to.

0b1000, Unlinked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- **DBGBCR<n>.{SSC, HMC, PMC}**. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See [Execution conditions for which a breakpoint generates Breakpoint exceptions on page G2-3946](#).
- A successful VMID match, as described in [Breakpoint context comparisons on page G2-3952](#).

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1001, Linked VMID Match breakpoint

BT == 0b1000 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on both:
 - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See [Breakpoint instruction address comparisons on page G2-3947](#).
 - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on both:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see [Watchpoint data address comparisons on page G2-3965](#).
 - A successful VMID match defined by this breakpoint, as described in [Breakpoint context comparisons on page G2-3952](#).

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

0b1010, Unlinked Context ID and VMID Match breakpoint

BT == 0b1010 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, generation of a Breakpoint exception depends on all of the following:

- **DBGBCR<n>.{SSC, HMC, PMC}**. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See *Execution conditions for which a breakpoint generates Breakpoint exceptions* on page G2-3946.
- A successful Context ID match, as described in *Breakpoint context comparisons* on page G2-3952.
- A successful VMID match.

Breakpoint context comparisons on page G2-3952 describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>.{LBN, BAS} for this breakpoint are ignored.

0b1011, Linked Context ID and VMID Match breakpoint

BT == 0b1011 is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-matching breakpoints, either:

- This breakpoint does not generate any Breakpoint exceptions, if no Linked breakpoints or Linked watchpoints link to it.
- Generation of a Breakpoint exception depends on all of the following:
 - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see *Breakpoint instruction address comparisons* on page G2-3947.
 - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-3952.
 - A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
 - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see *Watchpoint data address comparisons* on page G2-3965.
 - A successful Context ID match defined by this breakpoint, as described in *Breakpoint context comparisons* on page G2-3952.
 - A successful VMID match defined by this breakpoint.

Breakpoint context comparisons on page G2-3952 describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>.{LBN, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

————— **Note** —————

See *Reserved DBGBCR<n>.BT values* on page G2-3955 for the behavior of breakpoints programmed with reserved BT values.

G2.9.3 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it only generates Breakpoint exceptions for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at PL0 in Secure state.

[DBGBCR<n>](#).{SSC, HMC, PMC} define the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the breakpoint generates Breakpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

———— **Note** ————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which AArch32 modes the breakpoint generates Breakpoint exceptions in.

[Table G2-11](#) shows the valid combinations of the values of HMC, SSC, and PMC, and for each combination shows which Privilege levels breakpoints generate Breakpoint exceptions in.

In the table:

Y or - Means that a breakpoint programmed with the values of HMC, SSC and PMC shown in that row:
Y Can generate Breakpoint exceptions in AArch32 modes at that Privilege level.
- Cannot generate Breakpoint exceptions in AArch32 modes at that Privilege level.

Res Means that the combination of HMC, SSC, and PMC is reserved. See [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-3956](#).

Table G2-11 Summary of breakpoint HMC, SSC, and PMC encodings

| HMC | SSC | PMC | Security state the breakpoint is programmed to match in | PL2 ^a | PL1 | PL0 | Implementation | |
|-----|-----|-----|---|------------------|----------------|----------------|----------------|-------------------|
| | | | | | | | No EL3 | No EL2 and no EL3 |

| 1 | 11 | 00 | Non-secure | Y | - | - | - | Res if no EL2 ^c |

- Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PMC are only relevant if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PMC that generate Breakpoint exceptions at PL2 using AArch32.
- Only in User, System and Supervisor modes.
- This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PMC that this table does not show are reserved. See [Reserved HMC, SSC, and PMC combinations on page G2-3956](#).

G2.9.4 Breakpoint instruction address comparisons

Address comparisons are made for each instruction in the program flow. The following subsections describe the criteria for a successful address comparison, for:

- [Address Match breakpoints](#).
- [Address Mismatch breakpoints on page G2-3948](#).

Address Match breakpoints

An address match comparison is successful if both:

- Bits [31:2] of the current instruction virtual address are equal to `DBGBVR<n>[31:2]`.
 - The word or halfword selected by `DBGBCR<n>.BAS` matches. That is, either:
 - `DBGBCR<n>.BAS` is programmed with `0b0011` or `0b1111`, and the instruction is at a word-aligned address.
 - `DBGBCR<n>.BAS` is programmed with `0b1100`, and the instruction is not at a word-aligned address.
- See [Specifying the halfword-aligned address that an Address breakpoint matches on on page G2-3948](#).

Note
`DBGBVR<n>[1:0]` are RES0 and are ignored.

Address Mismatch breakpoints

An address mismatch comparison is successful if either:

- Bits [31:2] of the current instruction virtual address are not equal to `DBGBVR<n>[31:2]`.
 - The word or halfword selected by `DBGBCR<n>.BAS` does not match. That is, either:
 - `DBGBCR<n>.BAS` is programmed with `0b0011` or `0b1111`, and the instruction is not at a word-aligned address.
 - `DBGBCR<n>.BAS` is programmed with `0b1100`, and the instruction is at a word-aligned address.
- See *Specifying the halfword-aligned address that an Address breakpoint matches on*.

Note

- `DBGBVR<n>[1:0]` are RES0 and are ignored.
 - Address Mismatch breakpoints can be used to single-step through code. See *Using an Address Mismatch breakpoint to single-step an instruction on page G2-3953*.
-

Specifying the halfword-aligned address that an Address breakpoint matches on

For an Address breakpoint, a debugger can use the *Byte Address Selection* field, `DBGBCR<n>.BAS`, so that the address comparison is successful on one of:

- The whole word starting at address `DBGBVR<n>[31:2]:00`.
- The halfword starting at address `DBGBVR<n>[31:2]:00`.
- The halfword starting at address `((DBGBVR<n>[31:2]:00) + 2)`.

Note

The address programmed into the `DBGBVR<n>` must be word-aligned.

`DBGBCR<n>.BAS` can be used in both Address Match breakpoints and Address Mismatch breakpoints, as follows:

- For an Address Match breakpoint, `DBGBCR<n>.BAS` selects which halfword-aligned address the breakpoint must generate a Breakpoint exception for. This means that an address comparison is successful only if both of the following match:
 - The instruction address held in bits [31:2] of the `DBGBVR<n>`.
 - The halfword defined by the BAS field.That is, a successful address comparison = `DBGBVR<n>[31:2]` match AND BAS match.
- For an Address Mismatch breakpoint, `DBGBCR<n>.BAS` selects which halfword-aligned address the breakpoint must not generate a Breakpoint exception for. This means that an address comparison is successful if either or both of the following do not match:
 - The instruction address held in bits [31:2] of the `DBGBVR<n>`.
 - The halfword defined by the BAS field.That is, a successful address comparison = NOT (`DBGBVR<n>[31:2]` match AND BAS match).

The following subsections show the supported BAS values:

- *Using the BAS field in Address Match breakpoints on page G2-3949*.
- *Using the BAS field in Address Mismatch breakpoints on page G2-3950*.

For Context breakpoints, `DBGBCR<n>.BAS` is RES1 and is ignored.

Using the BAS field in Address Match breakpoints

The supported BAS values are:

- 0b0000** This value is reserved. Behavior is a CONSTRAINED UNPREDICTABLE choice of:
- The breakpoint is disabled.
 - The breakpoint behaves as if BAS is 0b0011, 0b1100, or 0b1111.
- 0b0011** The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
 - Bits [1:0] of the address are 0b00.
- This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:
- 32-bit T32 instructions at word-aligned addresses.
 - 16-bit T32 instructions at word-aligned addresses.
 - A32 instructions. These are always at word-aligned addresses.
- However, ARM recommends that a debugger uses this BAS value only for T32 instructions.
- It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$.
- 0b1100** The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
 - Bits [1:0] of the address are 0b10.
- This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for both of the following:
- 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
 - 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned.
- It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction starting at a word-aligned address.
- 0b1111** The breakpoint generates a Breakpoint exception if an instruction with an address described as follows is committed for execution:
- Bits [31:2] of the address equals `DBGBVR<n>[31:2]`.
 - Bits [1:0] of the address are 0b00.
- This means that breakpoints programmed with this BAS value generate Breakpoint exceptions for all of the following:
- 32-bit T32 instructions at word-aligned addresses.
 - 16-bit T32 instructions at word-aligned addresses.
 - A32 instructions. These are always at word-aligned addresses.
- However, ARM recommends that a debugger uses this BAS value only for A32 instructions.
- It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$.
- It is CONSTRAINED UNPREDICTABLE whether a breakpoint programmed with this BAS value generates a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$.

All other BAS values are reserved. For these reserved other values, `DBGBCR<n>.BAS[3,1]` ignore writes and read the same values as `DBGBCR<n>[2,0]` respectively. This means that the smallest instruction size a debugger can program breakpoints to match on is a halfword.

Figure G2-3 shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 2 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the halfword-aligned address ((DBGBVR<n>[31:2]:00) + 2).
- Row 6 shows that a breakpoint with a BAS value of either 0b0011 or 0b1111 generates Breakpoint exceptions for A32 instructions. A32 instructions are always at word-aligned addresses.

In the figure:

- Yes** Means that the breakpoint generates a Breakpoint exception.
- No** Means that the breakpoint does not generate a Breakpoint exception.
- UNP** Means that it is CONstrained UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints on page G2-3957*.

| | Instruction set | Size | Location of instruction ^a | | | | | | | BAS[3:0] | | | | |
|-------|-----------------|--------|--------------------------------------|----|---|----|----|----|----|----------|--------|--------|--------|-----|
| | | | -2 | -1 | 0 | +1 | +2 | +3 | +4 | +5 | 0b0011 | 0b1100 | 0b1111 | |
| Row 1 | T32 | 16-bit | | | ■ | ■ | | | | | | Yes | No | Yes |
| Row 2 | | 16-bit | | | | | ■ | ■ | | | | No | Yes | UNP |
| Row 3 | T32 | 32-bit | ■ | ■ | | | | | | | | UNP | No | UNP |
| Row 4 | | 32-bit | | | ■ | ■ | ■ | ■ | | | | Yes | UNP | Yes |
| Row 5 | | 32-bit | | | | | ■ | ■ | ■ | ■ | | No | Yes | UNP |
| Row 6 | A32 | 32-bit | | | ■ | ■ | ■ | ■ | | | | Yes | UNP | Yes |

- a. 0 means the word-aligned address held in the DBGBVRn. The other locations are as follows:
- -2 means ((DBGBVRn[31:2]:00) - 2).
 - -1 means ((DBGBVRn[31:2]:00) - 1).
 - ...
 - ...
 - +5 means ((DBGBVRn[31:2]:00) + 5).

The solid areas show the location of the instruction.

Figure G2-3 Summary of BAS field meanings for Address Match breakpoints

Using the BAS field in Address Mismatch breakpoints

An Address Mismatch breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed to match.

The supported BAS values are:

- 0b0000 The breakpoint ignores the address held in the DBGBVR<n> and generates Breakpoint exceptions for all instruction addresses.

| | |
|--------|---|
| 0b0011 | <p>The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:</p> <ul style="list-style-type: none"> • Bits [31:2] of the address equals <code>DBGBVR<n>[31:2]</code>. • Bits [1:0] of the address are <code>0b00</code>. <p>This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:</p> <ul style="list-style-type: none"> • 32-bit T32 instructions at word-aligned addresses. • 16-bit T32 instructions at word-aligned addresses. • A32 instructions. These are always at word-aligned addresses. <p>However, ARM recommends that a debugger uses this BAS value only for T32 instructions.</p> <p>It is CONstrained UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$.</p> |
| 0b1100 | <p>The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:</p> <ul style="list-style-type: none"> • Bits [31:2] equals <code>DBGBVR<n>[31:2]</code>. • Bits [1:0] of the address are <code>0b10</code>. <p>This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for either of the following:</p> <ul style="list-style-type: none"> • 32-bit T32 instructions at addresses that are halfword-aligned but not word-aligned. • 16-bit T32 instructions at addresses that are halfword-aligned but not word-aligned. <p>It is CONstrained UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 or A32 instruction at a word-aligned address.</p> |
| 0b1111 | <p>The breakpoint does not generate a Breakpoint exception if an instruction with an address described as follows is committed for execution:</p> <ul style="list-style-type: none"> • Bits [31:2] of the address equals <code>DBGBVR<n>[31:2]</code>. • Bits [1:0] of the address are <code>0b00</code>. <p>This means that breakpoints programmed with this BAS value do not generate Breakpoint exceptions for any of the following:</p> <ul style="list-style-type: none"> • 32-bit T32 instructions at word-aligned addresses. • 16-bit T32 instructions at word-aligned addresses. • A32 instructions. These are always at word-aligned addresses. <p>However, ARM recommends that a debugger uses this BAS value only for A32 instructions.</p> <p>It is CONstrained UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on the second halfword of a 32-bit T32 instruction starting at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) - 2)$.</p> <p>It is CONstrained UNPREDICTABLE whether a breakpoint programmed with this BAS value does not generate a Breakpoint exception on a 32-bit T32 instruction or a 16-bit T32 instruction at the halfword-aligned address $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$.</p> |

All other BAS values are reserved. For these reserved other values, `DBGBCR<n>.BAS[3,1]` ignore writes and read the same values as `DBGBCR<n>[2,0]` respectively. This means that the smallest instruction size that a breakpoint can never generate a Breakpoint exception for is a halfword.

[Figure G2-4 on page G2-3952](#) shows a summary of when breakpoints programmed with particular BAS values generate Breakpoint exceptions.

The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example:

- Row 1 shows that a breakpoint with a BAS value of 0b1100 generates Breakpoint exceptions for 16-bit T32 instructions starting at the word-aligned address held in the `DBGBVR<n>`.
- Row 5 shows that a breakpoint with a BAS value of 0b0011 generates Breakpoint exceptions for 32-bit T32 instructions starting at the halfword-aligned address immediately after the word aligned address held in the `DBGBVR<n>`.

In the figure:

Yes Means that the breakpoint does generate a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONstrained UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See *Other usage constraints for Address breakpoints on page G2-3957*

| | Instruction set | Size | Location of instruction ^a | | | | | | | BAS[3:0] | | | | | |
|-------|-----------------|--------|--------------------------------------|----|---|----|----|----|----|----------|--------|--------|--------|--------|-----|
| | | | -2 | -1 | 0 | +1 | +2 | +3 | +4 | +5 | 0b0000 | 0b0011 | 0b1100 | 0b1111 | |
| Row 1 | T32 | 16-bit | | | ■ | ■ | | | | | | Yes | No | Yes | No |
| Row 2 | | 16-bit | | | | | ■ | ■ | | | | Yes | Yes | No | UNP |
| Row 3 | T32 | 32-bit | ■ | ■ | ■ | ■ | | | | | | Yes | UNP | Yes | UNP |

- a. 0 means the word-aligned address held in the `DBGBVRn`. The other locations are as follows:
- -2 means $((\text{DBGBVRn}[31:2]:00) - 2)$.
 - -1 means $((\text{DBGBVRn}[31:2]:00) - 1)$.
 - ...
 - ...
 - +5 means $((\text{DBGBVRn}[31:2]:00) + 5)$.

The solid areas show the location of the instruction.

Figure G2-4 Summary of BAS field meanings for Address Mismatch breakpoints

G2.9.5 Breakpoint context comparisons

The breakpoint type defined by `DBGBCR<n>.BT` determines what context comparison is required, if any. [Table G2-12](#) shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table G2-12 Breakpoint context comparison tests

| <code>DBGBCR<n>.BT</code> | Test required for successful context comparison |
|---------------------------------|---|
| 0b001x | <code>CONTEXTIDR</code> value matches <code>DBGBVR<n>.ContextID</code> value |
| 0b100x | <code>VTTBR.VMID</code> value matches <code>DBGBXVR<n>.VMID</code> value |
| 0b101x | <code>CONTEXTIDR</code> value matches <code>DBGBVR<n>.ContextID</code> value and <code>VTTBR.VMID</code> value matches <code>DBGBXVR<n>.VMID</code> value |

No context comparison is required for other valid `DBGBCR<n>.BT` values.

Context breakpoints do not generate Breakpoint exceptions when execution is in EL2.

The following Context breakpoint types do not generate Breakpoint exceptions in Secure state:

- VMID Match breakpoints.
- VMID and Context ID Match breakpoints.

Note

- For all Context breakpoints, `DBGBCR<n>.BAS` is RES1 and is ignored.
- For Linked Context breakpoints, `DBGBCR<n>.{LBN, SSC, HMC, PMC}` are RES0 and are ignored.

G2.9.6 Using breakpoints

This section contains the following:

- [Using an Address Mismatch breakpoint to single-step an instruction.](#)
- [ITD control effects on address breakpoints on the first instruction in an IT block on page G2-3954.](#)
- [Usage constraints on page G2-3955.](#)

Using an Address Mismatch breakpoint to single-step an instruction

In execution conditions that an Address Mismatch breakpoint matches, defined by `DBGBCR<n>.{LBN, SSC, PMC}`, the breakpoint generates Breakpoint exceptions for all instructions committed for execution, except the instruction whose address the breakpoint is programmed with. [Figure G2-5](#) shows an example of Address Mismatch breakpoint operation, for an Address Mismatch breakpoint programmed with address `0x1014`.

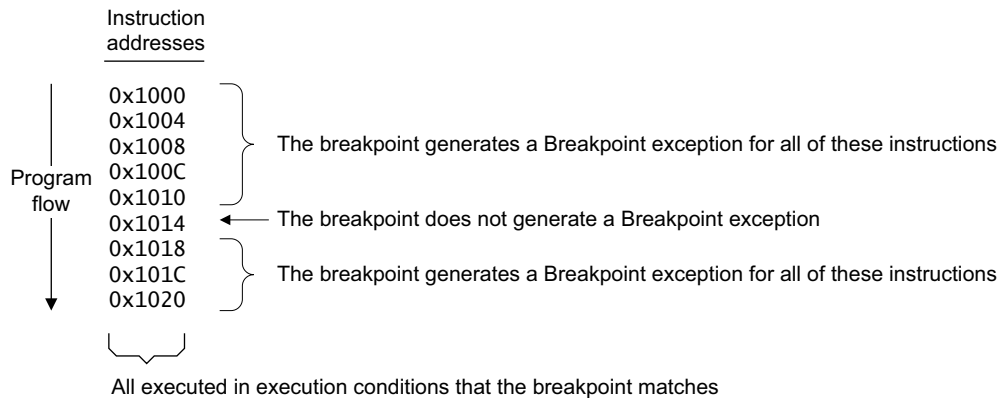

Figure G2-5 Operation of an Address Mismatch breakpoint

This means that an Address Mismatch breakpoint can be used to single-step an instruction.

In the example shown in [Figure G2-5](#):

- If the target of a branch is an instruction other than the instruction at address `0x1014`, the breakpoint generates a Breakpoint exception when the instruction is committed for execution.
- If the target of a branch is the instruction at address `0x1014`, the PE executes the instruction at `0x1014` and the breakpoint does not generate a Breakpoint exception until the instruction at address `0x1018` is committed for execution. The instruction at address `0x1014` is therefore single-stepped.

However, if the instruction at `0x1014` generates a synchronous exception, or if the PE takes an asynchronous exception while the instruction is being stepped, the breakpoint is evaluated again after taking the exception. This means that behavior is as follows:

- If the exception handler executes in execution conditions that the breakpoint matches, the breakpoint generates a Breakpoint exception for the exception vector, because the exception vector is not address `0x1014`. This means that software execution steps into the exception.
- If the exception handler executes in execution conditions that the breakpoint does not match, the breakpoint does not generate any Breakpoint exceptions after the PE has taken the exception, until the exception handler completes and executes an exception return instruction. The effect is to step over the exception. Whether the instruction is stepped again depends on whether the target of the exception return instruction is the instruction at `0x1014` or the instruction at `0x1018`.

If the instruction at $0x1014$ is single-stepped and branches to itself, it is **CONSTRAINED UNPREDICTABLE** whether the breakpoint generates a Breakpoint exception after the PE has executed the branch.

This means that an instruction is only single-stepped if it is the target of a branch instruction and its address matches the address the breakpoint is programmed for. In the example shown in [Figure G2-5 on page G2-3953](#), this is $0x1014$.

Usually this branch instruction is an exception return instruction that changes PE mode, branching from a PE mode in which the breakpoint does not generate a Breakpoint exception. A branch instruction that does not change PE mode would itself generate a Breakpoint exception. However, it might be a branch-to-self instruction as described above.

Because Address Mismatch breakpoints can single-step instructions, the behavior of an address mismatch Breakpoint exception is similar to the behavior of an AArch64 Software Step exception.

Note

- The example shown in [Figure G2-5 on page G2-3953](#) assumes an A32 instruction. The same behavior applies for both 32-bit and 16-bit T32 instructions.
- Software Step exceptions are the highest priority exception. Breakpoint exceptions are lower priority. See [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#).

ITD control effects on address breakpoints on the first instruction in an IT block

In an implementation that supports the ITD control, if the value of the ITD field that applies to the current Exception level is 1, all of the following are true:

- An IT instruction can only be used to apply to one 16-bit T32 instruction.
- Only certain combinations of an IT instruction and second single 16-bit T32 instruction are permitted.
- For a permitted combination, it is **IMPLEMENTATION DEFINED** whether the implementation treats the combination as:
 - A pair of 16-bit instructions.
 - One 32-bit instruction.

If the implementation treats the combination as one 32-bit instruction, then as described in [Other usage constraints for Address breakpoints on page G2-3957](#), an Address breakpoint might not generate a Breakpoint exception for an address match only on the second halfword of the instruction.

For this reason, if the ITD bit associated with the current Exception level is 1, ARM recommends that a debugger that wants to program a breakpoint to match on the second T32 instruction programs it to match on the IT instruction instead.

However, if returning from an exception whose preferred return address is the address of the second T32 instruction, then because the debugger is aware that the implementation has treated the combination as a pair of 16-bit instructions, the debugger is permitted to program the breakpoint to match on the second T32 instruction.

The ITD control fields are:

HSCTLR.ITD Applies to execution at EL2 when EL2 is using AArch32.

SCTLR.ITD Applies to execution at EL0 or EL1 when EL1 is using AArch32.

SCTLR_EL1.ITD

Applies to execution at EL0 using AArch32 when EL1 is using AArch64.

An implementation that does not support the ITD control behaves as if the value of the ITD field is 0, and therefore the information in this section does not apply to such an implementation.

Note

Programming the breakpoint to match on the second T32 instruction might be necessary when using an Address Mismatch breakpoint for single stepping.

Usage constraints

See the following:

- [Reserved DBGBCR<n>.BT values.](#)
- [Reserved DBGBCR<n>.{SSC, HMC, PMC} values on page G2-3956.](#)
- [Reserved DBGBCR<n>.BAS values on page G2-3956.](#)
- [Reserved DBGBCR<n>.LBN values on page G2-3957.](#)
- [Other usage constraints for Address breakpoints on page G2-3957.](#)
- [Other usage constraints for Context breakpoints on page G2-3958.](#)

Reserved DBGBCR<n>.BT values

Table G2-13 shows when particular DBGBCR<n>.BT values are reserved.

Table G2-13 Reserved BT values

| BT value | Breakpoint type | Reserved |
|----------|---------------------------|--|
| 0b001x | Context ID Match | For non context-aware breakpoints. |
| 0b010x | Address Mismatch | If EDSCR.HDE is 1 and halting is allowed. |
| 0b011x | - | Always. |
| 0b100x | VMID Match | For non context-aware breakpoints, or if EL2 is not implemented. |
| 0b101x | Context ID and VMID Match | |
| 0b11xx | - | Always. |

If a breakpoint is programmed with one of these reserved BT values:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BT value that is not reserved, other than for a direct or external read of DBGBCR<n>.
- For a direct or external read of DBGBCR<n>, if the reserved BT value:
 - Has no function for any execution conditions, the value read back is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the BT value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved BT values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved *DBGBCR*<*n*>.{*SSC*, *HMC*, *PMC*} values

Table G2-14 shows when particular combinations of *DBGBCR*<*n*>.{*SSC*, *HMC*, *PMC*} are reserved in stage 1 of an AArch32 translation regime.

Table G2-14 Reserved HMC, SSC, and PMC combinations

| HMC, SSC, and PMC combination | Reserved |
|--|---|
| All combinations with SSC set to 0b01 or 0b10. | When EL3 is not implemented and EL2 is implemented. |
| Any combination where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When both of EL2 and EL3 are not implemented. |
| The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When EL2 is not implemented. |
| Combinations not included in Table G2-11 on page G2-3946. | Always |

For all breakpoints except Linked Context breakpoints, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
 - The breakpoint must behave as if it is disabled.
 - A direct or external read of *DBGBCR*<*n*>.{*SSC*, *HMC*, *PMC*} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
 - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
 - A direct or external read of *DBGBCR*<*n*>.{*SSC*, *HMC*, *PMC*} returns UNKNOWN values.

If the breakpoint is a Linked Context breakpoint, then:

- The values of HMC, SSC, and PMC are ignored.
- A direct or external read of *DBGBCR*<*n*>.{*SSC*, *HMC*, *PMC*} returns UNKNOWN values

The behavior of breakpoints with reserved combinations of HMC, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved *DBGBCR*<*n*>.*BAS* values

For all Context breakpoints

DBGBCR<*n*>.*BAS* is RES1 and is ignored.

For all Address breakpoints

The supported values of the *BAS* field for the Address Match and Address Mismatch breakpoints are shown in *Specifying the halfword-aligned address that an Address breakpoint matches on* on page G2-3948.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
 - Disabled.
 - Programmed with a BAS value that is not reserved, other than for a direct or external read of `DBGBCR<n>`.
- A direct or external read of `DBGBCR<n>.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved `DBGBCR<n>.LBN` values

For all Context breakpoints

`DBGBCR<n>.LBN` reads UNKNOWN and its value is ignored.

For Linked Address breakpoints

A Linked Address breakpoint must link to a context-aware breakpoint. For a Linked Address breakpoint, any `DBGBCR<n>.LBN` value that is not for a context-aware breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of `DBGBCR<n>.LBN` return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked Address breakpoint that links to a breakpoint that is implemented and that is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked Address breakpoints

`DBGBCR<n>.LBN` reads UNKNOWN and its value is ignored.

Other usage constraints for Address breakpoints

For all Address breakpoints

- `DBGBVR<n>[1:0]` are RES0 and are ignored.
- The `DBGXVR<n>` is ignored.

For Address Match breakpoints

- For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
- If `DBGBCR<n>.BAS` is 0b1111, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address $((\text{DBGBVR}\langle n \rangle[31:2]:00) + 2)$. For T32 instructions, ARM recommends that the debugger programs the BAS field with either 0b0011 or 0b1100.

For Address Mismatch breakpoints

The constraints are the same as those described in *For Address Match breakpoints*, except that if two Address Mismatch breakpoints are programmed to match in the same Exception level and Security state, it is CONSTRAINED UNPREDICTABLE whether or not the instruction is stepped or a Breakpoint debug even is generated.

Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of `DBGBVR<n>` and `DBGBXVR<n>` that are not used to specify Context ID or VMID are RES0 and are ignored.

———— **Note** —————

This means that for Context ID Match breakpoints, the `DBGBXVR<n>` is RES0 and is ignored, and for VMID Match breakpoints, the `DBGBVR<n>` is RES0 and is ignored.

—————

For Linked Context breakpoints

If no Linked Address breakpoints or Linked Watchpoints link to a Linked Context breakpoint, the Linked Context breakpoint does not generate any Breakpoint exceptions.

G2.9.7 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information.](#)
- [Preferred return address on page G2-3959.](#)

Exception syndrome information

The PE takes a Breakpoint exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because `HCR.TGE` or `HDCCR.TDE` is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- `DBGDSCRExt.MOE` to 0b0001, to indicate a Breakpoint exception.
- `IFSR.FS` to the code for a debug exception, 0b00010.
- The `IFAR` with an UNKNOWN value.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, **HSR**. See [Table G2-15](#).
- Sets **DBGDSCRExt.MOE** to 0b0001, to indicate a Breakpoint exception.
- Sets the **HIFAR** to an UNKNOWN value.

Table G2-15 Information recorded in the HSR

| HSR field | Information recorded |
|--|---|
| <i>Exception Class</i> , EC | The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, 0x20. |
| <i>Instruction Length</i> , IL | The PE sets this to 1. |
| <i>Instruction Specific Syndrome</i> , ISS | ISS[24:10] RES0. ISS[9] <i>External Abort type</i> (EA). The PE sets this to 0. ISS[8:6] RES0. ISS[5:0] <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, 0b100010. |

Note

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-3927](#).

Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.9.8 Pseudocode description of Breakpoint exceptions taken from AArch32 state

AArch32.BreakpointValueMatch() returns a pair of results:

- A result for Address Match and Context breakpoints.
- A result for Address Mismatch breakpoints.

AArch32.StateMatch() tests the values in **DBGBCR<n>**.{SSC, HMC, PMC} and, if the breakpoint links to a Linked Context breakpoint, also tests the Linked Context breakpoint.

AArch32.BreakpointMatch() tests a committed instruction against all breakpoints.

AArch32.CheckBreakpoint() generates a **FaultRecord**. A Breakpoint exception is taken if all of the following are true:

- **DBGDSCRExt.MDBGen** is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929](#).
- All of the conditions required for Breakpoint exception generation are met. See [About Breakpoint exceptions on page G2-3938](#).

Note

AArch32.CheckBreakpoint() might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32.Abort()` function processes the `FaultRecord` object returned by `AArch32.CheckBreakpoint()`, as described in *Abort exceptions on page G3-4019*. When a Breakpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Prefetch Abort exception.

G2.10 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

This section contains the following subsections:

- [About Watchpoint exceptions.](#)
- [Watchpoint types and linking of watchpoints on page G2-3963.](#)
- [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-3964.](#)
- [Watchpoint data address comparisons on page G2-3965.](#)
- [Determining the memory location that caused a Watchpoint exception on page G2-3969.](#)
- [Watchpoint behavior on other instructions on page G2-3970.](#)
- [Usage constraints on page G2-3970.](#)
- [Exception syndrome information and preferred return address on page G2-3973.](#)
- [Pseudocode description of Watchpoint exceptions taken from AArch32 state on page G2-3974.](#)

G2.10.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-16 watchpoints. In an implementation, [DBGDIDR.WRPs](#) shows how many are implemented.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, [DBGWCR<n>](#). This holds control information for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, [DBGWVR<n>](#). This holds the data virtual address used for watchpoint matching.

The registers are numbered, so that:

- [DBGWCR1](#) and [DBGWVR1](#) are for watchpoint number one.
- [DBGWCR2](#) and [DBGWVR2](#) are for watchpoint number two.
- ...
- ...
- [DBGWCRn](#) and [DBGWVRn](#) are for watchpoint number n.

A watchpoint can:

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Linked Context breakpoint*, so that a Watchpoint debug event is only generated if the PE is in a particular context when the address match occurs.

A single watchpoint can be programmed to match on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, `DBGWCR<n>.BAS`, to select the bytes. See [Programming a watchpoint with eight bytes or fewer on page G2-3966](#).
- Eight bytes to 2GB, provided that both of the following are true:
 - The number of bytes is a power-of-two.
 - The range starts at an address that is aligned to the range size.A debugger uses the *MASK* field, `DBGWCR<n>.MASK`, to program a watchpoint with eight bytes to 2GB. See [Programming a watchpoint with eight or more bytes on page G2-3968](#).

A debugger must use either the *BAS* field or the *MASK* field. If it uses both, whether the watchpoint generates Watchpoint exceptions is `CONSTRAINED UNPREDICTABLE`. See [Programming dependencies of the *BAS* and *MASK* fields on page G2-3971](#).

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The watchpoint is enabled. That is, the watchpoint enable control for it, `DBGWCR<n>.E`, is 1.
- The conditions specified in the `DBGWCR<n>` are met.
- The comparison with the address held in the `DBGWVR<n>` is successful.
- If the watchpoint links to a Linked Context breakpoint, the comparison or comparisons made by the Linked Context breakpoint are successful. See [on page G2-3942](#) shows this. See also [Breakpoint context comparisons on page G2-3952](#).
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its condition code check.

If halting is allowed and `EDSCR.HDE` is 1, Watchpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

———— **Note** —————

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.

However, the behavior described also applies if watchpoints are causing entry to Debug state.

[The debug exception enable controls on page G2-3926](#) describes the enable controls for Watchpoint debug events.

G2.10.2 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that it is either:

- Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
- Enabled for linking to a Linked Context breakpoint. In this case, the watchpoint is called a *Linked watchpoint*.

When a Linked watchpoint links to a Linked Context breakpoint, the Linked watchpoint only generates a Watchpoint exception if the PE is in a particular context when the data address match occurs. For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is only generated if both the data address matches and the VMID matches.

The *Watchpoint Type* field for a watchpoint, `DBGWCR<n>.WT`, controls whether the watchpoint is enabled for linking. If `DBGWCR<n>.WT` is 1, the watchpoint is enabled for linking.

Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can link to any type of Linked Context breakpoint. The *Linked Breakpoint Number* field, `DBGWCR<n>.LBN`, for the Linked watchpoint specifies the particular Linked Context breakpoint that the Linked watchpoint links to, and:
 - `DBGWCR<n>.WT`, {SSC, HMC, PAC} for the Linked watchpoint define the execution conditions that the watchpoint generates Watchpoint exceptions for. See [Execution conditions for which a watchpoint generates Watchpoint exceptions on page G2-3964](#).
 - `DBGBCR<n>`, {SSC, HMC, PMC} for the Linked Context breakpoint are ignored.
- A Linked watchpoint cannot link to another watchpoint. The LBN field can therefore only specify a breakpoint.
- If a Linked watchpoint links to a breakpoint that is not context-aware, the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE. See [Usage constraints on page G2-3970](#)
- If a Linked watchpoint links to an Unlinked Context breakpoint, the Linked watchpoint never generates any Watchpoint exceptions.
- Multiple Linked watchpoints can link to a single Linked Context breakpoint.

Note

Multiple Address breakpoints can also link to a single Linked Context breakpoint. [Breakpoint exceptions on page G2-3938](#) describes breakpoints.

Figure G2-2 on page G2-3942 shows an example of permitted watchpoint linking.

G2.10.3 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it only generates Watchpoint exceptions for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only when the PE is executing at EL2.

`DBGWCR<n>.{SSC, HMC, PAC}` define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control, SSC

Controls whether the watchpoint generates Watchpoint exceptions only in Secure state, only in Non-secure state, or in both Security states.

———— **Note** —————

This is determined by the Security state of the PE, not from the NS attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Privilege level the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access, not to the Exception level or Privilege level at which the access was made.

———— **Note** —————

This means that, if the PE executes a Load unprivileged or Store unprivileged instruction at PL1, the resulting data access triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on PLO accesses.
- All other conditions for generating the watchpoint are met.

Example A32/T32 Load unprivileged and Store unprivileged instructions are LDRT and STRT.

Table G2-16 on page G2-3965 shows the valid combinations of HMC, SSC, and PAC, and for each combination shows which Privilege levels watchpoints generate Watchpoint exceptions in.

In the table:

- Y or -** Means that a watchpoint programmed with the values of HMC, SSC, and PAC shown in that row:
- Y** Can generate Watchpoint exceptions at that Privilege level.
 - Cannot generate Watchpoint exceptions at that Privilege level.
- Res** Means that the combination of HMC, SSC, and PAC is reserved. See *Reserved DBGWCR<n>.{SSC, HMC, PAC} values* on page G2-3971.

Table G2-16 Summary of watchpoint HMC, SSC, and PAC encodings

| HMC | SSC | PAC | Security state the watchpoint is programmed to match in | PL2 ^a | PL1 | PL0 | Implementation | |
|-----|-----|-----|---|------------------|-----|-----|----------------|----------------------------|
| | | | | | | | No EL3 | No EL2 and no EL3 |
| 0 | 00 | 01 | Both | - | Y | - | - | - |
| 0 | 00 | 10 | | - | - | Y | - | - |
| 0 | 00 | 11 | | - | Y | Y | - | - |
| 0 | 01 | 01 | Non-secure | - | Y | - | Res | Res |
| 0 | 01 | 10 | | - | - | Y | Res | Res |
| 0 | 01 | 11 | | - | Y | Y | Res | Res |
| 0 | 10 | 01 | Secure | - | Y | - | Res | Res |
| 0 | 10 | 10 | | - | - | Y | Res | Res |
| 0 | 10 | 11 | | - | Y | Y | Res | Res |
| 1 | 00 | 01 | Both | Y | Y | - | - | Res |
| 1 | 00 | 11 | | Y | Y | Y | - | Res |
| 1 | 01 | 01 | Non-secure | Y | Y | - | Res | Res |
| 1 | 01 | 11 | | Y | Y | Y | Res | Res |
| 1 | 10 | 01 | Secure | - | Y | - | Res | Res |
| 1 | 10 | 11 | | - | Y | Y | Res | Res |
| 1 | 11 | 00 | Non-secure | Y | - | - | - | Res if no EL2 ^b |

- a. Debug exceptions are not generated at PL2 using AArch32. This means that these combinations of HMC, SSC, and PAC are only relevant if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSC, and PAC that generate Watchpoint exceptions at PL2 using AArch32.
- b. This encoding is only reserved when EL2 is not implemented, regardless of whether EL3 is implemented.

All combinations of HMC, SSC, and PAC that this table does not show are reserved. See *Reserved DBGWCR<n>.{SSC, HMC, PAC} values on page G2-3971*.

G2.10.4 Watchpoint data address comparisons

An address comparison is successful if bits [31:2] of the current data virtual address are equal to `DBGWVR<n>[31:2]`, taking into account all of the following:

- The size of the access. See *Size of the data access on page G2-3966*.
- The bytes selected by `DBGWVR<n>.BAS`. See *Programming a watchpoint with eight bytes or fewer on page G2-3966*.
- Any address ranges indicated by `DBGWVR<n>.MASK`. See *Programming a watchpoint with eight or more bytes on page G2-3968*.

Note
`DBGWVR<n>[1:0]` are RES0 and are ignored.

Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each access must be taken into account. See [Example G2-1](#).

Example G2-1

1. A debugger programs a watchpoint to generate Watchpoint exceptions only when the byte at address 0x1009 is accessed.
2. The PE accesses the unaligned doubleword starting at address 0x1003.

In this scenario, the watchpoint must generate a Watchpoint exception.

The size of data accesses initiated by DCIMVAC instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
 - The size that [CTR.DminLine](#) defines.
 - 2KB.
- A power-of-two.

The lowest address accessed by a DCIMVAC instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.

The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also, [Watchpoint behavior on accesses by DCIMVAC instructions on page G2-3970](#).

Programming a watchpoint with eight bytes or fewer

The Byte Address Select field, [DBGWCR<n>.BAS](#), selects which bytes in the doubleword starting at the address contained in the [DBGWVR<n>](#) the watchpoint generates Watchpoint exceptions for.

If the address programmed into the [DBGWVR<n>](#) is:

- Doubleword-aligned:
 - All eight bits of [DBGWCR<n>.BAS](#) are used, and the descriptions given in [Table G2-17](#) apply.
- Word-aligned but not doubleword-aligned:
 - Only [DBGWCR<n>.BAS\[3:0\]](#) are used, and the descriptions given in [Table G2-18 on page G2-3967](#) apply. In this case, [DBGWCR<n>.BAS\[7:4\]](#) are RES0.

Table G2-17 Supported BAS values when the DBGWVRn address alignment is doubleword

| BAS value | Description |
|-------------|---|
| 0b00000000 | Watchpoint never generates a Watchpoint exception |
| BAS[0] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:000 is accessed |
| BAS[1] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:001 is accessed |
| BAS[2] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:010 is accessed |
| BAS[3] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:011 is accessed |
| BAS[4] == 1 | Generates a Watchpoint exception if byte at address DBGWVR<n>[31:3]:100 is accessed |

Table G2-17 Supported BAS values when the DBGWVRn address alignment is doubleword

| BAS value | Description |
|-------------|--|
| BAS[5] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:3]:101</code> is accessed |
| BAS[6] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:3]:110</code> is accessed |
| BAS[7] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:3]:111</code> is accessed |

Table G2-18 Supported BAS values when the DBGWVRn address alignment is word

| BAS value ^a | Description |
|------------------------|---|
| 0b00000000 | Watchpoint never generates a Watchpoint exception |
| BAS[0] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:2]:00</code> is accessed |
| BAS[1] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:2]:01</code> is accessed |
| BAS[2] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:2]:10</code> is accessed |
| BAS[3] == 1 | Generates a Watchpoint exception if byte at address <code>DBGWVR<n>[31:2]:11</code> is accessed |

a. `DBGWCR<n>.BAS[7:4]` are RES0.

If the BAS field is programmed with more than one byte, the bytes that it is programmed with must be contiguous. For watchpoint behavior when its BAS field is programmed with non-contiguous bytes, see *Other usage constraints on page G2-3972*.

When programming the BAS field with anything other than 0b11111111, a debugger must also program `DBGWCR<n>.MASK` to be 0b00000. See *Programming dependencies of the BAS and MASK fields on page G2-3971*.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the `DBGWVR<n>[31:3]`. See *Example G2-1 on page G2-3966*.

The following are some example configurations of the BAS field:

- To program a watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
 - `DBGWVR<n>` with 0x1000.
 - `DBGWCR<n>_ELI.BAS` to be 0b00001000.
- To program a watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
 - `DBGWVR<n>` with 0x2000.
 - `DBGWCR<n>_ELI.BAS` to be 0b00111000.
- If the address programmed into the `DBGWVR<n>` is doubleword-aligned:
 - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program `DBGWCR<n>.BAS` to be 0b00001111.
 - To generate a Watchpoint exception when any byte in the word starting at address `DBGWVR<n>[31:3]:100` is accessed, program `DBGWCR<n>.BAS` to be 0b11110000.

Note

ARM deprecates programming a `DBGWVR<n>` with an address that is not doubleword-aligned.

Programming a watchpoint with eight or more bytes

A debugger can use the `MASK` field, `DBGWCR<n>.MASK`, to program a single watchpoint with a data address range. The data address range must meet all of the following criteria:

- It is a size that is both:
 - A power-of-two.
 - A minimum of eight bytes.
 - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The `MASK` field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked:

| | | |
|-------------|---------|--|
| MASK | 0b00000 | No bits are masked. |
| | 0b00001 | Reserved. |
| | 0b00010 | Reserved. |
| | 0b00011 | Three least significant bits are masked. |
| | 0b00100 | Four least significant bits are masked. |
| | 0b00101 | Five least significant bits are masked. |
| | ... | ... |
| | 0b11111 | 31 least significant bits are masked. |

If n least significant address bits are masked, the watchpoint generates a Watchpoint exception on all of the following:

- Address `DBGWVR<n>[31:n]:000...`
- Address `DBGWVR<n>[31:n]:111...`
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between `DBGWVR<n>[31:4]:0000` and `DBGWVR<n>[31:4]:1111`, including these addresses.

Note

- The most significant bit cannot be masked. This means that the full address cannot be masked.
 - For watchpoint behavior when its `MASK` field is programmed with a reserved value, see [Reserved `DBGWCR<n>.MASK` values on page G2-3972](#).
-

When masking address bits, a debugger must both:

- Program `DBGWCR<n>.BAS` to be 0b11111111. See [Programming dependencies of the BAS and MASK fields on page G2-3971](#).
- In the `DBGWVR<n>`, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see [Other usage constraints on page G2-3972](#).

G2.10.5 Determining the memory location that caused a Watchpoint exception

On a Watchpoint exception, the PE records an address in a *Fault Address Register* that the debugger can use to determine the memory location that triggered the watchpoint.

The Fault Address Register (FAR) used is either:

- [DFAR](#), if the exception is taken to PL1.
- [HDFAR](#), if the exception is taken to PL2.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

On entering Debug state on a Watchpoint debug event, the PE records the address in the [EDWAR](#).

Note

If Debug state was entered from AArch32 state, then [EDWAR](#)[63:32] is UNKNOWN and must be ignored by the debugger.

For more information, see the subsections that follow. These are:

- [Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions.](#)
- [Address recorded for Watchpoint exceptions generated by Data Cache instructions on page G2-3970.](#)

Address recorded for Watchpoint exceptions generated by instructions other than Data Cache instructions

The address recorded must be both:

- From the inclusive range between:
 - The lowest address accessed by the memory access that triggered the watchpoint.
 - The highest *watchpointed address* accessed by the memory access. A watchpointed address is an address that the watchpoint is watching.
- Within a naturally-aligned block of memory that is all of the following:
 - A power-of-two size.
 - No larger than 2KB.
 - No larger than the block size used by the A64 [DC ZVA](#) instruction.

Note

There are no architectural means to discover the A64 [DC ZVA](#) instruction block size from AArch32 state.

- Contains a watchpointed address accessed by the memory access.

The size of the block is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

Example G2-2 Address recorded for a watchpoint programmed on 0x8019

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte 0x8019.

An A32 load multiple instruction then loads nine registers starting from address 0x8004 upwards. This triggers the watchpoint.

If the DC ZVA block size is:

- 32 bytes, the address that the PE records must be between 0x8004 and 0x8019 inclusive.
 - 16 bytes, the address that the PE records must be between 0x8010 and 0x8019 inclusive.
-

Address recorded for Watchpoint exceptions generated by Data Cache instructions

The address recorded is the address passed to the instruction. This means that the address recorded might be higher than the address of the location that triggered the watchpoint.

G2.10.6 Watchpoint behavior on other instructions

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Preload instructions.
- All data cache maintenance instructions except DCIMVAC.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also:

- [Watchpoint behavior on accesses by Store-Exclusive instructions.](#)
- [Watchpoint behavior on accesses by DCIMVAC instructions.](#)

Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an exclusive monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

Watchpoint behavior on accesses by DCIMVAC instructions

It is IMPLEMENTATION DEFINED whether DCIMVAC operations can generate Watchpoint exceptions. If they can, they are treated as data stores. This means that for a watchpoint to match on an access caused by a DCIMVAC instruction, the debugger must program `DBGWCR<n>.LSC` to be one of the following:

- 10** Match on data stores only.
- 11** Match on data stores and data loads.

———— Note —————

For the size of data accesses performed by DCIMVAC instructions, see [Watchpoint data address comparisons on page G2-3965](#). The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

G2.10.7 Usage constraints

See the following:

- [Reserved `DBGWCR<n>.{SSC, HMC, PAC}` values on page G2-3971.](#)
- [Reserved `DBGWCR<n>.LBN` values on page G2-3971.](#)
- [Programming dependencies of the `BAS` and `MASK` fields on page G2-3971.](#)
- [Reserved `DBGWCR<n>.BAS` values on page G2-3972.](#)
- [Reserved `DBGWCR<n>.MASK` values on page G2-3972.](#)
- [Other usage constraints on page G2-3972.](#)

Reserved DBGWCR<n>.{SSC, HMC, PAC} values

Table G2-19 shows when particular combinations of DBGWCR<n>.{SSC, HMC, PAC} are reserved.

Table G2-19 Reserved SSC, HMC, and PAC combinations

| HMC, SSC, and PMC combination | Reserved |
|---|---|
| All combinations with SSC set to 0b01 or 0b10. | When EL3 is not implemented and EL2 is implemented. |
| All combinations where HMC or SSC is nonzero, except for the combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When both of EL2 and EL3 are not implemented |
| The combination with HMC set to 1, SSC set to 0b11, and PMC set to 0b00. | When EL2 is not implemented |
| Combinations not included in Table G2-16 on page G2-3965. | Always |

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>.
- For a direct or external read of DBGWCR<n>, if the reserved combination:
 - Has no function for any execution conditions, the value read back for each of SSC, HMC, and PMC is UNKNOWN.
 - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Reserved DBGWCR<n>.LBN values

For Linked watchpoints

A Linked watchpoint must link to a context-aware breakpoint. For a Linked watchpoint, any DBGWCR<n>.LBN value that is not for a context-aware breakpoint is reserved.

If a Linked watchpoint links to a breakpoint that is not implemented, or that is not context-aware, then reads of DBGWCR<n>.LBN return an UNKNOWN value and the behavior is CONSTRAINED UNPREDICTABLE. The Linked watchpoint behaves as if it is either:

- Disabled.
- Linked to an UNKNOWN context-aware breakpoint.

If a Linked watchpoint links to a breakpoint that is implemented and is context-aware, but that is either not enabled or not programmed as a Linked Context breakpoint, it behaves as if it is disabled.

For Unlinked watchpoints

For Unlinked watchpoints, DBGWCR<n>.LBN reads UNKNOWN and its value is ignored.

Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n> the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be 0b11111111, so that all bytes in the doubleword or word are selected.
- BAS field, it must program MASK to be 0b000000, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is non-zero and a BAS field that is not set to 0b11111111, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

Reserved DBGWCR<n>.BAS values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- n is a non-zero positive integer less-than-or-equal-to 8.
- m is a positive integer less-than 8.
- n+m is less-than-or-equal-to 8.

All other values are reserved.

———— **Note** —————

If x is zero, then `Zeros(x)` is an empty bitstring.

If `DBGWVR<n>[2]` is 1, `DBGWCR<n>.BAS[7:4]` are RES0 and are ignored.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the `DBGWVR<n>`.
- A direct or external read of `DBGWCR<n>.BAS` returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

Reserved DBGWCR<n>.MASK values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
 - Disabled.
 - Programmed with an UNKNOWN value that is not reserved, that might be 0b000000, other than for a direct or external read of `DBGWCR<n>`.
- A direct or external read of `DBGWCR<n>.MASK` returns an UNKNOWN value.

Other usage constraints

For all watchpoints:

- `DBGWVR<n>[1:0]` are RES0 and are ignored.
- If `DBGWCR<n>.MASK` is nonzero, and any masked bits of `DBGWVR<n>` are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if `DBGWCR<n>.LSC` is 0b00.

G2.10.8 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information](#).
- [Preferred return address on page G2-3974](#).

Exception syndrome information

The PE takes a Watchpoint exception as either:

- A Data Abort exception, if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

Abort mode

The PE sets all of the following:

- [DBGDSCRExt.MOE](#) to 0b1010, to indicate a Watchpoint exception.
- [DFSR.CM](#) to indicate whether a cache maintenance instruction caused the exception.
- [DFSR.WnR](#) to indicate whether the exception was generated on a read instruction or a write instruction.
- [DFAR](#) to an address that the debugger can use to determine the memory location that triggered the watchpoint. See [Determining the memory location that caused a Watchpoint exception on page G2-3969](#).

In addition, if using the:

- Short-descriptor format, the PE sets [DFSR.FS](#) to the code for a debug exception, 0b00010, and [DFSR.Domain](#) to an UNKNOWN value.
- Long-descriptor format, the PE sets [DFSR.STATUS](#) to the code for a debug exception, 0b100010.

Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-20 on page G2-3974](#).
- Sets [DBGDSCRExt.MOE](#) to 0b1001, to indicate a Watchpoint exception.
- Sets the [HDFAR](#) to an address that the debugger can use to determine the memory location that triggered the watchpoint. See [Determining the memory location that caused a Watchpoint exception on page G2-3969](#).

Table G2-20 Information recorded in the HSR

| HSR field | Information recorded |
|------------------------------------|---|
| Exception Class, EC | The PE sets this to the code for a Data Abort exception routed to Hyp mode, 0x24. |
| Instruction Length, IL | The PE sets this to 1. |
| Instruction Specific Syndrome, ISS | <p>ISV[24] <i>Instruction Syndrome Valid (ISV)</i>. The PE sets this to 0.</p> <p>ISS[23:10] RES0.</p> <p>ISS[9] <i>External Abort type (EA)</i>. The PE sets this to 0.</p> <p>ISS[8] <i>Cache Maintenance (CM)</i>. The PE sets this to indicate whether a cache maintenance instruction caused the exception.</p> <p>ISS[7] RES0.</p> <p>ISS[6] <i>Write not Read (WnR)</i>. The PE sets this to indicate whether the exception was generated on a read instruction or a write instruction.</p> <p>ISS[5:0] <i>Data Fault Status Code (DFSC)</i>. The PE sets this to the code for a debug exception, 0b100010.</p> |

———— **Note** —————

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-3927](#).

Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

G2.10.9 Pseudocode description of Watchpoint exceptions taken from AArch32 state

`AArch32.WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch32.StateMatch()` tests the values in `DBGWCR<n>.{HMC, SSC, PAC}`, and if the watchpoint is Linked, also tests the Linked Context breakpoint that the watchpoint links to.

`AArch32.WatchpointMatch()` tests the value in `DBGWVR<n>`.

`AArch32.CheckWatchpoint()` generates a `FaultRecord`. A Watchpoint exception is taken if all of the following are true:

- `DBGDSCExt.MDBGen` is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See [Enabling debug exceptions from the current Privilege level and Security state on page G2-3929](#).
- All of the conditions required for Watchpoint exception generation are met. See [About Watchpoint exceptions on page G2-3961](#).

———— **Note** —————

`AArch32.CheckWatchpoint` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

The `AArch32.Abort()` function processes the `FaultRecord` object returned by `AArch32.CheckWatchpoint()`, as described in [Abort exceptions on page G3-4019](#). If a Watchpoint exception is taken to AArch32 state, the `AArch32.Abort()` function generates a Data Abort exception.

G2.11 Vector Catch exceptions

ARM deprecates the use of vector catch.

This section describes Vector Catch exceptions in stage 1 of an AArch32 translation regime.

The PE is using an AArch32 translation regime when it is executing either:

- At EL1 or higher in an Exception level that is using AArch32.
- At EL0 using AArch32 when EL1 is using AArch32.

Note

Vector Catch exceptions cannot be generated when the PE is using an AArch64 translation regime.

This section contains the following subsections:

- [About Vector Catch exceptions.](#)
- [Exception vectors that Vector Catch exceptions can be enabled for on page G2-3977.](#)
- [Generation of Vector Catch exceptions on page G2-3978.](#)
- [Usage constraints on page G2-3980.](#)
- [Exception syndrome information and preferred return address on page G2-3980.](#)
- [Pseudocode description of Vector Catch exceptions on page G2-3981.](#)

G2.11.1 About Vector Catch exceptions

Whenever the PE takes an exception, execution is forced to an address that is the *exception vector* for that exception. Vector catch permits a debugger to trap exceptions based on the exception vector, or based on the exception type associated with the exception vector, as follows:

- If the *address-matching* form of vector catch is implemented, the debugger can trap exceptions based on the exception vector.
- If the *exception-trapping* form of vector catch is implemented, the debugger can trap exceptions based on the exception type associated with the exception vector.

The ARMv8-A architecture supports only these two forms of vector catch. Only one form can be implemented, and which is implemented is IMPLEMENTATION DEFINED. The [DBGDEVID](#) indicates which form is implemented.

Regardless of the form of vector catch implemented, a debugger enables Vector Catch exceptions for exception vectors or types by programming the [DBGVCR](#). This register contains *vector catch enable bits*. Each of these bits corresponds to a different vector. When a debugger sets a vector catch enable bit to 1, Vector Catch exceptions are enabled for the corresponding exception vector or type.

Note

EL2 using AArch64 or EL3 using AArch64 can enable Vector Catch exceptions for vectors by programming the [DBGVCR32_EL2](#). The [DBGVCR32_EL2](#) is architecturally mapped to the [DBGVCR](#).

When Vector Catch exceptions are enabled for an exception vector, this is called an *enabled vector catch*. The set of exception vectors that Vector Catch exceptions are enabled for is called the *enabled vector catch set*.

If the form of vector catch implemented is the:

Address-matching form:

The PE compares the virtual address of each instruction in the program flow with a subset of the enabled vector catch set.

If an address match occurs, a Vector Catch exception is generated when the instruction that caused the match is committed for execution.

Exception-trapping form

Whenever the PE takes an exception, if the vector the exception is taken to is included in a subset of the enabled vector catch set, a Vector Catch exception is generated.

The Vector Catch exception is generated as part of entry to the exception, and must be taken before the PE either executes any instructions or takes any further exceptions.

The addresses that comprise the subset depend on whether EL3 is implemented and, for the:

- Address-matching form, the current Security state.
- Exception-trapping form, the Security state that the exception is handled in.

See [Generation of Vector Catch exceptions on page G2-3978](#).

[Table G2-21](#) summarizes the differences between the address-matching and exception-trapping forms.

Table G2-21 Differences in behavior of the address-matching and exception-trapping forms of vector catch

| Address-matching | Exception-trapping |
|--|--|
| <p>An enabled vector catch generates a Vector Catch exception when an instruction that is fetched from the vector is committed for execution.</p> <p>This means that spurious Vector Catch exceptions might occur, where the Vector Catch exception does not result from an exception entry, but is instead caused by a branch to the vector.</p> <p>A branch to the vector might occur, for example, on a return from a nested exception or when simulating an exception entry.</p> | <p>An enabled vector catch generates a Vector Catch exception immediately after the PE takes the exception that is associated with the vector.</p> <p>This means that Vector Catch exceptions always result from exception entry, and not from branches to exception vectors.</p> |
| <p>A Vector Catch exception is generated as a result of an instruction fetch. This means that the Vector Catch exception has a priority relative to the other synchronous exceptions that result from an instruction fetch.</p> <p>Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548 describes this prioritization.</p> | <p>A Vector Catch exception is generated as a result of an exception entry. This means that the Vector Catch exception is part of the exception that caused the Vector Catch exception. Therefore, the Vector Catch exception has no priority associated with it.</p> <p>For this reason, Vector Catch exceptions are outside the scope of the prioritization that Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548 describes.</p> |
| <p>A Vector Catch exception can be preempted by another exception. If this happens, the Vector Catch exception is generated again when the exception handler branches back to the vector.</p> | <p>Vector Catch exceptions must be taken before other exceptions.</p> |
| <p>A Vector Catch exception can be generated as a result of an instruction fetch executed in any AArch32 mode except Hyp mode, including User mode.</p> | <p>Because a Vector Catch exception is generated as the result of an exception entry, the Vector Catch exception is only generated when the PE is in the AArch32 exception handling mode.</p> |
| <p>If HCR.TGE is 1, Vector Catch exceptions can be generated for User mode instruction fetches from Non-secure PL1 vectors.</p> | <p>If HCR.TGE is 1, Vector Catch exceptions are never generated in Non-secure state, because:</p> <ul style="list-style-type: none"> • Exceptions are routed away from Non-secure PL1 vectors, to PL2. • The architecture does not provide vector catch enable bits for the Hyp exception vectors. |

Depending on the implementation, some vector catch enable bits in the **DBGVCR** might be RES0. For example, if EL3 is not implemented or is implemented but is using AArch64, Monitor mode is not implemented, and so the enable bits for exception vectors for exceptions taken to Monitor mode are RES0. See [Exception vectors that Vector Catch exceptions can be enabled for on page G2-3977](#) for the vector catch enable bits that exist for different implementations.

[The debug exception enable controls on page G2-3926](#) describes the enable controls for Vector Catch exceptions.

G2.11.2 Exception vectors that Vector Catch exceptions can be enabled for

When the PE takes an exception, the exception vector is contained in a *vector table* at the Privilege level the exception is taken to.

Depending on the Security state and AArch32 mode the exception is taken to, when the exception is taken, the vector table used is the table that contains one of:

- *Local exception vectors.*
- *Non-secure Local exception vectors.*
- *Secure Local exception vectors.*
- *Hyp exception vectors.*
- *Monitor exception vectors.*

Table G2-22 shows which vector tables are implemented for different implementations. In the table:

- A dash, -, means that the Exception level is not implemented.
- 64 means that the Exception level is using AArch64.
- 32 means that the Exception level is using AArch32.

Table G2-22 Vector tables implemented for different implementations

| Implementation | | | | Vector table or tables implemented |
|----------------|-----|-----|-----|--|
| EL0 | EL1 | EL2 | EL3 | |
| 32 | 32 | - | - | Local exception vectors. |
| | | 64 | - | Non-secure Local exception vectors. |
| | | 32 | - | Non-secure Local exception vectors. Hyp exception vectors. |
| | | - | 64 | Secure Local exception vectors. Non-secure Local exception vectors. |
| | | - | 32 | Secure Local exception vectors. Non-secure Local exception vectors. Monitor exception vectors. |
| | | 64 | 64 | Secure Local exception vectors. Non-secure Local exception vectors. |
| | | 32 | 64 | Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors. |
| | | 32 | 32 | Secure Local exception vectors. Non-secure Local exception vectors. Hyp exception vectors. Monitor exception vectors. |

For example, in an AArch32-only implementation that includes EL0, EL1, and EL3, when the PE takes an exception to Monitor mode, it uses the vector table containing Monitor exception vectors.

The tables that follow show the vectors that Vector Catch exceptions can be enabled for, and their corresponding vector catch enable bits in the **DBGVCR**:

- [Table G2-23](#) shows the Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for.
- [Table G2-24](#) shows the Monitor exception vectors that Vector Catch exceptions can be enabled for.

The ARMv8-A architecture does not provide vector catch enable bits for the Hyp exception vectors.

Table G2-23 Local exception vectors, Secure Local exception vectors, and Non-secure Local exception vectors that Vector Catch exceptions can be enabled for

| Vector catch enable bit | | Exception type | Local exception vectors | |
|---|------------------------------------|-----------------------|---|----------------------------|
| Local or Secure Local exception vectors | Non-secure Local exception vectors | | Normal. SCTLR.V is 0. ^a | High. SCTLR.V is 1. |
| SF | NSF | FIQ interrupt | VBAR + 0x0000001C | 0xFFFF001C |
| SI | NSI | IRQ interrupt | VBAR + 0x00000018 | 0xFFFF0018 |
| SD | NSD | Data Abort | VBAR + 0x00000010 | 0xFFFF0010 |
| SP | NSP | Prefetch Abort | VBAR + 0x0000000C | 0xFFFF000C |
| SS | NSS | Supervisor Call | VBAR + 0x00000008 | 0xFFFF0008 |
| SU | NSU | Undefined Instruction | VBAR + 0x00000004 | 0xFFFF0004 |

a. If EL3 is implemented and is using AArch32, **VBAR** is banked. The Secure Local exception vectors use **VBAR_S** and the Non-secure Local Exception vectors use **VBAR_{NS}**.

Table G2-24 Monitor exception vectors that Vector Catch exceptions can be enabled for

| Vector catch enable bit | Exception type | Monitor exception vectors |
|-------------------------|---------------------|---------------------------|
| MF | FIQ interrupt | MVBAR + 0x0000001C |
| MI | IRQ interrupt | MVBAR + 0x00000018 |
| MD | Data Abort | MVBAR + 0x00000010 |
| MP | Prefetch Abort | MVBAR + 0x0000000C |
| MS | Secure Monitor Call | MVBAR + 0x00000008 |

Note

There is no vector catch enable bit for Monitor trap exceptions.

G2.11.3 Generation of Vector Catch exceptions

How Vector Catch exceptions are generated depends on which form is implemented:

- [Address-matching form on page G2-3979.](#)
- [Exception-trapping form on page G2-3979.](#)

Address-matching form

The PE compares the virtual address of each instruction in the program flow is with some or all of the addresses in the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE compares the virtual address of each instruction in the program flow, including those executed at EL0, with all addresses in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
 - Monitor exception vectors, if EL3 is using AArch32.
 - Secure Local exception vectors.
 - Non-secure Local exception vectors.

In this case, [Table G2-25](#) shows which addresses, in the enabled vector catch set, the virtual address of each instruction in the program flow is compared with.

Table G2-25 Comparisons made if the implementation includes EL3

| EL3 is using | For exceptions taken to: | |
|--------------|--|------------------------------------|
| | Secure PL1 modes | Non-secure PL1 modes |
| AArch64 | Secure Local exception vectors | Non-secure Local exception vectors |
| AArch32 | Secure Local exception vectors and Monitor exception vectors | |

For example, for exceptions taken to a Secure PL1 mode when EL3 is using AArch64, the virtual address of each instruction in the program flow is compared with each Secure Local exception vector in the enabled vector catch set.

For each instruction in the program flow, the PE tests for any possible Vector Catch exceptions before executing the instruction. If a match occurs, a Vector Catch exception is generated when the instruction is committed for execution, regardless of all of the following:

- Whether the instruction passes its condition code check.
- Whether the instruction is executed as part of exception entry.
- If EL2 is implemented, what [HCR](#).{IMO, FMO, AMO} are set to.
- If EL3 is implemented, what [SCR](#).{IRQ, FIQ, EA} are set to.

Exception-trapping form

When the PE takes an exception, it tests whether the exception is by branching to an exception vector in a subset of the enabled vector catch set, as follows:

- If EL3 is not implemented, the enabled vector catch set contains only Local exception vectors. The PE tests whether the exception is by branching to any address in the enabled vector catch set.
- If EL3 is implemented, the enabled vector catch set might contain one or more of the following:
 - Monitor exception vectors, if EL3 is using AArch32.
 - Secure Local exception vectors.
 - Non-secure Local exception vectors.

In this case, the PE tests whether the exception is by branching to a vector in one of the subsets that [Table G2-26](#) shows. In the table, n/a means not applicable.

Table G2-26 Subsets that the PE tests within if EL3 is implemented

| EL3 is using | For exceptions taken to: | | |
|--------------|---------------------------|--------------------------------|------------------------------------|
| | Monitor mode | Other Secure PL1 modes | Non-secure PL1 modes |
| AArch64 | n/a | Secure Local exception vectors | Non-secure Local exception vectors |
| AArch32 | Monitor exception vectors | | |

For example, for an exception taken to a Secure PL1 mode when EL3 is using AArch64, the PE tests whether the exception is by branching to any of the Secure Local exception vectors in the enabled vector address set.

If the exception is by branching to a vector in the subset, a Vector Catch exception is generated as part of exception entry. That is, a Vector Catch exception is generated instead of the exception handler executing its first instruction.

G2.11.4 Usage constraints

See the following subsections:

- [Usage constraints that apply to both forms of vector catch.](#)
- [Usage constraints that apply only to the address-matching form.](#)

Usage constraints that apply to both forms of vector catch

For Vector Catch exceptions enabled for either the Prefetch Abort exception vector or the Data Abort exception vector, if one of these exception types is taken to the Exception level that debug exceptions are targeting, behavior is CONSTRAINED UNPREDICTABLE. Either:

- Vector catch is ignored, therefore a Vector Catch exception is not generated.
- Vector catch generates a Prefetch Abort debug exception. For Vector Catch exceptions enabled for the Prefetch Abort exception vector, the PE might enter a recursive loop of Prefetch Abort exceptions causing Vector Catch exceptions and Vector Catch exceptions causing Prefetch Abort exceptions.

———— Note —————

The Exception level that debug exceptions are targeting is called the *debug target Exception level*, EL_D . [Routing debug exceptions on page G2-3927](#) describes how EL_D is derived.

Usage constraints that apply only to the address-matching form

Exception vectors are at word-aligned addresses, and:

- It is CONSTRAINED UNPREDICTABLE whether an enabled vector catch generates a Vector Catch exception for a 32-bit T32 instruction starting at the halfword-aligned address immediately prior to the vector address.
- T32 instructions that start at the halfword-aligned address immediately after the exception vector do not generate Vector Catch exceptions.

For the address-matching form, Vector Catch exceptions have the same priority as Breakpoint exceptions. If a single instruction causes both a Vector Catch exception and a Breakpoint exception, it is CONSTRAINED UNPREDICTABLE which of these debug exceptions the PE takes.

G2.11.5 Exception syndrome information and preferred return address

See the following:

- [Exception syndrome information on page G2-3981.](#)

- [Preferred return address](#).

Exception syndrome information

The PE takes a Vector Catch exception as either:

- A Prefetch Abort exception if it is taken to PL1. In this case, it is taken to Abort mode.
- A Hyp trap exception, if it is taken to PL2 because [HCR.TGE](#) or [HDCR.TDE](#) is 1. In this case, it is taken to Hyp mode.

If the exception is taken to:

PL1 Abort mode

The PE sets all of the following:

- [IFSR.FS](#) to the code for a debug exception, `0b00010`.
- [DBGDSCRExt.MOE](#) to `0b0101`, to indicate a Vector Catch exception.
- The [IFAR](#) with an UNKNOWN value.

PL2 Hyp mode

The PE does all of the following:

- Records information about the exception in the *Hypervisor Syndrome Register*, [HSR](#). See [Table G2-27](#).
- Sets [DBGDSCRExt.MOE](#) to `0b0101`, to indicate a Vector Catch exception.
- Sets the [HIFAR](#) to an unknown value.

Table G2-27 Information recorded in the [HSR](#)

| HSR field | Information recorded |
|--|---|
| <i>Exception Class</i> , EC | The PE sets this to the code for a Prefetch Abort exception routed to Hyp mode, <code>0x20</code> . |
| <i>Instruction Length</i> , IL | The PE sets this to 1. |
| <i>Instruction Specific Syndrome</i> , ISS | ISS[24:10] RES0. ISS[9] <i>External Abort type</i> (EA). The PE sets this to 0. ISS[8:6] RES0. ISS[5:0] <i>Instruction Fault Status Code</i> (IFSC). The PE sets this to the code for a debug exception, <code>0b100010</code> . |

Note

For information about how debug exceptions can be routed to PL2, see [Routing debug exceptions on page G2-3927](#).

Preferred return address

The preferred return address of a Vector Catch exceptions is the address of the instruction that was not executed because the PE took the Vector Catch exception instead.

This means that the preferred return address is the exception vector. This is true regardless of whether the address-matching form or the exception trapping form is implemented.

G2.11.6 Pseudocode description of Vector Catch exceptions

The [AArch32.VCRMatch\(\)](#) pseudocode function checks whether the instruction at address generates a Vector Catch exception. It therefore shows the address-matching form of vector catch.

The `AArch32.CheckVectorCatch()` pseudocode function uses `AArch32.VCRMatch()` to test whether the instruction generates a Vector Catch exception, and if `AArch32.VCRMatch()` returns TRUE it generates that event.

The `AArch32.Abort()` function processes the Faultrecord object returned by `AArch32.CheckVectorCatch()`, as described in *Abort exceptions on page G3-4019*. If there is a Vector Catch exception, the `AArch32.Abort()` function generates a Prefetch Abort exception.

G2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
 - External debug registers.
 - System registers, including system debug registers.
 - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a *Context synchronization event* has occurred.

For any instructions executed between the time when the change is made and the time when the next *Context synchronization event* occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example G2-3

1. Software changes `DBGDSCRExt.MDBGGen` from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A *Context synchronization event* occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example G2-4

1. Software unlocks the OS lock.
2. The PE executes some instructions.
3. A *Context synchronization event* occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

- See *Context synchronization event* for the definition of this term.
 - Some register updates are self-synchronizing. Others require an explicit *Context synchronization event*. For more information, see both:
 - *Synchronization of changes to AArch32 System registers* on page G4-4163.
 - *Accessing PSTATE fields* on page G1-3806.
 - *Synchronization of changes to the external debug registers* on page H8-4964.
-

G2.12.1 State and mode changes without explicit context synchronization events

Most changes to the Exception level, and most changes to the Security state if EL3 is implemented, happen as a result of operations that are an explicit *Context synchronization event*. This is because taking an exception and returning from an exception are both explicit *Context synchronization events*, and the Privilege level and Security state can only change as a result of taking or returning from an exception.

However, some Security state and AArch32 mode changes can happen because of operations that are not an explicit *Context synchronization event*. These are:

- AArch32 mode changes caused by MSR and CPS instructions. A mode change might be to a mode at a lower Privilege level.
- If EL3 is using AArch32, a Security state change caused by a direct write to the SCR in a privileged mode other than Monitor mode, to set SCR.NS to 1.

Chapter G3

The AArch32 System Level Memory Model

This chapter provides a system level view of the general features of the memory system. It contains the following sections:

- *About the memory system architecture* on page G3-3986.
- *Address space* on page G3-3987.
- *Mixed-endian support* on page G3-3988.
- *AArch32 cache and branch predictor support* on page G3-3989.
- *System register support for IMPLEMENTATION DEFINED memory features* on page G3-4013.
- *External aborts* on page G3-4014.
- *Memory barrier instructions* on page G3-4016.
- *Pseudocode description of general memory system instructions* on page G3-4017.

G3.1 About the memory system architecture

The ARM architecture supports different implementation choices for the memory system microarchitecture and memory hierarchy, depending on the requirements of the system being implemented. In this respect, the memory system architecture describes a design space in which an implementation is made. The architecture does not prescribe a particular form for the memory systems. Key concepts are abstracted in a way that permits implementation choices to be made while enabling the development of common software routines that do not have to be specific to a particular microarchitectural form of the memory system. For more information about the concept of a hierarchical memory system see [Memory hierarchy on page E2-2318](#).

G3.1.1 Form of the memory system architecture

The ARMv8 A-profile architecture includes a *Virtual Memory System Architecture* (VMSA), described in [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

G3.1.2 Memory attributes

[Memory types and attributes on page E2-2342](#) describes the memory attributes, including how different memory types have different attributes. Each location in memory has a set of memory attributes, and the translation tables define the virtual memory locations, and the attributes for each location.

[Table G3-1](#) shows the memory attributes that are visible at the system level.

Table G3-1 Memory attribute summary

| Memory type | Shareability | Cacheability |
|---------------------|--|---|
| Device ^a | Outer Shareable | Non-cacheable. |
| Normal | One of: <ul style="list-style-type: none">Non-shareable.Inner Shareable.Outer Shareable. | One of ^b : <ul style="list-style-type: none">Non-cacheable.Write-Through Cacheable.Write-Back Cacheable. |

a. Takes additional attributes, see [Device memory on page E2-2346](#).

b. See also [Cacheability, cache allocation hints, and cache transient hints on page G3-3992](#).

For more information on Cacheability and Shareability see [The Cacheability and Shareability memory attributes on page E2-2319](#), [Non-shareable Normal memory on page E2-2344](#), and [Caches and memory hierarchy on page E2-2318](#).

G3.2 Address space

The ARMv8 architecture is designed to support a wide range of applications with different memory requirements. It supports a range of *physical address* (PA) sizes, and provides associated control and identification mechanisms. For more information, see [About VMSAv8-32 on page G4-4022](#).

G3.2.1 Address space overflow or underflow

This subsection describes address space overflow or underflow:

Instruction address space overflow

When a PE performs a normal, sequential execution of instructions, it calculates:

$$(\text{address_of_current_instruction}) + (\text{size_of_executed_instruction})$$

This calculation is performed after each instruction to determine which instruction to execute next.

If the address calculation performed after executing an A32 or T32 instruction overflows `0xFFFF FFFF`, the program counter becomes UNKNOWN.

If the PE executes an instruction for which the instruction address, size, and alignment mean that it contains the bytes `0xFFFFFFFF` and `0x00000000`, the bytes that apparently from `0x00000000` onwards come from an UNKNOWN address.

Data address space overflow and underflow

If the PE executes a load or store instruction for which the computed address, total access size, and alignment mean that it accesses bytes `0xFFFFFFFF` and `0x00000000`, then the bytes that apparently come from `0x00000000` onwards come from UNKNOWN addresses.

G3.3 Mixed-endian support

Table G3-2 shows the endianness of explicit data accesses and translation table walks.

Table G3-2 Endianness support

| Exception level | Explicit data accesses | Stage 1 translation table walks | Stage 2 translation table walks |
|-----------------|------------------------|---------------------------------|---------------------------------|
| EL0 | PSTATE.E | SCTLR(S/NS).EE | HSCTLR.EE |
| EL1 | PSTATE.E | SCTLR(S/NS).EE | HSCTLR.EE |
| EL2 | PSTATE.E | HSCTLR.EE | N/A |
| EL3 | PSTATE.E | SCTLR(S).EE | N/A |

ARMv8 provides the following options for endianness support:

- All Exception levels support mixed-endianness:
 - SCTLR(S/NS).EE, HSCTLR.EE, and PSTATE.E are RW.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only little-endianness:
 - SCTLR(S/NS).EE and HSCTLR.EE are RES0. PSTATE.E is RW when in EL0 and RES0 when in EL1, EL2, or EL3. SPSR.E is also RES0 when not returning to EL0.
- Only EL0 supports mixed-endianness and EL1, EL2, and EL3 support only big-endianness:
 - SCTLR(S/NS).EE and HSCTLR.EE are RES1. PSTATE.E is RW when in EL0 and RES1 when in EL1, EL2, or EL3. SPSR.E is also RES1 when not returning to EL0.
- All Exception levels support only little-endianness:
 - Each of SCTLR(S/NS).EE, HSCTLR.EE, PSTATE.E, and SPSR.E is RES0.
- All Exception levels support only big-endianness:
 - Each of SCTLR(S/NS).EE, HSCTLR.EE, PSTATE.E, and SPSR.E is RES1.

If mixed endian support is implemented for an Exception level using AArch32, endianness is controlled by PSTATE.E. For exception returns to AArch32 state, PSTATE.E is copied from SPSR_ELx.E. If the target Exception level supports only little-endian accesses, SPSR_ELx.E is RES0. If the target Exception level supports only big-endian accesses, SPSR_ELx.E is RES1.

———— **Note** —————

- When using AArch32, ARM deprecates PSTATE.E having a different value from the equivalent System register EE bit when in EL1, EL2 or EL3. The use of the SETEND instruction is also deprecated.
- If the higher Exception levels are using AArch64, the corresponding registers are:
 - SCTLR_EL1 for SCTLR(NS).
 - SCTLR_EL2 for HSCTLR.
 - SCTLR_EL3 for SCTLR(S).

The `BigEndian()` function determines whether the current Exception level and Execution state is using big-endian data.

G3.4 AArch32 cache and branch predictor support

The following sections describe the support for caches and branch predictors in AArch32 state:

- [General behavior of the caches.](#)
- [Cache identification on page G3-3991.](#)
- [Cacheability, cache allocation hints, and cache transient hints on page G3-3992.](#)
- [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-3993.](#)
- [Behavior of caches at reset on page G3-3995.](#)
- [AArch32 cache and branch predictor maintenance instructions on page G3-3999.](#)
- [About cache maintenance in ARMv8 on page G3-3995.](#)
- [AArch32 cache and branch predictor maintenance instructions on page G3-3999.](#)
- [Cache lockdown on page G3-4010.](#)
- [System level caches on page G3-4012.](#)

See also [Chapter G4 The AArch32 Virtual Memory System Architecture](#), and in particular [Caches in VMSAv8-32 on page G4-4106](#).

Note

- Branch predictors typically use a form of cache to hold branch target data. Therefore, they are included in this section.
- In the instruction mnemonics, MVA is a synonym for VA.

G3.4.1 General behavior of the caches

When a memory location is marked with a Normal Cacheable memory attribute, determining whether a copy of the memory location is held in a cache still depends on many aspects of the implementation. The following non-exhaustive list of factors might be involved:

- The size, line length, and associativity of the cache.
- The cache allocation algorithm.
- Activity by other elements of the system that can access the memory.
- Speculative instruction fetching algorithms.
- Speculative data fetching algorithms.
- Interrupt behaviors.

Given this range of factors, and the large variety of cache systems that might be implemented, the architecture cannot guarantee whether:

- A memory location present in the cache remains in the cache.
- A memory location not present in the cache is brought into the cache.

Instead, the following principles apply to the behavior of caches:

- The architecture has a concept of an entry locked down in the cache. How lockdown is achieved is IMPLEMENTATION DEFINED, and lockdown might not be supported by:
 - A particular implementation.
 - Some memory attributes.
- An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

- A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

———— **Note** —————

For more information, see [The interaction of cache lockdown with cache maintenance instructions on page G3-4010](#).

- Any memory location that has a Normal Cacheable attribute at either the current Exception level or at a higher Exception level can be allocated to a cache at any time.
- It is guaranteed that no memory location that does not have a Normal Cacheable attribute is allocated into the cache.
- It is guaranteed that no memory location is allocated to the cache if it has a Normal Non-cacheable attribute or any type of Device memory attribute in both:
 - The translation regime at the current Exception level.
 - The translation regime at any higher Exception level.
- For data accesses, any memory location with a Normal Inner Shareable or Normal Outer Shareable attribute is guaranteed to be coherent with all masters in its Shareability domain.
- Any memory location is not guaranteed to remain incoherent with the rest of memory.
- The eviction of a cache entry from a cache level can overwrite memory that has been written by another observer only if the entry contains a memory location that has been written to by an observer in the Shareability domain of that memory location. The maximum size of the memory that can be overwritten is called the *Cache Write-back Granule*. In some implementations the CTR identifies the Cache Write-back Granule, see [CTR, Cache Type Register on page G6-4293](#).
- The allocation of a memory location into a cache cannot cause the most recent value of that memory location to become invisible to an observer, if it was previously visible to that observer.

———— **Note** —————

The Cacheability attribute of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR.{I, C}](#) controls.

For the purpose of these principles, a cache entry covers at least 16 bytes and no more than 2KB of contiguous address space, aligned to the size of the cache entry.

G3.4.2 Cache identification

The ARMv8 cache identification consists of a set of registers that describe the implemented caches that are affected by cache maintenance instructions executed on the PE. This includes cache maintenance instructions that:

- Affect the entire cache, for example [ICIALLUIS](#).
- Operate by address, for example [ICIMVAU](#).
- Operate by set/way, for example [DCISW](#).

The cache identification registers are:

- A single Cache Type Register, [CTR](#), that defines:
 - The minimum line length of any of the instruction caches affected by the instruction cache maintenance instructions.
 - The minimum line length of any of the data or unified caches, affected by the data cache maintenance instructions.
 - The cache indexing and tagging policy of the Level 1 instruction cache.

———— **Note** ————

It is IMPLEMENTATION DEFINED whether caches beyond the PoC will be reported by this mechanism, and because of the possible existence of system caches some caches before the PoC might not be reported. For more information about system caches see [System level caches on page G3-4012](#).

- A single Cache Level ID Register, [CLIDR](#), that defines:
 - The type of cache that is implemented and can be maintained using the architected cache maintenance instructions that operate by set/way or operate on the entire cache at each cache level, up to the maximum of seven levels.
 - The *Level of Unification Inner Shareable (LoUIS)*, *Level of Coherence (LoC)* and the *Level of Unification (LoU)* for the caches. See [Terms used in describing the maintenance instructions on page G3-3996](#) for a definition of these terms.
 - An optional ICB field to indicate the boundary between the caches use for caching Inner Cacheable memory regions and those used only for caching Outer Cacheable regions.
- A single Cache Size Selection Register, [CSSELR](#), that selects the cache level and cache type of the current Cache Size Identification Register.
- For each implemented cache that is identifiable by this mechanism, across all the levels of caching, a Cache Size Identification Register, [CCSIDR](#), that defines:
 - Whether the cache supports Write-Through, Write-Back, Read-Allocate and Write-Allocate.
 - The number of sets, associativity and line length of the cache. See [Terms used in describing the maintenance instructions on page G3-3996](#) for a definition of these terms.

To determine the cache topology associated with a PE:

1. Read the Cache Type Register to find the indexing and tagging policy used for the Level 1 instruction cache. This register also provides the size of the smallest cache lines used for the instruction caches, and for the data and unified caches. These values are used in cache maintenance instructions.
2. Read the Cache Level ID Register to find what caches are implemented. The register includes seven Cache type fields, for cache levels 1 to 7. Scanning these fields, starting from Level 1, identifies the instruction, data or unified caches implemented at each level. This scan ends when it reaches a level at which no caches are defined. The Cache Level ID Register also specifies the Level of Unification (LoU) and the Level of Coherence (LoC) for the cache implementation.

3. For each cache identified at stage 2:
 - Write to the Cache Size Selection Register to select the required cache. A cache is identified by its level, and whether it is:
 - An instruction cache.
 - A data or unified cache.
 - Read the Cache Size ID Register to find details of the cache.

G3.4.3 Cacheability, cache allocation hints, and cache transient hints

Cacheability only applies to Normal memory, and is defined independently for Inner and Outer cache locations. All types of Device memory are always treated as Non-cacheable.

As described in [Memory types and attributes on page E2-2342](#), the memory attributes include a cacheability attribute that is one of:

- Non-cacheable.
- Write-Through cacheable.
- Write-Back cacheable.

In ARMv8, Cacheability attributes other than Non-cacheable can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. In addition, it is IMPLEMENTATION DEFINED whether a *cache transient hint* is supported, see [Transient cacheability hint](#).

The cache allocation hints are assigned independently for read and write accesses, and therefore when the Transient hit is supported the following cache allocation hints can be used:

For read accesses: Read-Allocate, Transient Read-Allocate, or No Read-Allocate.

For write accesses: Write-Allocate, Transient Write-Allocate, or No Write-Allocate.

———— Note —————

- A Cacheable location with both No Read-Allocate and No Write-Allocate hints is not the same as a Non-cacheable location. A Non-cacheable location has coherency guarantees for all observers within the system that do not apply for a location that is Cacheable, No Read-Allocate, No Write-Allocate.
- Implementations can use the cache allocation hints to limit cache pollution to a part of a cache, such as to a subset of ways.
- For VMSAv8-32 translation table walks using the Long-descriptor translation table format, the appropriate [TCR.{IRGN \$n\$, ORGN \$n\$ }](#) fields define the memory attributes of the translation tables, including the cacheability. However, this assignment supports only a subset of the cacheability attributes described in this section.

The architecture does not require an implementation to make any use of cache allocation hints. This means an implementation might not make any distinction between memory locations with attributes that differ only in their cache allocation hint.

Transient cacheability hint

In ARMv8, it is IMPLEMENTATION DEFINED whether a Transient hint is supported for the VMSAv8-32 translation scheme when using the Long-descriptor translation table format. In an implementation that supports the Transient hint, the Transient hint is a qualifier of the cache allocation hints, and indicates that the benefit of caching is for a relatively short period. It indicates that it might be better to restrict allocation of transient entries, to avoid possibly casting-out other, less transient, entries.

———— Note —————

The architecture does not specify what is meant by a *relatively short period*.

When using the Short-descriptor translation table format, VMSAv8-32 cannot support the Transient hint.

The description of the [MAIRO](#), [MAIR1](#), [HMAIRO](#), and [HMAIR1](#) registers includes the assignment of the Transient attribute in an implementation that supports this option. In this assignment:

- The Transient hint is defined independently for Inner Cacheable and Outer Cacheable memory regions.
- A single Transient hint applies to both read and write accesses to a memory region.

G3.4.4 Enabling and disabling the caching of memory accesses in AArch32 state

In ARMv8, Cacheability control fields can force all memory locations with the Normal memory type to be treated as Non-cacheable, regardless of their assigned Cacheability attribute. Independent controls are provided for each stage of address translation, with separate controls for:

- Data accesses. These controls also apply to accesses to the translation tables.
- Instruction accesses.

———— **Note** —————

These Cacheability controls replace the cache enable controls provided in previous versions of the ARM architecture.

In AArch32 state, the Cacheability control fields and their effects are as follows:

For the Non-secure PL1&0 translation regime

The Non-secure instance of [SCTLR](#) holds the EL1 controls that affect cacheability:

- When the value of [SCTLR.C](#) is 0:
 - All stage 1 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the PL1&0 stage 1 translation tables are Non-cacheable.
- When the value of [SCTLR.I](#) is 0:
 - All stage 1 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR2.CD](#) is 1:
 - All stage 2 translations for data accesses to Normal memory are Non-cacheable.
 - All accesses to the PL1&0 stage 2 translation tables are Non-cacheable.
- When the value of [HCR2.ID](#) is 1:
 - All stage 2 translations for instruction accesses to Normal memory are Non-cacheable.
- When the value of [HCR.DC](#) is 1, all Non-secure stage 1 translations and all accesses to the Non-secure EL1&0 stage 1 translation tables, are treated as accesses to Normal Non-shareable Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate memory, regardless of the value of [SCTLR.C](#). This applies to translations for both data and instruction accesses.

In addition, when the value of [SCTLR.M](#) is 0, indicating that the stage 1 translations are disabled for the translation regime, then if EL2 is using AArch32 and the value of [HCR.DC](#) is 0 or if EL2 is using AArch64 and the value of [HCR_EL2.DC](#) is 0, then:

- If the value of [SCTLR.I](#) is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of [SCTLR.I](#) is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

- In Non-secure state, the stage 1 and stage 2 cacheability attributes are combined as described in *Combining the Cacheability attribute on page G4-4087*.
 - The Non-secure **SCTLR**.{C, I} and **HCR**.DC fields have no effect on the Secure PL1&0 and EL2 translation regimes.
 - The **HCR2**.{ID, CD} fields affect only stage 2 of the Non-secure PL1&0 translation regime.
 - In Non-secure state, the PL1&0 translation regime can be described as the Non-secure EL1&0 translation regime. This is consistent with the equivalent AArch64 descriptions.
-

For the Secure PL1&0 translation regime

The Secure instance of **SCTLR** holds the controls that determine cacheability:

- When the value of **SCTLR**.C is 0:
 - All data accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.
 - All accesses to the Secure PL1&0 translation tables are Non-cacheable.
- When the value of **SCTLR**.I is 0:
 - All instruction accesses to Normal memory using the Secure PL1&0 translation regime are Non-cacheable.

In addition, when the value of **SCTLR**.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of **SCTLR**.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **SCTLR**.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

The Secure **SCTLR**.{I, C, M} fields have no effect on the Non-secure PL1&0 and EL2 translation regimes.

For the EL2 translation regime

- When the value of **HSCTLR**.C is 0:
 - All data accesses to Normal memory using the EL2 translation regime are Non-cacheable.
 - All accesses to the EL2 translation tables are Non-cacheable.
- When the value of **HSCTLR**.I is 0:
 - All instruction accesses to Normal memory using the EL2 translation regime are Non-cacheable.

In addition, when the value of **HSCTLR**.M is 0, indicating that stage 1 translations are disabled, then:

- If the value of **HSCTLR**.I is 0, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Non-cacheable, Outer Non-cacheable.
- If the value of **HSCTLR**.I is 1, instruction accesses to Normal memory from stage 1 of the translation regime are Outer Shareable, Inner Write-Through cacheable, Outer Write-Through cacheable.

Note

The **HSCTLR**.{I, C, M} fields have no effect on the PL1&0 and EL3 translation regimes.

The effect of the **SCTLR**.C or **HSCTLR**.C and **HCR2**.CD bits is reflected in the result of the address translation instructions in the PAR.

Note

- The requirements in this section mean the architecturally required effects of [SCTLR.I](#) and [HSCTLR.I](#) are limited to their effects on caching instruction accesses in unified caches.
- This specification can give rise to different cacheability attributes between instruction and data accesses to the same location. Where this occurs, the measures for mismatch memory attributes described in [Mismatched memory attributes on page E2-2352](#) must be followed to manage the corresponding loss of coherency.

G3.4.5 Behavior of caches at reset

In ARMv8:

- All caches reset to IMPLEMENTATION DEFINED states that might be UNKNOWN.
- The Cacheability control fields described in [Enabling and disabling the caching of memory accesses in AArch32 state on page G3-3993](#) reset to values that force all memory locations to be treated as Non-cacheable.

Note

This applies only to the controls that apply to the Translation regime that is used by the Exception level, PE mode, and Security state entered on reset.

- An implementation can require the use of a specific cache initialization routine to invalidate its storage array before caching is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, and the routine must be documented clearly as part of the documentation of the device.
- If an implementation permits cache hits when the Cacheability control fields force all memory locations to be treated as Non-cacheable then the cache initialization routine must:
 - Provide a mechanism to ensure the correct initialization of the caches.
 - Be documented clearly as part of the documentation of the device.In particular, if an implementation permits cache hits when the Cacheability controls force all memory locations to be treated as Non-cacheable, and the cache contents are not invalidated at reset, the initialization routine must avoid any possibility of running from an uninitialized cache. It is acceptable for an initialization routine to require a fixed instruction sequence to be placed in a restricted range of memory.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 cache maintenance instructions.

Similar rules apply to:

- Branch predictor behavior, see [Behavior of the branch predictors at reset on page G3-4003](#).
- TLB behavior, see [TLB behavior at reset on page G4-4090](#).

G3.4.6 About cache maintenance in ARMv8

The following sections give general information about the ARMv8 cache maintenance:

- [Terms used in describing the maintenance instructions on page G3-3996](#).
- [The ARMv8 abstraction of the cache hierarchy on page G3-3999](#).

The following sections describe the AArch32 state cache maintenance instructions for ARMv8:

- [AArch32 instruction cache maintenance instructions \(IC*\) on page G3-4001](#).
- [AArch32 data cache maintenance instructions \(DC*\) on page G3-4001](#).

Note

Some descriptions of the cache maintenance instructions refer to the cacheability of the address on which the instruction operates. The Cacheability of an address is determined by the applicable translation table entry for that address, as modified by any applicable System register Cacheability controls, such as the [SCTLR.{I, C}](#) controls.

Terms used in describing the maintenance instructions

Cache maintenance instructions are defined to act on particular memory locations. Instructions can be defined:

- By the address of the memory location to be maintained, referred to as operating *by VA*.
- By a mechanism that describes the location in the hardware of the cache, referred to as operating *by set/way*.

In addition, for instruction caches and branch predictors, there are instructions that invalidate all entries.

The following subsections define the terms used in the descriptions of the cache maintenance instructions:

- [Terminology for cache maintenance instruction operating by virtual address, VA](#).
- [Terminology for cache maintenance instructions operating by set/way](#).
- [Terminology for Clean, Invalidate, and Clean and Invalidate instructions on page G3-3997](#).

Terminology for cache maintenance instruction operating by virtual address, VA

In a VMSA implementation, the addresses used by the PE are VAs. When all applicable stages of translation are disabled, the VA is identical to the PA.

———— Note ————

For more information about memory system behavior when address translation is disabled, see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4031](#).

For the cache maintenance instruction, any instruction described as operating by VA includes as part of any required VA to PA translation:

- For an instruction executed at EL1, the current system *Address Space Identifier*, ASID.
- The current Security state.
- Whether the instruction was performed from Hyp mode, or from Non-secure EL1 state.
- For an instruction executed from a Non-secure EL1 state, the *Virtual Machine Identifier*, VMID.

For a data or unified cache maintenance instruction by VA, the operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault cases described in:

- [Data cache maintenance instructions \(DC*\) on page D3-1704](#).
- [Stage 2 fault on a stage 1 translation table walk on page G4-4117](#).

For an instruction cache maintenance instruction by VA:

- It is IMPLEMENTATION DEFINED whether the operation can generate a Data Abort exception for a Translation fault or an Access flag fault.
- The operation cannot generate a Data Abort exception for a Domain fault or a Permission fault, except for the Permission fault case described in [Stage 2 fault on a stage 1 translation table walk on page G4-4117](#).

For more information about these faults, see [MMU faults in AArch32 state on page G4-4118](#).

Terminology for cache maintenance instructions operating by set/way

Cache maintenance instruction that operate by set/way refer to the particular structures in a cache. Three parameters describe the location in a cache hierarchy that an instruction works on. These parameters are:

Level The cache level of the hierarchy. The number of levels of cache is IMPLEMENTATION DEFINED. The cache levels that can be managed using the architected cache maintenance instructions that operate by set/way can be determined from the [CLIDR](#).

In the ARM architecture, the lower numbered cache levels are those closest to the PE. See [Memory hierarchy on page E2-2318](#).

Set Each level of a cache is split up into a number of *sets*. Each set is a set of locations in a cache level to which an address can be assigned. Usually, the set number is an IMPLEMENTATION DEFINED function of an address.

In the ARM architecture, sets are numbered from 0.

Way The associativity of a cache is the number of locations in a set to which a specific address can be assigned. The *way* number specifies one of these locations.
In the ARM architecture, ways are numbered from 0.

———— **Note** —————

Because the allocation of a memory address to a cache location is entirely IMPLEMENTATION DEFINED, ARM expects that most portable software will use only the cache maintenance instructions by set/way as single steps in a routine to perform maintenance on the entire cache.

Terminology for Clean, Invalidate, and Clean and Invalidate instructions

Caches introduce coherency problems in two possible directions:

1. An update to a memory location by a PE that accesses a cache might not be visible to other observers that can access memory. This can occur because new updates are still in the cache and are not visible yet to the other observers that do not access that cache.
2. Updates to memory locations by other observers that can access memory might not be visible to a PE that accesses a cache. This can occur when the cache contains an old, or *stale*, copy of the memory location that has been updated.

The *Clean* and *Invalidate* instructions address these two issues. The definitions of these instructions are:

Clean A cache clean instruction ensures that updates made by an observer that controls the cache are made visible to other observers that can access memory at the point to which the instruction is performed. Once the Clean has completed, the new memory values are guaranteed to be visible to the point to which the instruction is performed, for example to the Point of Unification.

The cleaning of a cache entry from a cache can overwrite memory that has been written by another observer only if the entry contains a location that has been written to by an observer in the Shareability domain of that memory location.

Invalidate A cache invalidate instruction ensures that updates made visible by observers that access memory at the point to which the invalidate is defined, are made visible to an observer that controls the cache. This might result in the loss of updates to the locations affected by the invalidate instruction that have been written by observers that access the cache, if those updates have not been cleaned from the cache since they were made.

If the address of an entry on which the invalidate instruction operates is Normal, Non-cacheable or any type of Device memory then an invalidate instruction also ensures that this address is not present in the cache.

———— **Note** —————

Entries for addresses that are Normal Cacheable can be allocated to the cache at any time, and so the cache invalidate instruction cannot ensure that the address is not present in a cache.

Clean and Invalidate

A cache *clean and invalidate* instruction behaves as the execution of a clean instruction followed immediately by an invalidate instruction. Both instructions are performed to the same location.

The points to which a cache maintenance instruction can be defined differ depending on whether the instruction operates by VA or by set/way:

- For instructions operating by set/way, the point is defined to be to the next level of caching. For the All operations, the point is defined as the Point of Unification for each location held in the cache.

- For instruction operating by VA, two conceptual points are defined:

Point of Coherency (PoC)

For a particular VA, the PoC is the point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases, this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherence between memory system agents.

———— **Note** ————

The presence of system caches can affect the definition of the point of coherency as described in [System level caches on page G3-4012](#).

Point of Unification (PoU)

The PoU for a PE is the point by which the instruction and data caches and the translation table walks of that PE are guaranteed to see the same copy of a memory location. In many cases, the Point of Unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged.

The PoU for an Inner Shareable Shareability domain is the point by which the instruction and data caches and the translation table walks of all the PEs in that Inner Shareable Shareability domain are guaranteed to see the same copy of a memory location. Defining this point permits self-modifying software to ensure future instruction fetches are associated with the modified version of the software by using the standard correctness policy of:

1. Clean data cache entry by address.
2. Invalidate instruction cache entry by address.

The following fields in the [CLIDR](#) relate to these conceptual points:

LoC, Level of Coherence

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Coherency. The LoC value is a cache level, so, for example, if LoC contains the value 3:

- A clean to the Point of Coherency operation requires the level 1, level 2 and level 3 caches to be cleaned.
- Level 4 cache is the first level that does not have to be maintained.

If the LoC field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Coherency.

If the LoC field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Coherency.

LoUU, Level of Unification, uniprocessor

This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the PE. As with LoC, the LoUU value is a cache level.

If the LoUU field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification.

If the LoUU field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

LoUIS, Level of Unification, Inner Shareable

In any implementation:

- This field defines the last level of cache that must be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain. As with LoC, the LoUIS value is a cache level.
- If the LoUIS field value is $0x0$, this means that no levels of cache need to be cleaned or invalidated when cleaning or invalidating to the Point of Unification for the Inner Shareable Shareability domain.
- If the LoUIS field value is a nonzero value that corresponds to a level that is not implemented, this indicates that all implemented caches are before the Point of Unification.

For more information, see [CLIDR, Cache Level ID Register on page G6-4274](#).

The ARMv8 abstraction of the cache hierarchy

The following subsections describe the ARMv8 abstraction of the cache hierarchy:

- [Cache maintenance instructions that operate by address](#).
- [Cache maintenance instructions that operate by set/way](#).

Cache maintenance instructions that operate by address

The address-based cache maintenance instructions are described as operating by VA. Each of these instructions is always qualified as being either:

- Performed to the Point of Coherency.
- Performed to the Point of Unification.

See [Terms used in describing the maintenance instructions on page G3-3996](#) for definitions of Point of Coherency and Point of Unification, and more information about possible meanings of VA.

[AArch32 cache and branch predictor maintenance instructions](#) lists the address-based maintenance instructions.

The **CTR** holds minimum line length values for:

- The instruction caches.
- The data and unified caches.

These values support efficient invalidation of a range of addresses, because this value is the most efficient address stride to use to apply a sequence of address-based maintenance instructions to a range of addresses.

For the Invalidate data or unified cache line by VA instruction, the Cache Write-back Granule field of the **CTR** defines the maximum granule that a single invalidate instruction can invalidate. This meaning of the Cache Write-back Granule is in addition to its defining the maximum size that can be written back.

Cache maintenance instructions that operate by set/way

[AArch32 cache and branch predictor maintenance instructions](#) lists the set/way-based maintenance instructions. Some encodings of these instructions include a required field that specifies the cache level for the instruction:

- A clean instruction cleans from the level of cache specified through to at least the next level of cache, moving further from the PE.
- An invalidate instruction invalidates only at the level specified.

G3.4.7 AArch32 cache and branch predictor maintenance instructions

The instruction and data cache maintenance instructions have the same functionality in AArch32 state and in AArch64 state. [Table G3-3 on page G3-4000](#) shows these system instructions. Instructions that take an argument include Rt in the instruction description.

AArch32 state also provides branch predictor maintenance instructions.

———— Note —————

- In [Table G3-3 on page G3-4000](#) the Point of Unification is the Point of Unification of the PE executing the cache maintenance instruction.
- In AArch32 state, all of the maintenance instructions are available from EL1 or higher.
- In AArch64 state, branch predictors are always invisible to software, and therefore AArch64 state does not provide any branch predictor maintenance instructions.

Table G3-3 AArch32 System instructions for cache maintenance

| Register | Instruction |
|--|--|
| Instruction cache maintenance instructions | |
| ICIALLUIS | Invalidate all to Point of Unification, Inner Shareable |
| ICIALLU | Invalidate all to Point of Unification |
| ICIMVAU, Rt | Invalidate by virtual address to Point of Unification |
| Data cache maintenance instructions | |
| DCIMVAC, Rt | Invalidate by virtual address to Point of Coherency |
| DCISW, Rt | Invalidate by set/way |
| DCCMVAC, Rt | Clean by virtual address to Point of Coherency |
| DCCSW, Rt | Clean by set/way |
| DCCMVAU, Rt | Clean by virtual address to Point of Unification |
| DCCIMVAC, Rt | Clean and invalidate by virtual address to Point of Coherency |
| DCCISW, Rt | Clean and invalidate by set/way |
| Branch prediction maintenance instructions | |
| BPIMVA, Rt | Invalidate the virtual address from the branch predictors |
| BPIALLIS, Rt | Invalidate all entries from branch predictors, Inner Shareable |
| BPIALL, Rt | Invalidate all entries from branch predictors |

A DSB or DMB instruction intended to ensure the completion of cache or branch predictor maintenance instructions must have an access type of both loads and stores.

In an implementation where the branch predictors are architecturally invisible, the [BPIMVA](#), [BPIALLIS](#), and [BPIALL](#) instructions can execute as NOPs.

The following subsections give more information about these instructions:

- [AArch32 instruction cache maintenance instructions \(IC*\)](#) on page G3-4001.
- [AArch32 data cache maintenance instructions \(DC*\)](#) on page G3-4001.
- [Branch predictors](#) on page G3-4002.
- [General requirements for the scope of cache and branch predictor maintenance instructions](#) on page G3-4003.
- [Effects of instructions that operate by virtual address to the Point of Coherency](#) on page G3-4004.
- [Effects of instructions that operate by virtual address but not to the Point of Coherency](#) on page G3-4004.
- [Effects of All and set/way maintenance instructions](#) on page G3-4005.
- [Effects of virtualization and security on the AArch32 cache maintenance instructions](#) on page G3-4005.
- [Boundary conditions for cache maintenance instructions](#) on page G3-4007.
- [Ordering of cache and branch predictor maintenance instructions](#) on page G3-4007.

- [Performing cache maintenance instructions on page G3-4009](#).

AArch32 instruction cache maintenance instructions (IC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

All instruction cache maintenance instructions can execute in any order relative to other instruction cache maintenance instructions, data cache maintenance instructions, and loads and stores, unless a DSB is executed between the instructions.

An instruction cache maintenance instruction can complete at any time after it is executed, but is only guaranteed to be complete, and its effects visible to other observers, following a DSB instruction executed by the PE that executed the cache maintenance instruction.

See also [Ordering of cache and branch predictor maintenance instructions on page G3-4007](#).

AArch32 data cache maintenance instructions (DC*)

Where an address argument for these instructions is required, it takes the form of a 32-bit register that holds the virtual address argument. No alignment restrictions apply for this address.

Data cache maintenance instructions that take a set/way/level argument take a 32-bit register.

A data or unified cache invalidation by virtual address instruction performed in a Non-secure EL1 mode must not change data in any location for which the stage 2 translation permissions do not permit write access. Where such a permission violation occurs, it is IMPLEMENTATION DEFINED whether:

- A stage 2 Permission fault is generated for the [DCIMVAC](#) operation.
- The [DCIMVAC](#) operation is upgraded to [DCCIMVAC](#).

[DCIMVAC](#) and [DCISW](#) at EL1 is performed by the PE as clean and invalidate, that is [DCCIMVAC](#) or [DCCISW](#) if all of the following apply:

- EL2 is implemented.
- PL1&0 stage two address translation is enabled, meaning either:
 - EL2 is using AArch32 and the value of [HCR.VM](#) is 1.
 - EL2 is using AArch64 and the value of [HCR_EL2.VM](#) is 1.
- EL3 is not implemented, or either:
 - EL3 is using AArch32 and the value of [SCR.NS](#) is 1.
 - EL3 is using AArch64 and the value of [SCR_EL3.NS](#) is 1.

————— **Note** —————

Similarly, [DCIMVAC](#) and [DCISW](#) at EL1 must be performed as clean and invalidate, that is [DCCIMVAC](#) and [DCCISW](#) at EL1 when EL1 is using AArch32, if all of the following apply:

- EL2 is implemented.
- EL2 is using AArch32 and [HCR.VM](#) is set to the value of 1, or EL2 is using AArch64 and [HCR_EL2.VM](#) is set to the value of 1.
- EL3 is using AArch32 and [SCR.NS](#) is set to the value of 1, or EL3 is using AArch64 and [SCR.NS](#) is set to the value of 1, or EL3 is not implemented.

If a data cache maintenance by set/way instruction specifies a set, way, or level argument that is larger than the value supported by the implementation then the instruction is CONSTRAINED UNPREDICTABLE, see [Out of range values of the Set/Way/Index fields in cache maintenance instructions on page K1-5467](#) or the instruction description.

If a memory fault that sets FAR for the translation regime applicable for the cache maintenance instruction is generated from a data cache maintenance instruction, the FAR holds the address specified in the register argument of the instruction.

See also [Ordering of cache and branch predictor maintenance instructions](#) on page G3-4007.

Branch predictors

In AArch32 state it is IMPLEMENTATION DEFINED whether branch prediction is architecturally visible. This means that under some circumstances software must perform branch predictor maintenance to avoid incorrect execution caused by out-of-date entries in the branch predictor. For example, to ensure correct operation it might be necessary to invalidate branch predictor entries on a change to instruction memory, or a change of instruction address mapping. For more information, see [Specific requirements for branch predictor maintenance instructions](#).

In an implementation where the branch predictors are architecturally invisible, the branch predictor maintenance instructions can execute as NOPs.

An invalidate all operation on the branch predictor ensures that any location held in the branch predictor has no functional effect on execution. An invalidate branch predictor by VA instruction operates on the address of the branch instruction, but can affect other branch predictor entries.

———— Note —————

The architecture does not make visible the range of addresses in a branch predictor to which the invalidate operation applies. This means the address used in the invalidate by VA operation must be the address of the branch to be invalidated.

If branch prediction is architecturally visible, an instruction cache invalidate all operation also invalidates all branch predictors.

See also [Ordering of cache and branch predictor maintenance instructions](#) on page G3-4007.

Specific requirements for branch predictor maintenance instructions

If, for a given translation regime and a given ASID and VMID as appropriate, the instructions at any virtual address change, then branch predictor maintenance instructions must be performed to invalidate entries in the branch predictor, to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.
- For the Non-secure PL1&0 translation regime:
 - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
 - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
 - Enabling or disabling stage 2 translations.
- Writing new mappings to the translation tables.
- Any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers, unless:
 - For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
 - For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.
- Any change to the [VTTBR](#) or [VTCR](#) registers, unless accompanied by a change to the VMID.

Note

Invalidation is not required if the changes to the translations are such that the instructions associated with the non-faulting translations of a virtual address, for a given translation regime and a given ASID and VMID, as appropriate, remain unchanged throughout the sequence of changes to the translations. Examples of translation changes to which this applies are:

- Changing a valid translation to a translation that generates an MMU fault.
 - Changing a translation that generates an MMU fault to a valid translation.
-

Failure to invalidate entries might give CONSTRAINED UNPREDICTABLE results, caused by the execution of old branches. For more information, see [Ordering of cache and branch predictor maintenance instructions on page G3-4007](#).

Note

- In ARMv8, there is no requirement to use the branch predictor maintenance operations to invalidate the branch predictor after:
 - Changing the ContextID or VMID.
 - A cache maintenance instruction that is identified as also flushing the branch predictors, see [AArch32 cache and branch predictor maintenance instructions on page G3-3999](#).
-

[Cache maintenance instructions, functional group on page G4-4201](#) shows the branch predictor maintenance operations in a VMSA implementation.

Behavior of the branch predictors at reset

In ARMv8:

- If branch predictors are not architecturally invisible:
 - The branch predictors reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
 - The branch predictors are disabled at reset.
- An implementation can require the use of a specific branch predictor initialization routine to invalidate the branch predictor storage array before it is enabled. The exact form of any required initialization routine is IMPLEMENTATION DEFINED, but the routine must be documented clearly as part of the documentation of the device.
- ARM recommends that whenever an invalidation routine is required, it is based on the ARMv8 branch predictor maintenance operations.

Similar rules apply:

- To cache behavior, see [Behavior of caches at reset on page G3-3995](#).
- To TLB behavior, see [TLB behavior at reset on page G4-4090](#).

General requirements for the scope of cache and branch predictor maintenance instructions

The ARMv8 specification of the cache maintenance and branch predictor instructions describes what each instruction is guaranteed to do in a system. It does not limit other behaviors that might occur, provided they are consistent with the requirements described in [General behavior of the caches on page G3-3989](#), [Behavior of caches at reset on page G3-3995](#), and [Preloading caches on page E2-2321](#).

This means that as a side-effect of a cache maintenance instruction:

- Any location in the cache might be cleaned.
- Any unlocked location in the cache might be cleaned and invalidated.

As a side-effect of a branch predictor maintenance instruction, any entry in the branch predictor might be invalidated.

———— **Note** ————

ARM recommends that, for best performance, such side-effects are kept to a minimum. ARM strongly recommends that the side-effects of operations performed in Non-secure state do not have a significant performance impact on execution in Secure state.

Effects of instructions that operate by virtual address to the Point of Coherency

For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of other PEs in the Shareability domain described by the Shareability attributes of the VA supplied with the instruction.

For Device memory and Normal memory that is Inner Non-cacheable, Outer Non-cacheable, these instructions must affect the caches of all PEs in the Outer Shareable Shareability domain of the PE on which the instruction is operating.

In all cases, for any affected PE, these instructions affect all data and unified caches to the Point of Coherency.

Table G3-4 PEs affected by cache maintenance instructions to the Point of Coherency

| Shareability | PEs affected | Effective to |
|-----------------|--|---|
| Non-shareable | The PE performing the operation | The Point of Coherency of the entire system |
| Inner Shareable | All PEs in the same Inner Shareable Shareability domain as the PE performing the operation | The Point of Coherency of the entire system |
| Outer Shareable | All PEs in the same Outer Shareable Shareability domain as the PE performing the operation | The Point of Coherency of the entire system |

Effects of instructions that operate by virtual address but not to the Point of Coherency

The following instruction operate by virtual address but not to the Point of Coherency:

- Clean data or unified cache line by MVA to the Point of Unification, [DCCMVAU](#).
- Invalidate instruction cache line by MVA to Point of Unification, [ICIMVAU](#).
- Invalidate by MVA from branch predictors, [BPIMVA](#).

For these instructions, [Table G3-5](#) shows how, for a VA in a Normal or Device memory location, the Shareability attribute of the VA determines the minimum set of PEs affected, and the point to which the instruction must be effective.

Table G3-5 PEs affected by cache maintenance instructions to the Point of Unification

| Shareability | PEs affected | Effective to |
|------------------------------------|---|--|
| Non-shareable | The PE executing the instruction | The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, on the PE executing the instruction |
| Inner Shareable or Outer Shareable | All PEs in the same Inner Shareable Shareability domain as the PE executing the instruction | The Point of Unification of instruction cache fills, data cache fills and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain as the PE executing the instruction |

———— **Note** ————

The set of PEs guaranteed to be affected is never greater than the PEs in the Inner Shareable Shareability domain containing the PE executing the instruction.

Effects of All and set/way maintenance instructions

The [ICIALLU](#), [BPIALL](#) and DC* set/way instructions apply only to the caches and branch predictors of the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLU](#) also performs a [BPIALL](#) operation.

The [ICIALLUIS](#) and [BPIALLIS](#) instructions can affect the caches and branch predictors of all PEs in the same Inner Shareable Shareability domain as the PE that performs the instruction. If the branch predictors are architecturally-visible, [ICIALLUIS](#) also performs a [BPIALLIS](#) operation. These instructions have an effect to the Point of Unification of instruction cache fills, data cache fills, and write-backs, and translation table walks, of all PEs in the same Inner Shareable Shareability domain.

———— Note —————

The possible presence of system caches, as described in [System level caches on page G3-4012](#), means architecture does not guarantee that all levels of cache can be maintained using set/way instructions.

Effects of virtualization and security on the AArch32 cache maintenance instructions

Each Security state has its own physical address space, and therefore cache entries are associated with physical address space. In addition, cache maintenance and branch predictor instructions performed in Non-secure state have to take account of:

- Whether the instruction was performed at EL1 or at EL2.
- For instructions that operate by VA, the current VMID.

[Table G3-6](#) shows the effects of virtualization and security on these maintenance instructions.

Table G3-6 Effects of virtualization and security on the AArch32 cache maintenance instructions

| Cache maintenance instructions | Security state | Specified entry |
|--|----------------|--|
| Data or unified cache maintenance instructions | | |
| Invalidate, Clean, or Clean and Invalidate by VA: DCIMVAC , DCCMVAC , DCCMVAU , DCCIMVAC | Either | All lines that hold the PA that, in the current translation regime, are mapped to by the combination of all of: <ul style="list-style-type: none"> • The specified VA. • For an instruction executed at EL1, the current ASID if the location is mapped to by a non-global page. • For an instruction executed at Non-secure EL1, the current VMID^a. |
| | Non-secure | Line specified by set/way provided that the entry comes from the Non-secure PA space. |
| Invalidate, Clean, or Clean and Invalidate by set/way: DCISW , DCCSW , DCCISW | Secure | Line specified by set/way regardless of the PA space that the entry has come from. |

Table G3-6 Effects of virtualization and security on the AArch32 cache maintenance instructions (continued)

| Cache maintenance instructions | Security state | Specified entry |
|---|----------------|---|
| Instruction cache maintenance instructions | | |
| Invalidate by VA: ICIMVAU | Either | All lines corresponding to the specified VA ^b in the current translation regime and: <ul style="list-style-type: none"> For an instruction executed at EL1 or EL0, the current ASID. For an instruction executed at Non-secure EL1 or Non-secure EL0, the current VMID^a. |
| Invalidate All: ICIALLU , ICIALUIS | | <ul style="list-style-type: none"> Can invalidate any unlocked entry in the instruction cache. Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information: <p>Non-secure</p> <p>An instruction executed at EL1 must operate on all instruction cache lines that contain entries associated with the current virtual machine, meaning any entry with the current VMID.^a</p> <p>An instruction executed at EL2 must operate on all instruction cache lines that contain entries that can be accessed from Non-secure state.</p> <p>Secure</p> <p>The instruction must invalidate all instruction cache lines.</p> |
| Branch predictor instructions ^c | | |
| Invalidate by VA: BPIMVA | Either | All lines that, in the current translation regime, are mapped to by the combination of: all of: <ul style="list-style-type: none"> The specified VA. For an instruction executed at EL1 or EL0, the current ASID if the location is mapped to by a non-global page. For an instruction executed at Non-secure EL1 or EL0, the current VMID^a. |
| Invalidate all: BPIALL , BPIALLIS | | <ul style="list-style-type: none"> Can invalidate any unlocked entry in the branch predictor. Are required to invalidate any entries relevant to the software component that executed it. The Non-secure and Secure descriptions give more information. |

a. Dependencies on the VMID apply even when [HCR_EL2.VM](#) is set to 0. However, [VTTBR_EL2.VMID](#) resets to zero, meaning there is a valid VMID from reset.

b. The type of instruction cache used affects the interpretation of the specified entries in this table such that:

- For a PIPT instruction cache, the cache maintenance applies to all entries whose physical address corresponds to the specified address.
- For a VIPT instruction cache, the cache maintenance applies to entries whose virtual index and physical tag corresponds to the specified address.
- For an ASID and VMID tagged VIVT instruction cache, the cache maintenance applies to entries whose virtual address corresponds to the specified address.

For information of types of instruction cache, see [Instruction caches on page G4-4106](#).

c. In an implementation where the branch predictors are architecturally invisible, these instructions can execute as NOPs.

For locked entries and entries that might be locked, the behavior of cache maintenance instructions described in [The interaction of cache lockdown with cache maintenance instructions on page G3-4010](#) applies.

With an implementation that generates aborts if entries are locked or might be locked in the cache, when the use of lockdown aborts is enabled, these aborts can occur on any cache maintenance instructions.

In an implementation that includes EL2:

- The architecture does not require cache cleaning when switching between virtual machines. Cache invalidation by set/way must not present an opportunity for one virtual machine to corrupt state associated with a second virtual machine. To ensure this requirement is met, Non-secure clean by set/way operations can be upgraded to clean and invalidate by set/way.

- The AArch32 Data cache invalidate instructions **DCIMVAC** and **DCISW**, perform a cache clean as well as a cache invalidate, meaning they operate as **DCCIMVAC** and **DCCISW** respectively, if both of the following apply:
 - The value of **HCR.VM** is 1.
 - The instruction is executed in Non-secure state, or EL3 is not implemented.
- The AArch32 Data cache invalidate by set/way instruction **DCISW** performs a cache clean as well as a cache invalidate, meaning it operates as **DCCISW**, if both of the following apply:
 - The value of **HCR.SWIO** is 1.
 - The instruction is executed in Non-secure state, or EL3 is not implemented.
- When the value of **HCR.FB** is 1, TLB and instruction cache invalidate instructions executed in the Non-secure EL1 Exception level are broadcast across the Inner Shareable domain. When Non-secure EL1 is using AArch32, this applies to the **TLBIMVA**, **TLBIASID**, **TLBIMVAA**, **TLBIMVAL**, **TLBIMVAAL**, and **ICIALLU** instructions. This means the instruction is upgraded to the corresponding Inner Shareable instruction, for example **ICIALLU** is upgraded to **ICIALLUIS**, and **BPIALL** is upgraded to **BPIALLIS**.

For more information about the cache maintenance instructions, see [About cache maintenance in ARMv8 on page G3-3995](#), [AArch32 cache and branch predictor maintenance instructions on page G3-3999](#), and [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

Boundary conditions for cache maintenance instructions

Cache maintenance instructions operate on the caches regardless of whether the System register Cacheability controls force all memory accesses to be Non-cacheable.

For address-based cache maintenance instructions, the instructions operate on the caches regardless of the memory type and cacheability attributes marked for the memory address in the VMSA translation table entries. This means that the effects of the cache maintenance instructions can apply regardless of:

- Whether the address accessed:
 - Is Normal memory or Device memory.
 - Has the Cacheable attribute or the Non-cacheable attribute.
- Any applicable domain control of the address accessed.
- The access permissions for the address accessed, other than the effect of the stage two write permission on data or unified cache invalidation instructions.

Ordering of cache and branch predictor maintenance instructions

The following rules describe the effect of the memory order model on the cache and branch predictor maintenance instructions:

- All cache and branch predictor maintenance instructions that do not specify an address execute, relative to each other, in program order.
All cache and branch predictor instructions that specify an address:
 - Execute in program order relative to all cache and branch predictor operations that do not specify an address.
 - Execute in program order relative to all cache and branch predictor operations that specify the same address.
 - Can execute in any order relative to cache and branch predictor operations that specify a different address.
- Where a cache maintenance or branch predictor instruction appears in program order before a change to the translation tables, the architecture guarantees that the cache or branch predictor maintenance instruction uses the translations that were visible before the change to the translation tables.

- Where a change of the translation tables appears in program order before a cache maintenance or branch predictor instruction, software must execute the sequence outlined in [Ordering and completion of TLB maintenance instructions on page G4-4096](#) before performing the cache or branch predictor maintenance instruction, to ensure that the maintenance operation uses the new translations.
- A DMB instruction causes the effect of all data or unified cache maintenance instructions appearing in program order before the DMB to be visible to all explicit load and store operations appearing in program order after the DMB.

Also, a DMB instruction ensures that the effects of any data or unified cache maintenance instruction appearing in program order before the DMB are observable by any observer in the same required Shareability domain before any data or unified cache maintenance or explicit memory operations appearing in program order after the DMB are observed by the same observer. Completion of the DMB does not guarantee the visibility of all data to other observers. For example, all data might not be visible to a translation table walk, or to instruction fetches.
- A DSB is required to guarantee the completion of all cache maintenance instruction that appear in program order before the DSB instruction.
- A [Context synchronization event](#) is required to guarantee the effects of any branch predictor maintenance operation. This means a [Context synchronization event](#) causes the effect of all completed branch predictor maintenance operations appearing in program order before the [Context synchronization event](#) to be visible to all instructions after the [Context synchronization event](#).

———— **Note** —————

See [Context synchronization event](#) in the [Glossary](#) for the definition of this term.

This means that, if a branch instruction appears after an invalidate branch predictor operation and before any [Context synchronization event](#), it is CONSTRAINED UNPREDICTABLE whether the branch instruction is affected by the invalidate. Software must avoid this ordering of instructions, because it might cause CONSTRAINED UNPREDICTABLE behavior.

- Any data or unified cache maintenance instruction by VA must be executed in program order relative to any explicit load or store on the same PE to an address covered by the VA of the cache instruction if that load or store is to Normal Cacheable memory. The order of memory accesses that result from the cache maintenance instruction, relative to any other memory accesses to Normal Cacheable memory, are subject to the memory ordering rules. For more information, see [Memory ordering on page E2-2332](#).

Any data or unified cache maintenance instruction by VA can be executed in any order relative to any explicit load or store on the same PE to an address covered by the VA of the cache maintenance instruction if that load or store is not to Normal Cacheable memory.
- There is no restriction on the ordering of data or unified cache maintenance instruction by VA relative to any explicit load or store on the same PE where the address of the explicit load or store is not covered by the VA of the cache instruction. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- There is no restriction on the ordering of a data or unified cache maintenance instruction by set/way relative to any explicit load or store on the same PE. Where the ordering must be restricted, a DMB instruction must be inserted to enforce ordering.
- Software must execute a [Context synchronization event](#) after the completion of an instruction cache maintenance instruction, to guarantee that the effect of the maintenance instruction is visible to any instruction fetch.

A DSB or DMB instruction intended to ensure the completion of cache maintenance instructions or branch predictor instructions must have an access type of both loads and stores.

The scope of instruction cache maintenance depends on the type of the instruction cache. For more information see [Instruction caches on page G4-4106](#).

Example G3-1 Cache cleaning operations for self-modifying code

The sequence of cache cleaning operations for a line of self-modifying code on a uniprocessor system is:

```

; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first line
; instead of STR for a 16-bit instruction.
STR Rt, [Rn]
DCCMVAU Rn      ; Clean data cache by MVA to point of unification (PoU)
DSB             ; Ensure visibility of the data cleaned from cache
ICIMVAU Rn     ; Invalidate instruction cache by MVA to PoU
BPIMVA Rn      ; Invalidate branch predictor by MVA to PoU
DSB            ; Ensure completion of the invalidations
ISB            ; Synchronize the fetched instruction stream

```

Performing cache maintenance instructions

To ensure all cache lines in a block of address space are maintained through all levels of cache ARM strongly recommends that software:

- For data or unified cache maintenance, uses the **CTR.DMinLine** value to determine the loop increment size for a loop of data cache maintenance by VA instructions.
- For instruction cache maintenance, uses the **CTR.IMinLine** value to determine the loop increment size for a loop of instruction cache maintenance by VA instructions.

Example code for cache maintenance instructions

The cache maintenance instructions by set/way can be used to clean or invalidate, or both, the entirety of one or more levels of cache attached to a PE. However, unless all PEs attached to the caches regard all memory locations as Non-cacheable, it is not possible to prevent locations being allocated into the cache during such a sequence of the cache maintenance instructions.

———— Note —————

Because the set/way instructions operate only locally, there is no guarantee of the atomicity of cache maintenance between different PEs, even if those different PEs are each executing the same cache maintenance instructions at the same time. Because any cacheable line can be allocated into the cache at any time, it is possible for a cache line to migrate from an entry in the cache of one PE to the cache of a different PE in a way that means the cache line is not affected by set/way based cache maintenance. Therefore, ARM strongly discourages the use of set/way instructions to manage coherency in coherent systems. The expected use of the cache maintenance instructions that operate by set/way is limited to the cache maintenance associated with the powerdown and powerup of caches, if this is required by the implementation.

The limitations of cache maintenance by set/way mean maintenance by set/way does not happen on multiple PEs, and cannot be made to happen atomically for each address on each PE. Therefore in multiprocessor or multithreaded systems, the use of cache maintenance by set/way to clean, or clean and invalidate, the entire cache for coherency management with very large buffers or with buffers with unknown address can fail to provide the expected coherency results because of speculation by other PEs, or possibly by other threads. The only way that these instructions can be used in this way is to first ensure that all PEs that might cause speculative accesses to caches that need to be maintained are not capable of generating speculative accesses. This can be achieved by ensuring that those PEs have no memory locations with a Normal Cacheable attribute. Such an approach can have very large system performance effects, and ARM advises implementers to use hardware coherency mechanisms in systems where this will be an issue.

[System level caches on page G3-4012](#) refers to other limitations of cache maintenance by set/way.

The following example code for cleaning a data or unified cache to the Point of Coherency illustrates a generic mechanism for cleaning the entire data or unified cache to the Point of Coherency.

```

    MRC p15, 1, R0, c0, c0, 1 ; Read CLIDR into R0
    ANDS R3, R0, #0x07000000
    MOV R3, R3, LSR #23 ; Cache level value (naturally aligned)
    BEQ Finished
    MOV R10, #0
Loop1
    ADD R2, R10, R10, LSR #1 ; Work out 3 x cache level
    MOV R1, R0, LSR R2 ; bottom 3 bits are the Cache type for this level
    AND R1, R1, #7 ; get those 3 bits alone
    CMP R1, #2
    BLT Skip ; no cache or only instruction cache at this level
    MCR p15, 2, R10, c0, c0, 0 ; write CSSELR from R10
    ISB ; ISB to sync the change to the CCSIDR
    MRC p15, 1, R1, c0, c0, 0 ; read current CCSIDR to R1
    AND R2, R1, #7 ; extract the line length field
    ADD R2, R2, #4 ; add 4 for the line length offset (log2 16 bytes)
    MOV R4, #0x3FF
    ANDS R4, R4, R1, LSR #3 ; R4 is the max number on the way size (right aligned)
    CLZ R5, R4 ; R5 is the bit position of the way size increment
    MOV R9, R4 ; R9 working copy of the max way size (right aligned)
Loop2
    MOV R7, #0x00007FFF
    ANDS R7, R7, R1, LSR #13 ; R7 is the max number of the index size (right aligned)
Loop3
    ORR R11, R10, R9, LSL R5 ; factor in the way number and cache number into R11
    ORR R11, R11, R7, LSL R2 ; factor in the index number
    MCR p15, 0, R11, c7, c10, 2 ; DCCSW, clean by set/way
    SUBS R7, R7, #1 ; decrement the index
    BGE Loop3
    SUBS R9, R9, #1 ; decrement the way number
    BGE Loop2
Skip
    ADD R10, R10, #2 ; increment the cache number
    CMP R3, R10
    DSB ; ensure completion of previous cache maintenance instruction
    BGT Loop1
Finished
  
```

Similar approaches can be used for all cache maintenance instructions.

G3.4.8 Cache lockdown

The concept of an entry locked in a cache is allowed, but not architecturally defined. How lockdown is achieved is IMPLEMENTATION DEFINED and might not be supported by:

- An implementation.
- Some memory attributes.

An unlocked entry in a cache might not remain in that cache. The architecture does not guarantee that an unlocked cache entry remains in the cache or remains incoherent with the rest of memory. Software must not assume that an unlocked item that remains in the cache remains dirty.

A locked entry in a cache is guaranteed to remain in that cache. The architecture does not guarantee that a locked cache entry remains incoherent with the rest of memory, that is, it might not remain dirty.

The interaction of cache lockdown with cache maintenance instructions

The interaction of cache lockdown and cache maintenance instructions is IMPLEMENTATION DEFINED. However, an architecturally-defined cache maintenance instruction on a locked cache line must comply with the following general rules:

- The effect of the following instructions on locked cache entries is IMPLEMENTATION DEFINED:
 - Cache clean by set/way, [DCCSW](#).

- Cache invalidate by set/way, [DCISW](#).
- Cache clean and invalidate by set/way, [DCISW](#).
- Instruction cache invalidate all, [ICIALLU](#) and [ICIALLUIS](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is not invalidated from the cache.
2. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [Data Abort exception on page G1-3859](#).

This permits a usage model for cache invalidate routines to operate on a large range of addresses by performing the required operation on the entire cache, without having to consider whether any cache entries are locked.

The effect of the following instructions is IMPLEMENTATION DEFINED:

- Cache clean by virtual address, [DCCMVAC](#) and [DCCMVAU](#).
- Cache invalidate by virtual address, [DCIMVAC](#).
- Cache clean and invalidate by virtual address, [DCCIMVAC](#).

However, one of the following approaches must be adopted in all these cases:

1. If the instruction specified an invalidation, a locked entry is invalidated from the cache. For the clean and invalidate instructions, the entry must be cleaned before it is invalidated.
2. If the instruction specified an invalidation, a locked entry is not invalidated from the cache. If the instruction specified a clean it is IMPLEMENTATION DEFINED whether locked entries are cleaned.
3. If an entry is locked down, or could be locked down, an IMPLEMENTATION DEFINED Data Abort exception is generated, using the fault status code defined for this purpose. See [DFSR](#) or [HSR](#).

In an implementation that includes EL2, if [HCR.TIDCP](#) is set to 1, any exception relating to lockdown of an entry associated with Non-secure memory is routed to EL2.

———— **Note** ————

An implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required operations on entries that are not locked down.
- Implement one of the other permitted alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use architecturally-defined instructions. This minimizes the number of customized instructions required.

In addition, an implementation that uses an abort to handle cache maintenance instructions for entries that might be locked must provide a mechanism that ensures that no entries are locked in the cache.

The reset setting of the cache must be that no cache entries are locked.

Additional cache functions for the implementation of lockdown

An implementation can add additional cache maintenance functions for the handling of lockdown in the IMPLEMENTATION DEFINED space. See [IMPLEMENTATION DEFINED registers, functional group on page G4-4211](#).

G3.4.9 System level caches

The system level architecture might define further aspects of the software view of caches and the memory model that are not defined by the ARMv8 architecture. These aspects of the system level architecture can affect the requirements for software management of caches and coherency. For example, a system design might introduce additional levels of caching that cannot be managed using the architecturally-defined maintenance instructions. Such caches are referred to as *system caches*.

Conceptually, three classes of system cache can be envisaged:

1. System caches which lie before the point of coherency and cannot be managed by cache maintenance instructions. Such systems fundamentally undermine the concept of cache maintenance instructions operating to the point of coherency, as they imply the use of non-architecture mechanisms to manage coherency. The use of such systems in the ARM architecture is explicitly prohibited.
2. System caches which lie before the point of coherency and can be managed by cache maintenance by address instructions that apply to the point of coherency, but cannot be managed by cache maintenance by set/way instructions. Where maintenance of the entire system cache must be performed, as is the case for power management, it must be performed using non-architectural mechanisms.
3. System caches which lie beyond the point of coherency and so are invisible to software. The management of such caches is outside the scope of architecture.

G3.5 System register support for IMPLEMENTATION DEFINED memory features

The VMSAv8-32 defines the following registers for describing IMPLEMENTATION DEFINED features of the memory system:

- The TCM Type Register, [TCMTR](#) must be implemented. The following conditions apply to this register:
 - If no TCMs are implemented, the [TCMTR](#) indicates zero-size TCMs.
 - If bits[31:29] are 0b100, the format of the rest of the register is IMPLEMENTATION DEFINED. This value indicates that the implementation includes TCMs that do not follow the legacy usage model. Other fields in the register might give more information about the TCMs.
- The System register encoding space with {coproc==0b1111, CRn==c9, CRm=={c0-c2, c5-c7}} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for branch predictor, cache and TCM functionality, for example maintenance, override behaviors and lockdown.
- In a VMSAv8-32 implementation, part of the System register encoding space with {coproc==0b1111, CRn==c10} is IMPLEMENTATION DEFINED and reserved for TLB functionality, see [TLB lockdown on page G4-4091](#).
- The System register encoding space with {coproc==0b1111, CRn==c11, CRm=={c0-c8, c15}} is IMPLEMENTATION DEFINED for all values of opc2 and opc1. This space is reserved for DMA operations to and from the TCMs.

In addition, the System register encoding space with {coproc==0b1111, CRn==c15} is reserved for IMPLEMENTATION DEFINED registers, and can provide additional registers for the memory system. For more information, see [Reserved encodings in the VMSAv8-32 System register \(coproc==0b1111\) space on page G4-4177](#).

G3.6 External aborts

The ARM architecture defines external aborts as errors that occur in the memory system, other than those that are detected by the MMU or Debug hardware. External aborts include parity or ECC errors detected by the caches or other parts of the memory system. For example, an uncorrectable parity or ECC failure on a Level 2 Memory structure might generate an external abort.

An external abort is one of:

- Synchronous.
- Precise asynchronous.
- Imprecise asynchronous.

For more information, see [Exception terminology on page G1-3784](#).

The ARM architecture does not provide any method to distinguish between precise asynchronous and imprecise asynchronous external aborts.

VMSAv8-32 permits external aborts on data accesses, translation table walks, and instruction fetches to be either synchronous or asynchronous. The reported fault code identifies whether the external abort is synchronous or asynchronous.

It is IMPLEMENTATION DEFINED which external aborts, if any, are supported. Asynchronous external aborts are taken as SError interrupt exceptions.

In AArch32 state:

- SError interrupts are taken as asynchronous Data Abort exceptions.
- Synchronous external aborts:
 - On data accesses are taken as synchronous Data Abort exceptions.
 - On instruction fetches, or prefetches, are taken as synchronous Prefetch Abort exceptions.

See also:

- [External abort on a translation table walk on page G4-4120](#).
- [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#).

Normally, external aborts are rare. An imprecise asynchronous external abort is likely to be fatal to the process that is running. ARM recommends that implementations make external aborts precise wherever possible.

The following subsections give more information about possible external aborts:

- [External abort on instruction fetch](#).
- [External abort on data read or write](#).
- [Provision for classification of external aborts on page G3-4015](#).
- [Parity or ECC error reporting on page G3-4015](#).

The section [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#) describes the reporting of external aborts.

G3.6.1 External abort on instruction fetch

An external abort on an instruction fetch can be either synchronous or asynchronous. A synchronous external abort on an instruction fetch is taken precisely.

An implementation can report the external abort asynchronously from the instruction that it applies to. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when `PSTATE.A` is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.2 External abort on data read or write

Externally-generated errors during a data read or write can be either synchronous or asynchronous.

An implementation can report the external abort asynchronously from the instruction that generated the access. In such an implementation these aborts behave essentially as interrupts. The aborts are masked when `PSTATE.A` is set to 1, otherwise they are reported using the Data Abort exception.

G3.6.3 Provision for classification of external aborts

For a synchronous external abort taken to a privileged mode other than Hyp mode, an implementation can use the `DFSR.ExT` and `IFSR.ExT` bits to provide more information about synchronous external aborts:

- `DFSR.ExT` provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on data accesses.
- `IFSR.ExT` provides an IMPLEMENTATION DEFINED classification of synchronous external aborts on instruction accesses.

For a synchronous external abort taken to Hyp mode, the `HSR.EA`, `ISS[9]` bit, provides an IMPLEMENTATION DEFINED classification of external aborts.

For all aborts other than synchronous external aborts these bits return a value of 0.

G3.6.4 Parity or ECC error reporting

The ARM architecture supports the reporting of both synchronous and asynchronous parity or ECC errors from the cache systems. It is IMPLEMENTATION DEFINED what parity or ECC errors in the cache systems, if any, result in synchronous or asynchronous parity or ECC errors.

A fault code is defined for reporting parity or ECC errors, see [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#). However when parity or ECC error reporting is implemented it is IMPLEMENTATION DEFINED whether a parity or ECC error is reported using the assigned fault code, or using another appropriate encoding.

For all purposes other than the fault status encoding, parity or ECC errors are treated as external aborts.

G3.7 Memory barrier instructions

[Memory barriers on page E2-2335](#) describes the memory barrier instructions. This section describes the system level controls of those instructions.

G3.7.1 EL2 control of the Shareability of data barrier instructions executed at EL0 or EL1

In an implementation that includes EL2 and supports Shareability limitations on the data barrier instructions, the [HCR.BSU](#) field can upgrade the required Shareability of an instruction that is executed at EL0 or EL1 in Non-secure state. [Table G3-7](#) shows the encoding of this field:

Table G3-7 EL2 control of Shareability of barrier instructions executed at EL0 or EL1

| HCR.BSU | Minimum Shareability of barrier instructions |
|-------------------------|--|
| 00 | No effect, Shareability is as specified by the instruction |
| 01 | Inner Shareable |
| 10 | Outer Shareable |
| 11 | Full system |

For an instruction executed at EL0 or EL1 in Non-secure state, [Table G3-8](#) shows how the [HCR.BSU](#) is combined with the Shareability specified by the argument of the DMB or DSB instruction to give the scope of the instruction:

Table G3-8 Effect of the [HCR_EL2.BSU](#) on barrier instructions executed at Non-secure EL1 or EL1

| Shareability specified by the DMB or DSB argument | HCR.BSU | Resultant Shareability |
|---|-------------------------|------------------------|
| Full system | Any | Full system |
| | 00, 01, or 10 | Outer Shareable |
| Outer Shareable | 11, Full system | Full system |
| | 00 or 01 | Inner Shareable |
| | 10, Outer Shareable | Outer Shareable |
| Inner Shareable | 11, Full system | Full system |
| | 00, No effect | Non-shareable |
| | 01, Inner Shareable | Inner Shareable |
| Non-shareable | 10, Outer Shareable | Outer Shareable |
| | 11, Full system | Full system |
| | 11, Full system | Full system |

G3.8 Pseudocode description of general memory system instructions

This section lists the pseudocode describing general memory operations:

- [Memory data type definitions](#).
- [Basic memory access](#).
- [Aligned memory access](#) on page G3-4018.
- [Unaligned memory access](#) on page G3-4018.
- [Exclusive monitors operations](#) on page G3-4018.
- [Access permission checking](#) on page G3-4019.
- [Abort exceptions](#) on page G3-4019.
- [Memory barriers](#) on page G3-4019.

G3.8.1 Memory data type definitions

This section lists the memory data types.

The memory data types are:

- Address descriptor, defined by the [AddressDescriptor](#) type.
- Full address, defined by the [FullAddress](#) type.
- Memory attributes, defined by the [MemoryAttributes](#) type.
- Memory type, defined by the [MemType](#) enumeration.
- Device memory type, defined by the [DeviceType](#) enumeration.
- Normal memory attributes, defined by the [MemAttrHints](#) type.
- Cacheability attributes, defined by the [MemAttr_NC](#), [MemAttr_WT](#), and [MemAttr_WB](#) constants.
- Allocation hints, defined by the [MemHint_No](#), [MemHint_WA](#), [MemHint_RA](#), and [MemHint_RWA](#) constants.
- Access permissions, defined by the [Permissions](#) type.

G3.8.2 Basic memory access

The two `_Mem[]` accessors, Non-assignment (memory read) `_Mem[]` and Assignment (memory write) `_Mem[]`, are the operations that perform single-copy atomic, aligned, little-endian memory accesses of size bytes to or from the underlying physical memory array of bytes.

The functions address the array using `desc.paddress` which supplies:

- A 48-bit physical address.
- A single NS bit to select between Secure and Non-secure parts of the array.

The `AccType` parameter describes the access type, such as normal, exclusive, ordered, and streaming. For a definition of `AccType`, see [Address space](#) on page E2-2316.

The actual implemented array of memory might be smaller than the 2^{48} bytes implied. In this case the scheme for aliasing is IMPLEMENTATION DEFINED, or some parts of the address space might give rise to external aborts or a System Error.

The attributes in `memaddrdesc.memattrs` are used by the memory system to determine caching and ordering behaviors as described in [Memory types and attributes](#) on page E2-2342, [Memory ordering](#) on page E2-2332, and [Atomicity in the ARM architecture](#) on page E2-2328.

`PAMax()` returns the IMPLEMENTATION DEFINED size of the physical address.

———— Note —————

A translation regime used when the PE is executing in AArch32 state can never generate more than 40 bits of an address.

G3.8.3 Aligned memory access

The `AArch32.MemSingle[]` functions make atomic, little-endian accesses of size bytes.

G3.8.4 Unaligned memory access

See *Unaligned data access* on page E2-2323 for details of the `SCTLR.A` and `HSCTLR.A` controls on the generation of alignment faults. The `HSCTLR` control applies to Normal memory accesses from Hyp mode, and the `SCTLR` control applies to Normal memory accesses from all other modes.

The `Mem_with_type[]` functions make an access of the required type. If that access is naturally aligned, each form of the function performs an atomic access by making a single call to `AArch32.MemSingle[]`. If that access is not aligned but passes the `AArch32.CheckAlignment()` checks, each form of the function synthesizes the required access from multiple calls to `AArch32.MemSingle[]`. It also reverses the byte order if the access is big-endian.

G3.8.5 Exclusive monitors operations

The `AArch32.SetExclusiveMonitors()` function sets the exclusive monitors for a Load-Exclusive instruction, for a block of bytes. The size of the blocks is determined by `size`, at the VA address. The `ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors and therefore completes successfully.

The `AArch32.ExclusiveMonitorsPass()` function checks whether a Store-Exclusive instruction still has possession of the exclusive monitors, by checking whether the exclusive monitors are set to include the location of the memory block specified by `size`, at the virtual address defined by `address`. The atomic write that follows after the exclusive monitors have been set must be to the same physical address. It is permitted, but not required, for this function to return `FALSE` if the virtual address is not the same as that used in the previous call to `AArch32.SetExclusiveMonitors()`.

The `ExclusiveMonitorsStatus()` function returns 0 if the previous atomic write was to the same physical memory locations selected by `ExclusiveMonitorsPass()` and therefore succeeded. Otherwise the function returns 1, indicating that the address translation delivered a different physical address.

The `MarkExclusiveGlobal()` procedure takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The procedure records that the PE `processorid` has requested exclusive access covering at least `size` bytes from address `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, up to a limit of 2KB and no smaller than two words, and aligned in the address space to the size of the location. It is CONstrained UNPREDICTABLE whether this causes any previous request for exclusive access to any other address by the same PE to be cleared.

The `MarkExclusiveLocal()` procedure takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The procedure records in a local record that PE `processorid` has requested exclusive access to an address covering at least `size` bytes from address `address`. The size of the location marked as exclusive is IMPLEMENTATION DEFINED, and can at its largest cover the whole of memory but is no smaller than two words, and is aligned in the address space to the size of the location. It is IMPLEMENTATION DEFINED whether this procedure also performs a `MarkExclusiveGlobal()` using the same parameters.

The `IsExclusiveGlobal()` function takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked in a global record an address range as exclusive access requested that covers at least `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether it returns `TRUE` or `FALSE` if a global record has marked a different address as exclusive access requested. If no address is marked in a global record as exclusive access, `IsExclusiveGlobal()` returns `FALSE`.

The `IsExclusiveLocal()` function takes as arguments a `FullAddress.address`, the PE identifier `processorid` and the size of the transfer. The function returns `TRUE` if the PE `processorid` has marked an address range as exclusive access requested that covers at least the `size` bytes from address `address`. It is IMPLEMENTATION DEFINED whether this function returns `TRUE` or `FALSE` if the address marked as exclusive access requested does not cover all of `size` bytes from address `address`. If no address is marked as exclusive access requested, then this function returns `FALSE`. It is IMPLEMENTATION DEFINED whether this result is ANDed with the result of `IsExclusiveGlobal()` with the same parameters.

The `ClearExclusiveByAddress()` procedure takes as arguments a `FullAddress` address, the PE identifier `processorid` and the size of the transfer. The procedure clears the global records of all PEs, other than `processorid`, for which an address region including any of `size` bytes starting from `paddress` has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether the equivalent global record of the PE `processorid` is also cleared if any of `size` bytes starting from `paddress` has had a request for an exclusive access, or if any other address has had a request for an exclusive access.

The `ClearExclusiveLocal()` procedure takes as arguments the PE identifier `processorid`. The procedure clears the local record of PE `processorid` for which an address has had a request for an exclusive access. It is IMPLEMENTATION DEFINED whether this operation also clears the global record of PE `processorid` that an address has had a request for an exclusive access.

G3.8.6 Access permission checking

The function `AArch32.CheckPermission()` is used by the architecture to perform access permission checking based on attributes derived from the translation tables or location descriptors.

The interpretation of access permission is shown in *Memory access control* on page G4-4068.

G3.8.7 Abort exceptions

The function `AArch32.Abort()` generates a Data Abort exception or a Prefetch Abort exception by calling the `AArch32.TakeDataAbortException()` or `AArch32.TakePrefetchAbortException()` function.

The `FaultRecord` type describes a fault. Functions that check for faults return a record of this type appropriate to the type of fault. *Pseudocode description of VMSAv8-32 memory system operations* on page G4-4215 provides a number of wrappers to generate a `FaultRecord`.

The function `AArch32.NoFault()` returns a null record that indicates no fault. The `IsFault()` function tests whether a `FaultRecord` contains a fault.

G3.8.8 Memory barriers

The definition for the memory barrier functions is given by the enumerations `MBReqDomain` and `MBReqTypes`.

These enumerations define the required Shareability domains and required access types used as arguments for DMB and DSB instructions.

The procedures `DataMemoryBarrier()`, `DataSynchronizationBarrier()`, and `InstructionSynchronizationBarrier()` perform the memory barriers.

Chapter G4

The AArch32 Virtual Memory System Architecture

This chapter describes the ARMv8-A AArch32 Virtual Memory System Architecture (VMSA), that is backwards-compatible with VMSAv7. It includes the following sections:

- *About VMSAv8-32 on page G4-4022.*
- *The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4031.*
- *Translation tables on page G4-4035.*
- *The VMSAv8-32 Short-descriptor translation table format on page G4-4040.*
- *The VMSAv8-32 Long-descriptor translation table format on page G4-4049.*
- *Memory access control on page G4-4068.*
- *Memory region attributes on page G4-4077.*
- *Translation Lookaside Buffers (TLBs) on page G4-4089.*
- *TLB maintenance requirements on page G4-4093.*
- *Caches in VMSAv8-32 on page G4-4106.*
- *VMSAv8-32 memory aborts on page G4-4110.*
- *Exception reporting in a VMSAv8-32 implementation on page G4-4123.*
- *Address translation instructions on page G4-4142.*
- *About the System registers for VMSAv8-32 on page G4-4148.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1110) encoding space on page G4-4172.*
- *VMSAv8-32 organization of registers in the (coproc == 0b1111) encoding space on page G4-4175.*
- *Functional grouping of VMSAv8-32 System registers on page G4-4193.*
- *Pseudocode description of VMSAv8-32 memory system operations on page G4-4215.*

Note

This chapter must be read with [Chapter G3 The AArch32 System Level Memory Model](#).

G4.1 About VMSAv8-32

———— **Note** ————

- This chapter describes the ARMv8 VMSA for AArch32 state, VMSAv8-32. This is generally equivalent to VMSAv7 for an implementation that includes all of the Security Extensions, the Multiprocessing Extensions, the Large Physical Address Extension, and the Virtualization Extensions.
- This chapter describes the control of the VMSA by Exception levels that are using AArch32. [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#) summarizes how the AArch32 PE modes map onto the Exception levels.
[Chapter D4 The AArch64 Virtual Memory System Architecture](#) describes the control of the VMSA by exception levels that are using AArch64.
- For details of the VMSA differences in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

The main function of the VMSA is to perform address translation, and access permissions and memory attribute determination and checking, for memory accesses made by the PE. Address translation, and permissions and attribute determination and checking, is performed by a *stage* of address translation.

In VMSAv8-32, the *Memory Management Unit* (MMU) provides a number of stages of address translation. This chapter describes only the stages that are visible from Exception levels that are using AArch32, which are as follows:

For operation in Secure state

A single stage of address translation, for use when executing at PL1 or PL0. This is the *Secure PL1&0 stage 1* address translation stage.

For operation in Non-secure state

- A single stage of address translation for use when executing at PL2. This is the *Non-secure PL2 stage 1* address translation stage.
- Two stages of address translation for use when executing at PL1 or PL0. These are:
 - The *Non-secure PL1&0 stage 1* address translation stage.
 - The *Non-secure PL1&0 stage 2* address translation stage.

The System registers provide independent control of each supported stage of address translation, including a control to disable that stage of translation.

However, if the PE is executing at EL0 using AArch32 when EL1 is using AArch64 then it is using the VMSAv8-64 EL1&0 translation regime, described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

These features mean the VMSAv8-32 can support a hierarchy of software supervision, for example an Operating System and a hypervisor.

Each stage of address translation uses address translations and associated memory properties held in memory mapped tables called *translation tables*.

For information about how the MMU features differ if an implementation does not include all of the Exception levels, see [About address translation for VMSAv8-32 on page G4-4026](#).

The translation tables define the following properties:

Access to the Secure or Non-secure address map

The translation table entries determine whether an access from Secure state accesses the Secure or the Non-secure address map. Any access from Non-secure state accesses the Non-secure address map.

Memory access permission control

This controls whether a program is permitted to access a memory region. For instruction and data access, the possible settings are:

- No access.
- Read-only.
- Write-only. This is possible only in a translation regime with two stages of translation.
- Read/write.

For instruction accesses, additional controls determine whether instructions can be fetched and executed from the memory region.

If a PE attempts an access that is not permitted, a memory fault is signaled to the PE.

Memory region attributes

These describe the properties of a memory region. The top-level attribute, the Memory type, is one of Normal, or a type of Device memory, as follows:

- Both translation table formats support the following Device memory types:
 - Device-nGnRnE
 - Device-nGnRE
- The Long-descriptor translation table format supports, in addition, the following Device memory types:
 - Device-nGRE
 - Device-GRE

———— Note ————

ARMv8 added the Device-nGRE and Device-GRE memory types. Also, in versions of the ARM architecture before ARMv8:

- Device-nGnRnE memory is described as Strongly-ordered memory.
- Device-nGnRE memory is described as Device memory.

Normal memory regions can have additional attributes.

For more information, see [Memory types and attributes on page E2-2342](#).

Address translation mappings

An address translation maps an *input address* to an *output address*.

A stage 1 translation takes the address of an explicit data access or instruction fetch, a *virtual address* (VA), as the input address, and translates it to a different output address:

- If only one stage of translation is provided, this output address is the *physical address* (PA).
- If two stages of address translation are provided, the output address of the stage 1 translation is an *intermediate physical address* (IPA).

———— Note ————

In the ARMv8-32 architecture, a software agent, such as an Operating System, that uses or defines stage 1 memory translations, might be unaware of the distinction between IPA and PA.

A stage 2 translation translates the IPA to a PA.

The possible security states and privilege levels of memory accesses define a set of *translation regimes*, where a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. See [The VMSAv8-32 translation regimes on page G4-4024](#).

System registers control VMSAv8-32, including defining the location of the translation tables, and enabling and configuring the MMU, including enabling and disabling the different address translation stages. Also, they report any faults that occur on a memory access. For more information, see [Functional grouping of VMSAv8-32 System registers on page G4-4193](#).

The following sections give an overview of VMSSAv8-32, and of the implementation options for VMSSAv8-32:

- [The VMSSAv8-32 translation regimes.](#)
- [Address types used in a VMSSAv8-32 description on page G4-4025.](#)
- [Address spaces in VMSSAv8-32 on page G4-4025.](#)
- [About address translation for VMSSAv8-32 on page G4-4026.](#)

The remainder of the chapter fully describes the VMSSA, including the different implementation options, as summarized in [Organization of this chapter on page G4-4029.](#)

G4.1.1 The VMSSAv8-32 translation regimes

As introduced in [Address translation mappings on page G4-4023](#), a translation regime maps an input VA to the corresponding PA, using one or two stages of translation. [Figure G4-1](#) shows the VMSSAv8-32 translation regimes, and their associated translation stages and the Exception levels from which they are controlled.

Figure G4-1 VMSSAv8-32 translation regimes, and associated control

———— **Note** —————

Conceptually, a translation regime that has only a stage 1 address translation is equivalent to a regime with a fixed, flat stage 2 mapping from IPA to PA.

[Limited use of Privilege level in ARMv8 AArch32 state on page G1-3793](#) describes the mapping between the PE modes and the Privilege levels (PLs).

Alternative descriptions of the PL1&0 translation regime

The PL1&0 is described in terms of Privilege level because of the way the AArch32 PE modes map onto the Exception levels, as described in [Limited use of Privilege level in ARMv8 AArch32 state on page G1-3793](#). The description of this translation regime in terms of the Exception levels using depends on the current state of the PE, as follows:

- In Non-secure state, PL1 always maps to EL1, and therefore the Non-secure PL1&0 translation regime could be described as the Non-secure EL1&0 translation regime.
- In Secure state:
 - When EL3 is using AArch32, PL1 maps to EL3, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL3&0 translation regime,
 - When EL3 is using AArch64, Secure PL1 maps to Secure EL1, and therefore under these conditions the Secure PL1&0 translation regime could be described as the Secure EL1&0 translation regime,

However, these descriptions all refer to the same translation regime, with the same System registers associated with its stage 1 translations. Therefore, the regime is generally referred to as the PL1&0 translation regime.

———— **Note** —————

As [Figure G4-1](#) shows, Stage 2 translation is supported only in Non-secure state.

G4.1.2 Address types used in a VMSAv8-32 description

A description of VMSAv8-32 refers to the following address types.

———— **Note** ————

These descriptions relate to a VMSAv8-32 description and therefore sometimes differ from the generic definitions given in the Glossary.

Virtual address (VA)

An address used in an instruction, as a data or instruction address, is a Virtual Address (VA).

An address held in the PC, LR, or SP, is a VA.

The VA map runs from zero to the size of the VA space. For AArch32 state, the maximum VA space is 4GB, giving a maximum VA range of 0x00000000-0xFFFFFFFF.

Intermediate physical address (IPA)

In a translation regime that provides two stages of address translation, the IPA is the address after the stage 1 translation, and is the input address for the stage 2 translation.

In a translation regime that provides only one stage of address translation, the IPA is identical to the PA.

A VMSAv8-32 implementation provides only one stage of address translation:

- If the implementation does not include EL2.
- When executing in Secure state.
- When executing in Hyp mode.

Physical address (PA)

The address of a location in the Secure or Non-secure memory map. That is, an output address from the PE to the memory system.

G4.1.3 Address spaces in VMSAv8-32

For execution in AArch32 state, the ARMv8 architecture supports:

- A VA space of up to 32 bits. The actual width is IMPLEMENTATION DEFINED.
- An IPA space of up to 40 bits. The translation tables and associated System registers define the width of the implemented address space.

———— **Note** ————

AArch32 defines two translation table formats. The *Long-descriptor* format gives access to the full 40-bit IPA or PA space at a granularity of 4KB. The *Short-descriptor* format:

- Gives access to a 32-bit PA space at 4KB granularity.
- Gives access to a 40-bit PA space, but only at 16MB granularity, by the use of Supersections.

If an implementation includes EL3, the address maps are defined independently for Secure and Non-secure operation, providing two independent 40-bit address spaces, where:

- A VA accessed from Non-secure state can only be translated to the Non-secure address map.
- A VA accessed from Secure state can be translated to either the Secure or the Non-secure address map.

G4.1.4 About address translation for VMSAv8-32

Address translation is the process of mapping one address type to another, for example, mapping VAs to IPAs, or mapping VAs to PAs. A *translation table* defines the mapping from one address type to another, and a *Translation table base register (TTBR)* indicates the start of a translation table. Each implemented stage of address translation shown in [Figure G4-1 on page G4-4024](#) requires its own translation tables.

For PL1&0 stage 1 translations, the mapping can be split between two tables, one controlling the lower part of the VA space, and the other controlling the upper part of the VA space. This can be used, for example, so that:

- One table defines the mapping for operating system and I/O addresses, that do not change on a context switch.
- A second table defines the mapping for application-specific addresses, and therefore might require updating on a context switch.

The VMSAv8-32 implementation options determine the supported address translation stages. The following descriptions apply when all implemented Exception levels are using AArch32:

VMSAv8-32 without EL2 or EL3

Supports only a single PL1&0 stage 1 address translation. Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by [TTBR0](#) and [TTBR1](#), and controlled by [TTBCR](#).

VMSAv8-32 with EL3 but without EL2

Supports only the Secure PL1&0 stage 1 address translation and the Non-secure PL1&0 stage 1 address translation. In each security state, this stage of translation can be split between two sets of translation tables, with base addresses defined by the Secure and Non-secure copies of [TTBR0](#) and [TTBR1](#), and controlled by the Secure and Non-secure copies of [TTBCR](#).

VMSAv8-32 with EL2 but without EL3

The implementation supports the following stages of address translation:

Non-secure PL2 stage 1 address translation

The [HTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [HTCR](#).

Non-secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of [TTBR0](#) and [TTBR1](#) and controlled by the Non-secure instance of [TTBCR](#).

Non-secure PL1&0 stage 2 address translation

The [VTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [VTCR](#).

VMSAv8-32 with EL2 and EL3

The implementation supports all of the stages of address translation, as follows:

Secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Secure copies of [TTBR0](#) and [TTBR1](#), and controlled by the Secure instance of [TTBCR](#).

Non-secure PL2 stage 1 address translation

The [HTTBR](#) defines the base address of the translation table for this stage of address translation, controlled by [HTCR](#).

Non-secure PL1&0 stage 1 address translation

Translation of this stage of address translation can be split between two sets of translation tables, with base addresses defined by the Non-secure copies of [TTBR0](#) and [TTBR1](#) and controlled by the Non-secure instance of [TTBCR](#).

Non-secure PL1&0 stage 2 address translation

The **VTTBR** defines the base address of the translation table for this stage of address translation, controlled by **VTCR**.

Figure G4-2 shows the translation regimes and stages in a VMSAv8-32 implementation that includes all of the Exception levels, and indicates the PE mode that, typically, defines each set of translation tables, if that stage of address translation is controlled by a Privilege level that is using AArch32:

Figure G4-2 VMSAv8-32 address translation summary

————— Note —————

The term *Typically configured* is used in Figure G4-2 to indicate the expected software usage. However, stages of address translation used in AArch32 state can also be configured:

- From an Exception level higher than the Exception level of the configuring PE mode shown in Figure G4-2, regardless of whether that Exception level is using AArch32 or is using AArch64, except that a Non-secure Exception level can never configure a stage of address translation that is used in Secure state.
- From an Exception level that is using AArch64 and is higher than the level at which the translation stage is being used. For example, if Non-secure EL0 is the only Non-secure Exception level that is using AArch32, then the Non-secure PL1&0 stage of address translation is configured from Non-secure EL1, that is using AArch64.

In general:

- The translation from VA to PA can require multiple *stages* of address translation, as Figure G4-2 shows.
- A single stage of address translation takes an *input address* and translates it to an *output address*.

A full translation table lookup is called a *translation table walk*. It is performed automatically by hardware, and can have a significant cost in execution time. To support fine granularity of the VA to PA mapping, a single input address to output address translation can require multiple accesses to the translation tables, with each access giving finer granularity. Each access is described as a *level* of address lookup. The final level of the lookup defines:

- The required output address.
- The *attributes* and *access permissions* of the addressed memory.

Translation Lookaside Buffers (TLBs) reduce the average cost of a memory access by caching the results of translation table walks. TLBs behave as caches of the translation table information, and VMSAv8-32 provides TLB maintenance instructions for the management of TLB contents.

————— Note —————

The ARM architecture permits TLBs to hold any translation table entry that does not directly cause a Translation fault, an Address size fault, or an Access flag fault.

To reduce the software overhead of TLB maintenance, for the PL1&0 translation regimes VMSAv8-32 distinguishes between *Global pages* and *Process-specific pages*. The *Address Space Identifier (ASID)* identifies pages associated with a specific process and provides a mechanism for changing process-specific tables without having to maintain the TLB structures.

If an implementation includes EL2, the *virtual machine identifier (VMID)* identifies the current virtual machine, with its own independent ASID space. The TLB entries include this VMID information, meaning TLBs do not require explicit invalidation when changing from one virtual machine to another, if the virtual machines have different VMIDs. For stage 2 translations, all translations are associated with the current VMID. There is no mechanism to associate a particular stage 2 translation with multiple virtual machines.

Atomicity of register changes on changing virtual machine

From the viewpoint of software executing at Non-secure PL1 or PL0, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for the Non-secure PL1&0 translation regime. This means that all of the following registers must change atomically:

- The registers associated with the stage 1 translations:
 - MAIR0, MAIR1, AMAIR0, and AMAIR1.
 - TTBR0, TTBR1, TTBCR, and CONTEXTIDR.
 - SCTLR.
- The registers associated with the stage 2 translations:
 - VTTBR and VTCR.
 - HSCTLR.

———— Note —————

Only some bits of SCTLR affect the stage 1 translation, and only some bits of HSCTLR affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution using the Non-secure PL1&0 translation regime. However, when updated as part of a switch of virtual machines they are updated by software executing at EL2. This means the registers are out of context when they are updated, and no synchronization precautions are required.

Use of out-of-context translation regimes

The architecture requires that:

- When executing at EL3 or EL2, the PE must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.
- When executing at EL3 the PE must not use the registers associated with the EL2 translation regime for speculative memory accesses.
- When executing at EL3, EL2, or Non-secure EL1, the PE must not use the registers associated with the Secure PL1&0 translation regime for speculative memory accesses.

When entering an exception level on completion of a DSB instruction, no new memory accesses using any translation table entries from a translation regime of an exception level lower than the exception level that has been entered, will be observed by any observers to the extent that those accesses are required to be observed, as determined by the Shareability and Cacheability of those translation table entries.

———— Note —————

- This does not require that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

- This requirement does not imply that, on taking an exception to a higher Exception level, any translation table walks started before the exception was taken will be completed by the time the higher Exception level is entered, and therefore memory accesses required for such a translation table walk might, in effect, be performed speculatively. However, the execution of a DSB on entry to the higher Exception level ensures that these accesses are complete.

G4.1.5 Organization of this chapter

The remainder of this chapter is organized as follows.

The first part of the chapter describes address translation and the associated memory properties held in the translation table entries, in the following sections:

- [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4031.](#)
- [Translation tables on page G4-4035.](#)
- [Secure and Non-secure address spaces on page G4-4038.](#)
- [The VMSAv8-32 Short-descriptor translation table format on page G4-4040.](#)
- [The VMSAv8-32 Long-descriptor translation table format on page G4-4049.](#)
- [Memory access control on page G4-4068.](#)
- [Memory region attributes on page G4-4077.](#)
- [Translation Lookaside Buffers \(TLBs\) on page G4-4089.](#)
- [TLB maintenance requirements on page G4-4093.](#)

[Caches in VMSAv8-32 on page G4-4106](#) describes VMSAv8-32-specific cache requirements.

The following sections describe aborts on VMSAv8-32 memory accesses, and how these and other faults are reported:

- [VMSAv8-32 memory aborts on page G4-4110.](#)
- [Exception reporting in a VMSAv8-32 implementation on page G4-4123.](#)

[Address translation instructions on page G4-4142](#) describes these operations, and how they relate to address translation.

A number of sections then describe the System registers for VMSAv8-32. The following sections give general information about the System registers, and the organization of the registers in the primary encoding spaces, (coproc==0b1110) and (coproc==0b1111) for these registers:

- [About the System registers for VMSAv8-32 on page G4-4148.](#)
- [VMSAv8-32 organization of registers in the \(coproc==0b1110\) encoding space on page G4-4172.](#)
- [VMSAv8-32 organization of registers in the \(coproc==0b1111\) encoding space on page G4-4175.](#)
- [Functional grouping of VMSAv8-32 System registers on page G4-4193.](#)

The following sections then describe each of the functional groups of the System registers in the (coproc==0b1111) encoding space, including a full description of each register in the group:

- [Identification registers, functional group on page G4-4194.](#)
- [Virtual memory control registers, functional group on page G4-4196.](#)
- [Exception and fault handling registers, functional group on page G4-4200.](#)
- [General system control registers, functional group on page G4-4195.](#)
- [Lockdown, DMA, and TCM features, functional group on page G4-4205.](#)
- [Cache maintenance instructions, functional group on page G4-4201.](#)
- [TLB maintenance instructions, functional group on page G4-4202.](#)
- [Address translation instructions, functional group on page G4-4204.](#)
- [Legacy feature registers, functional group on page G4-4211.](#)
- [Performance Monitors Extension registers, functional group on page G4-4205.](#)
- [Security registers, functional group on page G4-4199.](#)
- [Virtualization registers, functional group on page G4-4197.](#)
- [IMPLEMENTATION DEFINED registers, functional group on page G4-4211.](#)

———— **Note** —————

The System registers in the (coproc==0b1110) encoding space provide the following functionality:

- Self-hosted debug. These registers are described in [Debug registers on page G6-4668](#).
- The System register interface to a trace macrocell. These registers are not described in this manual.
- Jazelle registers. These registers are summarized in [Legacy feature registers, functional group on page G4-4211](#).

Therefore, there is no summary of these registers by functional groups.

[Pseudocode description of VMSSAv8-32 memory system operations on page G4-4215](#) then summarizes the pseudocode functions that describe many features of VMSSAv8-32 operation.

G4.2 The effects of disabling address translation stages on VMSAv8-32 behavior

About VMSAv8-32 on page G4-4022 defines the translation regimes and the associated stages of address translation, each of which has its own System registers for control and configuration. VMSAv8-32 includes an enable bit for each stage of address translation, as follows:

- **SCTLR.M**, in the Secure instance of the register, controls Secure PL1&0 stage 1 address translation.
- **SCTLR.M**, in the Non-secure instance of the register, controls Non-secure PL1&0 stage 1 address translation.
- **HCR.VM** controls Non-secure PL1&0 stage 2 address translation.
- **HSCTLR.M** controls Non-secure PL2 stage 1 address translation.

Note

- The descriptions throughout this chapter describe address translation as seen by Exception levels that are using AArch32. However, for the Non-secure PL1&0 translation regime, the stage 2 translation:
 - Is controlled by the **HCR** if EL2 is using AArch32.
 - Is controlled by the **HCR_EL2** if EL2 is using AArch64.For this reason, links to the **HCR** link to a table that disambiguates between the AArch32 **HCR** and the AArch64 **HCR_EL2**.
- If EL2 is using AArch64, then the equivalent of the Non-secure PL2 translation regime is described in *Chapter D4 The AArch64 Virtual Memory System Architecture*, not in this chapter.

The following sections describe the effect on VMSAv8-32 behavior of disabling each stage of translation:

- *VMSAv8-32 behavior when stage 1 address translation is disabled.*
- *VMSAv8-32 behavior when stage 2 address translation is disabled on page G4-4033.*
- *Behavior of instruction fetches when all associated address translations are disabled on page G4-4033.*

Enabling stages of address translation on page G4-4033 gives more information about each stage of address translation, in particular after a reset on an implementation that includes EL3.

G4.2.1 VMSAv8-32 behavior when stage 1 address translation is disabled

When stage 1 address translation is disabled, memory accesses that would otherwise be translated by that stage of address translation are treated as follows:

Non-secure PL1 and PL0 accesses when EL2 is implemented and HCR.DC is set to 1

In an implementation that includes EL2, for an access from a Non-secure PL1 or PL0 mode when **HCR.DC** is set to 1, the stage 1 translation assigns the Normal Non-shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate memory attributes.

See also *Effect of the HCR.DC bit on page G4-4032*.

All other accesses

For all other accesses, when a stage 1 address translation is disabled, the assigned attributes depend on whether the access is a data access or an instruction access, as follows:

Data access

The stage 1 translation assigns the Device-nGnRnE memory type.

Instruction access

The stage 1 translation assigns Normal memory attribute, with the Cacheability and Shareability attributes determined by the value of:

- The Secure instance of **SCTLR.I** for the Secure PL1&0 translation regime.
- The Non-secure instance of **SCTLR.I** for the Non-secure PL1&0 translation regime.
- **HSCTLR.I** for the Non-secure PL2 translation regime.

In these cases, the meaning of the I bit is as follows:

When I is set to 0

The stage 1 translation assigns the attributes Outer Shareable, Non-cacheable.

When I is set to 1

The stage 1 translation assigns the attributes Inner Write-Through Read-Allocate No Write-Allocate, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.

Note

On some implementations, if the [SCTLR.TRE](#) bit is set to 0 then this behavior can be changed by the remap settings in the memory remap registers. The details of TEX remap when [SCTLR.TRE](#) is set to 0 are IMPLEMENTATION DEFINED, see [SCTLR.TRE](#), [SCTLR.M](#), and the effect of the TEX remap registers on page G4-4082.

For this stage of translation, no memory access permission checks are performed, and therefore no MMU faults relating to this stage of translation can be generated.

Note

Alignment checking is performed, and therefore Alignment faults can occur.

For every access, when stage 1 translation is disabled, the output address of the stage 1 translation is equal to the input address. This is called a flat address mapping. If the implementation supports output addresses of more than 32 bits then the output address bits above bit[31] are zero. For example, for a VA to PA translation on an implementation that supports 40-bit PAs, PA[39:32] is 0x00.

For a Non-secure PL1 or PL0 access, if the PL1&0 stage 2 address translation is enabled, the stage 1 memory attribute assignments and output address can be modified by the stage 2 translation.

See also [Behavior of instruction fetches when all associated address translations are disabled](#) on page G4-4033.

Effect of the HCR.DC bit

The [HCR.DC](#) bit determines the default memory attributes assigned for the first stage of the Non-secure PL1&0 translation regime when that stage of translation is disabled.

When executing in a Non-secure PL1 or PL0 mode with [HCR.DC](#) set to 1:

- For all purposes other than reading the value of the [SCTLR](#), the PE behaves as if the value of the [SCTLR.M](#) bit is 0. This means Non-secure PL1&0 stage 1 address translation is disabled.
- For all purposes other than reading the value of the [HCR](#), the PE behaves as if the value of the [HCR.VM](#) bit is 1. This means Non-secure PL1&0 stage 2 address translation is enabled.

The effect of [HCR.DC](#) might be held in TLB entries associated with a particular VMID. Therefore, if software executing at EL2 changes the [HCR.DC](#) value without also changing the current VMID, it must also invalidate all TLB entries associated with the current VMID. Otherwise, the behavior of Non-secure software executing at EL1 or EL0 is CONstrained UNPREDICTABLE, see [CONstrained UNPREDICTABLE behaviors due to caching of control or data values](#) on page K1-5461.

Effect of disabling translation on maintenance and address translation instructions

Cache maintenance instructions act on the target cache whether address translation is enabled or not, and regardless of the values of the memory attributes. However, if a stage of translation is disabled, they use the flat address mapping for that stage, and all mappings are considered global.

TLB invalidate operations act on the target TLB whether address translation is enabled or not.

When the Non-secure PL1&0 stage 1 address translation is disabled, any [ATS1C**](#) or [ATS12NSO**](#) address translation instruction that accesses the Non-secure state translation reflects the effect of the [HCR.DC](#) bit. For more information about these operations see [Address translation instructions](#) on page G4-4142.

G4.2.2 VMSAv8-32 behavior when stage 2 address translation is disabled

When stage 2 address translation is disabled:

- The IPA output from the stage 1 translation maps flat to the PA
- The memory attributes and permissions from the stage 1 translation apply to the PA.

If the stage 1 address translation and the stage 2 address translation are both disabled, see [Behavior of instruction fetches when all associated address translations are disabled](#).

G4.2.3 Behavior of instruction fetches when all associated address translations are disabled

The information in this section applies to memory accesses:

- From Secure PL1 and PL0 modes, when the Secure PL1&0 stage 1 address translation is disabled
- From Hyp mode, when the Non-secure PL2 stage 1 address translation is disabled
- From Non-secure PL1 and PL0 modes, when all of the following apply:
 - The Non-secure PL1&0 stage 1 address translation is disabled.
 - The Non-secure PL1&0 stage 2 address translation is disabled.
 - [HCR.DC](#) is set to 0.

In these cases, when execution is in AArch32 state a memory location might be accessed as a result of an instruction fetch if either:

- The memory location is in the same 4KB block of memory, aligned to 4KB, as an instruction which a simple sequential execution of the program either requires to be fetched now or has required to be fetched since the last reset, or is in the 4KB block immediately following such a block.
- The memory location is the target of a direct branch that a simple sequential execution of the program would have taken since the most recent of:
 - The last reset.
 - If the branch predictor is architecturally invisible, the last synchronization of instruction cache maintenance targeting the address of the branch instruction.
 - If the branch predictor is not architecturally invisible, the last synchronization of branch predictor maintenance targeting the address of the branch instruction.

These accesses can be caused by speculative instruction fetches, regardless of whether the prefetched instruction is committed for execution.

———— **Note** ————

To ensure architectural compliance, software must ensure that both of the following apply:

- Instructions that will be executed when address translation is disabled are located in 4KB blocks of the address space that contain only memory that is tolerant to speculative accesses.
- Each 4KB block of the address space that immediately follows a 4KB block that holds instructions that will be executed when address translation is disabled also contains only memory that is tolerant to speculative accesses.

G4.2.4 Enabling stages of address translation

On powerup or reset, only the [SCTLR.M](#) bit for the Exception level and Security state entered on reset is reset to 0, disabling address translation for the initial state of the PE. All other [SCTLR.M](#) and [HSCTLR.M](#) bits that are implemented are UNKNOWN after the reset.

This means, on powerup or reset:

- On an implementation that includes EL3, where EL3 is using AArch32:
 - The PL1&0 stage 1 address translation enable bit, **SCTLR.M**, is Banked, meaning there are separate enables for operation in Secure and Non-secure state.
 - If EL3 is using AArch32, only the Secure instance of the **SCTLR.M** bit resets to 0, disabling the Secure state PL1&0 stage 1 address translation. The reset value of the Non-secure instance of **SCTLR.M** is UNKNOWN.
- On an implementation that includes EL2, where EL2 is using AArch32, the **HSCTLR.M** bit, that controls the Non-secure PL2 stage 1 address translation:
 - If the implementation does not include EL3, resets to 0.
 - Otherwise, is UNKNOWN.
- On an implementation that does not include either EL2 or EL3, there is a single stage of translation. This is controlled by **SCTLR.M**, that resets to 0.

———— **Note** —————

If, for the software that enables or disables a stage of address translation, the input address of a stage 1 translation differs from the output address of that stage 1 translation, and the software is running in translation regime that is affected by that stage of translation, then the requirement to synchronize changes to the System registers means it is uncertain where in the instruction stream the change of the translation takes place. For this reason, ARM strongly recommends that the input address and the output address are identical in this situation.

G4.3 Translation tables

VMSAv8-32 defines two alternative translation table formats:

Short-descriptor format

It uses 32-bit descriptor entries in the translation tables, and provides:

- Up to two levels of address lookup.
- 32-bit input addresses.
- Output addresses of up to 40 bits.
- Support for PAs of more than 32 bits by use of supersections, with 16MB granularity.
- Support for No access, Client, and Manager domains.

Long-descriptor format

It uses 64-bit descriptor entries in the translation tables, and provides:

- Up to three levels of address lookup.
- Input addresses of up to 40 bits, when used for stage 2 translations.
- Output addresses of up to 40 bits.
- 4KB assignment granularity across the entire PA range.
- No support for domains, all memory regions are treated as in a Client domain.
- Fixed 4KB table size, unless truncated by the size of the input address space.

Note

- Translation with a 40-bit input address range requires two concatenated 4KB top-level tables, aligned to 8KB.
- The VMSAv8-64 Long-descriptor translation table format is generally similar to this format, but supports input and output addresses of up to 48 bits, and has an assignment granularity and table size defined by its *translation granule*. This can be 4KB, 16KB, or 64KB. See [The VMSAv8-64 translation table format on page D4-1756](#).

In all implementations, of the possible address translations shown in [Figure G4-2 on page G4-4027](#), for stages of address translation that are using AArch32:

- In a particular Security state, the translation tables for the PL1&0 stage 1 translations can use either translation table format, and the `TTBCR.EAE` bit indicates the current translation table format.
- The translation tables for the Non-secure PL2 stage 1 translations, and for the Non-secure PL1&0 stage 2 translations, must use the Long-descriptor translation table format.

Many aspects of performing a translation table walk depend on the current translation table format. Therefore, the following sections describe the two formats, including how the MMU performs a translation table walk for each format:

- [The VMSAv8-32 Short-descriptor translation table format on page G4-4040](#).
- [The VMSAv8-32 Long-descriptor translation table format on page G4-4049](#).

The following subsections describe aspects of the translation tables and translation table walks, for memory accesses from AArch32 state, that are independent of the translation table format:

- [Translation table walks for memory accesses using VMSAv8-32 translation regimes on page G4-4036](#).
- [Information returned by a translation table lookup on page G4-4036](#).
- [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4037](#).
- [Control of translation table walks on a TLB miss on page G4-4038](#).
- [Access to the Secure or Non-secure physical address map on page G4-4038](#).

See also [TLB maintenance requirements on page G4-4093](#).

G4.3.1 Translation table walks for memory accesses using VMSAv8-32 translation regimes

A translation table walk occurs as the result of a TLB miss, and starts with a read of the appropriate starting-level translation table. The result of that read determines whether additional translation table reads are required, for this stage of translation, as described in either:

- [Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4046.](#)
- [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4063.](#)

Note

When using the Short-descriptor translation table format, the starting level for a translation table walk is always a level 1 lookup. However, with the Long-descriptor translation table format, the starting-level can be either a level 1 or a level 2 lookup.

For the PL1&0 stage 1 translations, [SCTLR.EE](#) determines the endianness of the translation table lookups. [SCTLR](#) is Banked, and therefore the endianness is determined independently for each Security state.

[HSCTLR.EE](#) defines the endianness for the Non-secure PL2 stage 1 and Non-secure PL1&0 stage 2 translations.

Note

Dynamically changing translation table endianness

Because any change to [SCTLR.EE](#) or [HSCTLR.EE](#) requires synchronization before it is visible to subsequent operations, ARM strongly recommends that:

- [SCTLR.EE](#) is changed only when either:
 - Executing in a mode that does not use the translation tables affected by [SCTLR.EE](#).
 - Executing with [SCTLR.M](#) set to 0.
- [HSCTLR.EE](#) is changed only when either:
 - Executing in a mode that does not use the translation tables affected by [HSCTLR.EE](#).
 - Executing with [HSCTLR.M](#) set to 0.

The physical address of the base of the starting-level translation table is determined from the appropriate [TTBR](#), see [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4037.](#)

For more information, see [Ordering and completion of TLB maintenance instructions on page G4-4096.](#)

Translation table walks must access data or unified caches, or data and unified caches, of other agents participating in the coherency protocol, according to the Shareability attributes described in the [TTBR](#). These Shareability attributes must be consistent with the Shareability attributes for the translation tables themselves.

G4.3.2 Information returned by a translation table lookup

When an associated stage of address translation is enabled, a memory access requires one or more translation table lookups. If the required translation table descriptor is not held in a TLB, a translation table walk is performed to obtain the descriptor. A lookup, whether from the TLB or as the result of a translation table walk, returns both:

- An output address that corresponds to the input address for the lookup.
- A set of properties that correspond to that output address.

The returned properties are classified as providing *address map control*, *access controls*, or *region attributes*. This classification determines how the descriptions of the properties are grouped. The classification is based on the following model:

Address map control

Memory accesses from Secure state can access either the Secure or the Non-secure address map, as summarized in [Access to the Secure or Non-secure physical address map on page G4-4038.](#)

Memory accesses from Non-secure state can only access the Non-secure address map.

Access controls

Determine whether the PE, in its current state, can access the output address that corresponds to the given input address. If not, an MMU fault is generated and there is no memory access.

Memory access control on page G4-4068 describes the properties in this group.

Attributes Are valid only for an output address that the PE, in its current state, can access. The attributes define aspects of the required behavior of accesses to the target memory region.

Memory region attributes on page G4-4077 describes the properties in this group.

G4.3.3 Determining the translation table base address in the VMSAv8-32 translation regimes

On a TLB miss, the VMSA must perform a translation table walk, and therefore must find the base address of the translation table to use for its lookup. A TTBR holds this address. As [Figure G4-2 on page G4-4027](#) shows:

- For a Non-secure PL2 stage 1 translation, the [HTTBR](#) holds the required base address. The [HTCR](#) is the control register for these translations.
- For a Non-secure PL1&0 stage 2 translation, the [VTTBR](#) holds the required base address. The [VTCTCR](#) is the control register for these translations.
- For a PL1&0 stage 1 translation, either [TTBR0](#) or [TTBR1](#) holds the required base address. The [TTBCR](#) is the control register for these translations.

The Non-secure copies of [TTBR0](#), [TTBR1](#), and [TTBCR](#), relate to the Non-secure PL1&0 stage 1 translation. The Secure copies of [TTBR0](#), [TTBR1](#), and [TTBCR](#), relate to the Secure PL1&0 stage 1 translation.

For the PL1&0 translation table walks:

- [TTBR0](#) can be configured to describe the translation of VAs in the entire address map, or to describe only the translation of VAs in the lower part of the address map.
- If [TTBR0](#) is configured to describe the translation of VAs in the lower part of the address map, [TTBR1](#) is configured to describe the translation of VAs in the upper part of the address map.

The contents of the appropriate instance of the [TTBCR](#) determine whether the address map is separated into two parts, and where the separation occurs. The details of the separation depend on the current translation table format, see:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format* on page G4-4045.
- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format* on page G4-4057.

[Example G4-1](#) shows a typical use of the two sets of translation tables:

Example G4-1 Example use of TTBR0 and TTBR1

An example of using the two TTBRs for PL1&0 stage 1 address translations is:

TTBR0 Used for process-specific addresses.

Each process maintains a separate level 1 translation table. On a context switch:

- [TTBR0](#) is updated to point to the level 1 translation table for the new context.
- [TTBCR](#) is updated if this change changes the size of the translation table.
- The [CONTEXTIDR](#) is updated.

[TTBCR](#) can be programmed so that all translations use [TTBR0](#) in a manner compatible with architecture versions before ARMv6.

TTBR1 Used for operating system and I/O addresses, that do not change on a context switch.

G4.3.4 Control of translation table walks on a TLB miss

Two bits in the **TCR** for the translation stage required by a memory access control whether a translation table walk is performed on a TLB miss. These two bits are the:

- **PD0** and **PD1** bits, on a PE using the Short-descriptor translation table format.
- **EPD0** and **EPD1** bits, on a PE using the Long-descriptor translation table format.

———— **Note** ————

For the VMSAv8-32 translation regimes, the different bit names are because the bits are in different positions in **TTBCR**, depending on the translation table format.

The effect of these bits is:

{E}PDx == 0 If a TLB miss occurs based on **TTBRx**, a translation table walk is performed. The current security state determines whether the memory access is Secure or Non-secure.

{E}PDx == 1 If a TLB miss occurs based on **TTBRx**, a level 1 Translation fault is returned, and no translation table walk is performed.

G4.3.5 Access to the Secure or Non-secure physical address map

As stated in *Address spaces in VMSAv8-32 on page G4-4025*, a PE can access independent Secure and Non-secure address maps. When the PL1 Exception level is using AArch32, these are defined by the translation tables identified by the Secure **TTBR0** and **TTBR1**. In both translation table formats in the Secure translation tables, the **NS** bit in a descriptor indicates whether the descriptor refers to the Secure or the Non-secure address map:

NS == 0 Access the Secure physical address space.

NS == 1 Access the Non-secure physical address space.

———— **Note** ————

In the Non-secure translation tables, the corresponding bit is **SBZ**. Non-secure accesses always access the Non-secure physical address space, regardless of the value of this bit.

The Long-descriptor translation table format extends this control, adding an **NSTable** bit to the Secure translation tables, as described in *Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G4-4056*. In the Non-secure translation tables, the corresponding bit is **SBZ**, and Non-secure accesses ignore the value of this bit.

The following sections describe the address map controls in the two implementations:

- *Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4045.*
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4056.*

The following subsection gives more information.

Secure and Non-secure address spaces

EL3 provides two physical address spaces, a Secure physical address space and a Non-secure physical address space.

As described in *Access to the Secure or Non-secure physical address map*, for the PL1&0 stage 1 translations when controlled from an Exception level using AArch32, the registers that control the stage of translation, **TTBR0**, **TTBR1**, and **TTBCR**, are Banked between Secure and Non-secure versions, and the Security state of the PE when it performs a memory access selects the corresponding version of the registers. This means there are independent Secure and Non-secure versions of these translation tables, and translation table walks are made to the physical address space corresponding to the security state of the translation tables used.

For a translation table walk caused by a memory access from Non-secure state, all memory accesses are to the Non-secure address space.

For a translation table walk caused by a memory access from Secure state:

- When address translation is using the Long-descriptor translation table format:
 - The initial lookup performed must access the Secure address space.
 - If a table descriptor read from the Secure address space has the NSTable bit set to 0, then the next level of lookup is from the Secure address space.
 - If a table descriptor read from the Secure address space has the NSTable bit set to 1, then the next level of lookup, and any subsequent level of lookup, is from the Non-secure address space.

For more information, see [Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4056](#).

- Otherwise, all memory accesses are to the Secure address space.

Note

- When executing in Non-secure state, additional translations are supported. For memory accesses from AArch32 state these are:
 - Non-secure PL2 stage 1 translation.
 - Non-secure PL1&0 stage 2 translation.These translations can access only the Non-secure address space.
 - A system implementation can alias parts of the Secure physical address space to the Non-secure physical address space in an implementation-specific way. As with any other aliasing of physical memory, the use of aliases in this way can require the use of cache maintenance instructions to ensure that changes to memory made using one alias of the physical memory are visible to accesses to the other alias of the physical memory.
-

G4.4 The VMSAv8-32 Short-descriptor translation table format

The Short-descriptor translation table format supports a memory map based on memory sections or pages:

Supersections Consist of 16MB blocks of memory. Support for Supersections is optional, except that an implementation that supports more than 32 bits of Physical Address must also support Supersections to provide access to the entire Physical Address space.

Sections Consist of 1MB blocks of memory.

Large pages Consist of 64KB blocks of memory.

Small pages Consist of 4KB blocks of memory.

Supersections, Sections and Large pages map large regions of memory using only a single TLB entry.

———— **Note** —————

Whether a VMSAv8-32 implementation of the Short-descriptor format translation tables supports supersections is IMPLEMENTATION DEFINED.

When using the Short-descriptor translation table format, two levels of translation tables are held in memory:

Level 1 table

Holds *level 1 descriptors* that contain the base address and

- Translation properties for a Section and Supersection.
- Translation properties and pointers to a level 2 table for a Large page or a Small page.

Level 2 tables

Hold *level 2 descriptors* that contain the base address and translation properties for a Small page or a Large page. With the Short-descriptor format, level 2 tables can be referred to as *Page tables*.

A level 2 table requires 1KB of memory.

In the translation tables, in general, a descriptor is one of:

- An invalid or fault entry.
- A Page table entry, that points to a next-level translation table.
- A page or section entry, that defines the memory properties for the access.
- A reserved format.

Bits[1:0] of the descriptor give the primary indication of the descriptor type.

[Figure G4-3 on page G4-4041](#) gives a general view of address translation when using the Short-descriptor translation table format.

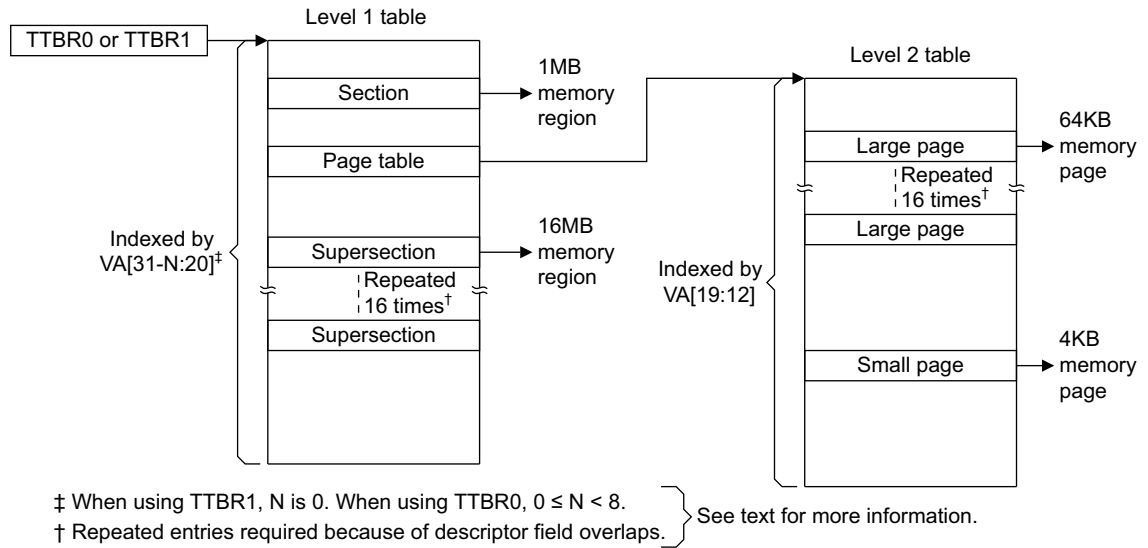

Figure G4-3 General view of address translation using VMSAv8-32 Short-descriptor format translation tables

Additional requirements for Short-descriptor format translation tables on page G4-4044 describes why, when using the Short-descriptor format, Supersection and Large page entries must be repeated 16 times, as shown in Figure G4-3.

VMSAv8-32 Short-descriptor translation table format descriptors, Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4044, and Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4045 describe the format of the descriptors in the Short-descriptor format translation tables.

The following sections then describe the use of this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format on page G4-4045.*
- *Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format on page G4-4046.*

G4.4.1 VMSAv8-32 Short-descriptor translation table format descriptors

The following sections describe the formats of the entries in the Short-descriptor translation tables:

- *Short-descriptor translation table level 1 descriptor formats on page G4-4042.*
- *Short-descriptor translation table level 2 descriptor formats on page G4-4043.*

For more information about level 2 translation tables see *Additional requirements for Short-descriptor format translation tables on page G4-4044*.

————— Note —————

Previous versions of the *ARM Architecture Reference Manual*, and some other documentation, describes the AP[2] bit in the translation table entries as the APX bit.

Information returned by a translation table lookup on page G4-4036 describes the classification of the non-address fields in the descriptors as address map control, access control, or attribute fields.

Short-descriptor translation table level 1 descriptor formats

Each entry in the level 1 table describes the mapping of the associated 1MB VA range.

Figure G4-4 shows the possible level 1 descriptor formats.

Figure G4-4 VMSAv8-32 Short-descriptor level 1 descriptor formats

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

0b00, Invalid entry

The associated VA is unmapped, and any attempt to access it generates a Translation fault.

Bits[31:2] of the descriptor are IGNORED, see *IGNORED* on page Glossary-5718. This means software can use these bits for its own purposes.

0b01, Page table

The descriptor gives the address of a level 2 translation table, that specifies the mapping of the associated 1MByte VA range.

0b10, Section or Supersection

The descriptor gives the base address of the Section or Supersection. Bit[18] determines whether the entry describes a Section or a Supersection.

This encoding also defines the PXN bit as 0.

0b11, Section or Supersection, if the implementation supports the PXN attribute

This encoding is identical to 0b10, except that it defines the PXN bit as 1.

Note

A VMSAv8-32 implementation can use the Short-descriptor translation table format for the PL1&0 stage 1 translations, by setting `TTBCR.EAE` to 0.

The address information in the level 1 descriptors is:

- Page table** Bits[31:10] of the descriptor are bits[31:10] of the address of a Page table.
- Section** Bits[31:20] of the descriptor are bits[31:20] of the address of the Section.
- Supersection** Bits[31:24] of the descriptor are bits[31:24] of the address of the Supersection.
 Optionally, bits[8:5, 23:20] of the descriptor are bits[39:32] of the extended Supersection address.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see *Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors* on page G4-4044.

Short-descriptor translation table level 2 descriptor formats

Figure G4-5 shows the possible formats of a level 2 descriptor.

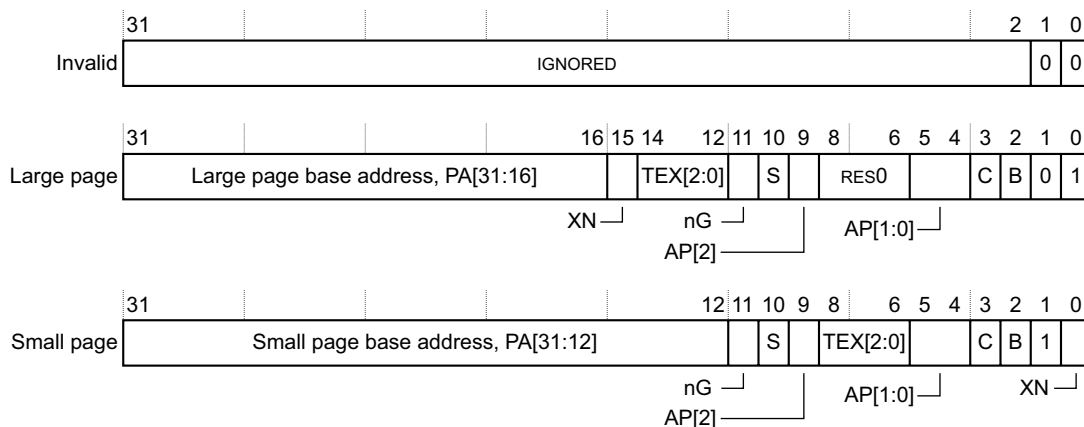

Figure G4-5 Short-descriptor level 2 descriptor formats

Descriptor bits[1:0] identify the descriptor type. The encoding of these bits is:

0b00, Invalid entry

The associated VA is unmapped, and attempting to access it generates a Translation fault.

Bits[31:2] of the descriptor are *IGNORED*, see *IGNORED* on page Glossary-5718. This means software can use these bits for its own purposes.

0b01, Large page

The descriptor gives the base address and properties of the Large page.

0b1x, Small page

The descriptor gives the base address and properties of the Small page.

In this descriptor format, bit[0] of the descriptor is the XN bit.

The address information in the level 2 descriptors is:

- Large page** Bits[31:16] of the descriptor are bits[31:16] of the address of the Large page.
- Small page** Bits[31:12] of the descriptor are bits[31:12] of the address of the Small page.

For the Non-secure PL1&0 translation tables, the address in the descriptor is the IPA of the Page table, Section, or Supersection. Otherwise, the address is the PA of the Page table, Section, or Supersection.

For descriptions of the other fields in the descriptors, see [Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors](#).

Additional requirements for Short-descriptor format translation tables

When using Supersection or Large page descriptors in the Short-descriptor translation table format, the input address field that defines the Supersection or Large page descriptor address overlaps the table address field. In each case, the size of the overlap is 4 bits. The following diagrams show these overlaps:

- [Figure K7-14 on page K7-5566](#) for the level 1 translation table entry for a Supersection.
- [Figure K7-16 on page K7-5568](#) for the level 2 translation table entry for a Large page.

Considering the case of using Large page descriptors in a level 2 translation table, this overlap means that for any specific Large page, the bottom four bits of the level 2 translation table entry might take any value from 0b0000 to 0b1111. Therefore, each of these sixteen index values must point to a separate copy of the same descriptor.

This means that each Large page or Supersection descriptor must:

- Occur first on a sixteen-word boundary.
- Be repeated in 16 consecutive memory locations.

G4.4.2 Memory attributes in the VMSAv8-32 Short-descriptor translation table format descriptors

This section describes the descriptor fields other than the descriptor type field and the address field:

TEX[2:0], C, B

Memory region attribute bits, see [Memory region attributes on page G4-4077](#).

These bits are not present in a descriptor for a Page table.

XN bit

The Execute-never bit. Determines whether the PE can execute software from the addressed region, see [Execute-never restrictions on instruction fetching on page G4-4071](#).

This bit is not present in a descriptor for a Page table.

PXN bit

The Privileged execute-never bit. Determines whether the PE can execute software from the region when executing at PL1, see [Execute-never restrictions on instruction fetching on page G4-4071](#).

———— Note —————

Memory accesses by software executing at EL2 always use the Long-descriptor translation table format.

When this bit is set to 1 in the descriptor for a Page table, it indicates that all memory pages described in the corresponding Page table are Privileged execute-never.

NS bit

Non-secure bit. Specifies whether the translated PA is in the Secure or Non-secure address map, see [Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format on page G4-4045](#).

This bit is not present in level 2 descriptors. The value of the NS bit in a level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

Domain

Domain field, see [Domains, Short-descriptor format only on page G4-4073](#).

This field is not present in a Supersection entry. Memory described by Supersections is in domain 0.

This bit is not present in level 2 descriptors. The value of the Domain field in the level 1 descriptor for a Page table applies to all entries in the corresponding level 2 translation table.

An IMPLEMENTATION DEFINED bit

This bit is not present in level 2 descriptors.

AP[2], AP[1:0]

Access Permissions bits, see [Memory access control on page G4-4068](#).

AP[0] can be configured as the *Access flag*, see [The Access flag on page G4-4074](#).

These bits are not present in a descriptor for a Page table.

S bit

Shareable bit. Used in determining the Shareability of the addressed region, see [Memory region attributes on page G4-4077](#).

———— **Note** —————

The naming of this bit as the *Shareable* bit is carried forward from early versions of the ARM architecture. This name is no longer an adequate description of the interpretation of the bit.

This bit is not present in a descriptor for a Page table.

nG bit

The not global bit. If a lookup using this descriptor is cached in a TLB, determines whether the TLB entry applies to all ASID values, or only to the current ASID value. See [Global and process-specific translation table entries on page G4-4089](#).

This bit is not present in a descriptor for a Page table.

Bit[18], when bits[1:0] indicate a Section or Supersection descriptor

- | | |
|----------|-----------------------------------|
| 0 | Descriptor is for a Section. |
| 1 | Descriptor is for a Supersection. |

G4.4.3 Control of Secure or Non-secure memory access, VMSAv8-32 Short-descriptor format

[Access to the Secure or Non-secure physical address map on page G4-4038](#) describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Short-descriptor translation table format, the NS bit is defined only in the level 1 translation tables. This means that, in a level 1 descriptor for a Page table, the NS bit defines the physical address space, Secure or Non-secure, for all of the Large pages and Small pages of memory described by that table.

The NS bit of a level 1 descriptor for a Page table has no effect on the physical address space in which that translation table is held. As stated in [Secure and Non-secure address spaces on page G4-4038](#), the physical address of that translation table is in:

- The Secure address space if the translation table walk is in Secure state.
- The Non-secure address space if the translation table walk is in Non-secure state.

This means the granularity of the Secure and Non-secure memory spaces is 1MB. However, in these memory spaces, table entries can define physical memory regions with a granularity of 4KB.

G4.4.4 Selecting between TTBR0 and TTBR1, VMSAv8-32 Short-descriptor translation table format

As described in [Determining the translation table base address in the VMSAv8-32 translation regimes on page G4-4037](#), two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. When using the Short-descriptor translation table format, the value of **TTBCR.N** indicates the number of most significant bits of the input VA that determine whether **TTBR0** or **TTBR1** holds the required translation table base address, as follows:

- If N == 0 then use **TTBR0**. Setting **TTBCR.N** to zero disables use of a second set of translation tables.
- if N > 0 then:
 - If bits[31:32-N] of the input VA are all zero then use **TTBR0**.
 - Otherwise use **TTBR1**.

Table G4-1 shows how the value of N determines the lowest address translated using TTBR1, and the size of the level 1 translation table addressed by TTBR0.

Table G4-1 Effect of TTBCR.N on address translation, Short-descriptor format

| TTBCR.N | First address translated with TTBR1 | TTBR0 table | |
|---------|-------------------------------------|-------------|-------------|
| | | Size | Index range |
| 0b000 | TTBR1 not used | 16KB | VA[31:20] |
| 0b001 | 0x80000000 | 8KB | VA[30:20] |
| 0b010 | 0x40000000 | 4KB | VA[29:20] |
| 0b011 | 0x20000000 | 2KB | VA[28:20] |
| 0b100 | 0x10000000 | 1KB | VA[27:20] |
| 0b101 | 0x08000000 | 512 bytes | VA[26:20] |
| 0b110 | 0x04000000 | 256 bytes | VA[25:20] |
| 0b111 | 0x02000000 | 128 bytes | VA[24:20] |

Whenever TTBCR.N is nonzero, the size of the translation table addressed by TTBR1 is 16KB.

Figure G4-6 shows how the value of TTBCR.N controls the boundary between VAs that are translated using TTBR0, and VAs that are translated using TTBR1.

Figure G4-6 How TTBCR.N controls the boundary between the TTBRs, Short-descriptor format

In the selected TTBR, bits RGN, S and IRGN[1:0] define the memory region attributes for the translation table walk.

Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format describes the translation.

G4.4.5 Translation table walks, when using the VMSAv8-32 Short-descriptor translation table format

When using the Short-descriptor translation table format, and a memory access requires a translation table walk:

- A section-mapped access only requires a read of the level 1 translation table.
- A page-mapped access also requires a read of the level 2 translation table.

Reading a level 1 translation table describes how either **TTBR1** or **TTBR0** is used, with the accessed VA, to determine the address of the level1 descriptor.

Reading a level 1 translation table shows the output address as A[39:0]:

- For a Non-secure PL1&0 stage 1 translation, this is the IPA of the required descriptor. A Non-secure PL1&0 stage 2 translation of this address is performed to obtain the PA of the descriptor.
- Otherwise, this address is the PA of the required descriptor.

The full translation flow for Sections, Supersections, Small pages and Large pages on page G4-4048 then shows the complete translation flow for each valid memory access.

Reading a level 1 translation table

When performing a fetch based on **TTBR0**:

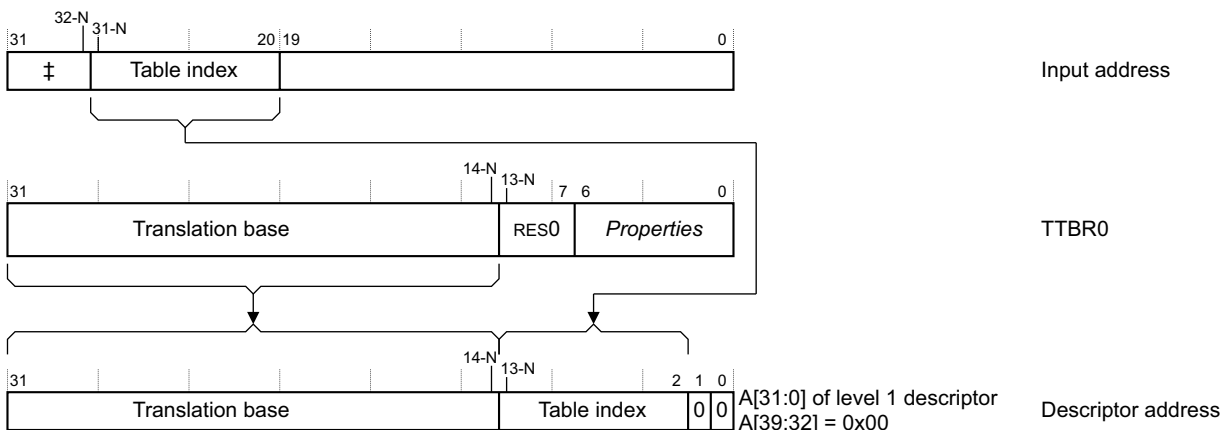

- The address bits taken from **TTBR0** vary between bits[31:14] and bits[31:7].
- The address bits taken from the VA, that is the input address for the translation, vary between bits[31:20] and bits[24:20].

The width of the **TTBR0** and VA fields depend on the value of **TTBCR.N**, as [Figure G4-7](#) shows.

When performing a fetch based on **TTBR1**, Bits **TTBR1**[31:14] are concatenated with bits[31:20] of the VA. This makes the fetch equivalent to that shown in [Figure G4-7](#), with $N=0$.

————— **Note** —————

See *The address and Properties fields shown in the translation flows* on page K7-5570 for more information about the *Properties* label used in this and other figures.

‡ This field is absent if N is 0
 N is the value of **TTBCR.N**
 For details of the *Properties* field, see the register description

Figure G4-7 Accessing level 1 translation table based on TTBR0, Short-descriptor format

Regardless of which register is used as the base for the fetch, the resulting output address selects a four-byte translation table entry that is one of:

- A level 1 descriptor for a Section or Supersection.
- A descriptor for a *Page table*, that points to a level 2 translation table. In this case:
 - A second fetch is performed to retrieve a level 2 descriptor.
 - The descriptor also contains some attributes for the access, see [Figure G4-4](#) on page G4-4042.
- A faulting entry.

The full translation flow for Sections, Supersections, Small pages and Large pages

In a translation table walk, only the initial lookup uses the translation table base address from the appropriate [TTBR](#). Subsequent lookups use a combination of address information from:

- The table descriptor read in the previous lookup.
- The input address.

Address translation examples using the VMSAv8-32 Short descriptor translation table format on page K7-5565 shows the full translation flow for each of the memory section and page options. As described in VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4041, these options are:

Supersection A 16MB memory region, see *Translation flow for a Supersection on page K7-5566*.

Section A 1MB memory region, see *Translation flow for a Section on page K7-5567*.

Large page A 64KB memory region, described by the combination of:

- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Large page.

See *Translation flow for a Large page on page K7-5568*.

Small page A 4KB memory region, described by the combination of:

- A level 1 translation table entry that indicates the address of a level 2 Page table.
- A level 2 descriptor that indicates a Small page.

See *Translation flow for a Small page on page K7-5569*.

G4.5 The VMSAv8-32 Long-descriptor translation table format

The VMSAv8-32 Long-descriptor translation table format supports the assignment of memory attributes to memory Pages, at a granularity of 4KB, across the complete input address range. It also supports the assignment of memory attributes to *blocks* of memory, where a block can be 2MB or 1GB.

———— **Note** —————

- Although the VMSAv8-32 Long-descriptor format is limited to three levels of address lookup, its design and naming conventions support extension to additional levels, to support a larger input address range.
- Similarly, while the VMSAv8-32 implementation limits the output address range to 40 bits, its design supports extension to a larger output address range.

Figure G4-2 on page G4-4027 shows the different address translation stages. The Long-descriptor translation table format:

- Is used for:
 - The Non-secure PL2 stage 1 translation.
 - The Non-secure PL1&0 stage 2 translation.
- Can be used for the Secure and Non-secure PL1&0 translations.

When used for a stage 1 translation, the translation tables support an input address of up to 32 bits, corresponding to the VA address range of the PE.

When used for a stage 2 translation, the translation tables support an input address range of up to 40 bits, to support the translation from IPA to PA. If the input address for the stage 2 translation is a 32-bit address then this address is zero-extended to 40 bits.

———— **Note** —————

When the Short-descriptor translation table format is used for the Non-secure stage 1 translations, this generates 32-bit IPAs. These are zero-extended to 40 bits to provide the input address for the stage 2 translation.

Overview of VMSAv8-32 address translation using Long-descriptor translation tables on page G4-4050 summarizes address translation from AArch32 state when using the Long-descriptor format translation tables.

The following sections then describe the format of the descriptors in the Long-descriptor format translation tables:

- *VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4050.*
- *Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4053.*
- *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4056.*

The following sections then describe this translation table format:

- *Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4057.*
- *VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4060.*
- *Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format on page G4-4063.*
- *The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format on page G4-4066.*

G4.5.1 Overview of VMSAv8-32 address translation using Long-descriptor translation tables

Figure G4-8 gives a general view of VMSAv8-32 stage 1 address translation when using the Long-descriptor translation table format.

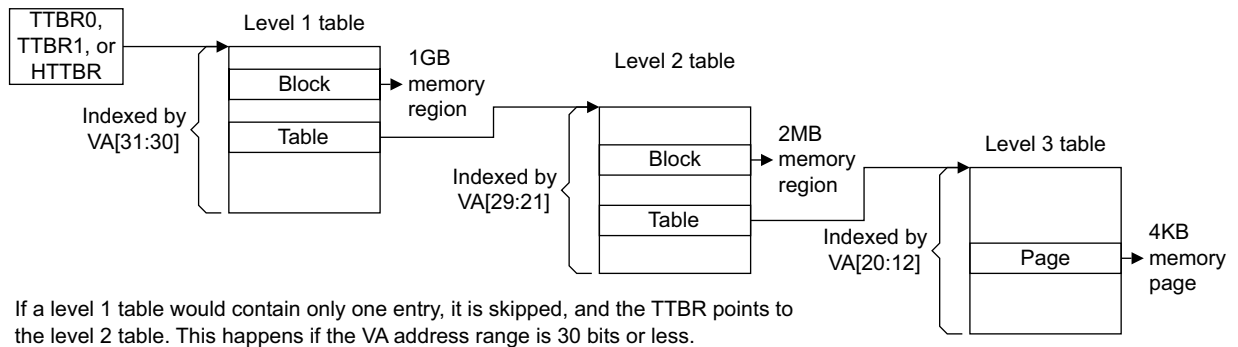

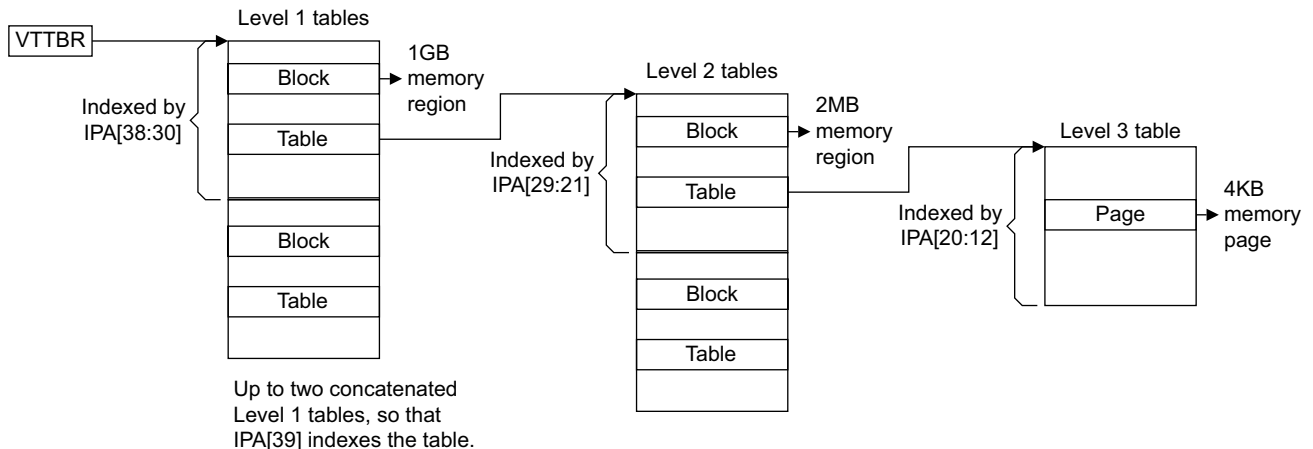

Figure G4-8 General view of VMSAv8-32 stage 1 address translation using Long-descriptor format

Figure G4-9 gives a general view of VMSAv8-32 stage 2 address translation. Stage 2 translation always uses the Long-descriptor translation table format.

If a level 1 table would contain 16 entries or fewer, level 1 lookup can be omitted. If so, VTTBR points to the start of a block of concatenated level 2 tables. See text for more information.

Figure G4-9 General view of VMSAv8-32 stage 2 address translation, Long-descriptor translation table format

Use of concatenated translation tables for the initial stage 2 lookup on page G4-4060 describes how using concatenated level 2 tables means lookup can start at level 2, as referred to in Figure G4-9.

G4.5.2 VMSAv8-32 Long-descriptor translation table format descriptors

As described in *VMSAv8-32 Long-descriptor translation table format address lookup levels* on page G4-4060, the Long-descriptor translation table format provides up to three levels of address lookup. A translation table walk starts either at level 1 or level 2 of the address lookup.

In general, a descriptor is one of:

- An invalid or fault entry.
- A table entry, that points to the next-level translation table.
- A block entry, that defines the memory properties for the access.
- A reserved format.

Bit[1] of the descriptor indicates the descriptor type, and bit[0] indicates whether the descriptor is valid.

The following sections describe the Long-descriptor translation table descriptor formats:

- [VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats.](#)
- [VMSAv8-32 Long-descriptor translation table level 3 descriptor formats on page G4-4052.](#)

[Information returned by a translation table lookup on page G4-4036](#) describes the classification of the non-address fields in the descriptors between *address map control*, *access controls*, and *region attributes*.

VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

In the Long-descriptor translation tables, the formats of the level 1 and level 2 descriptors differ only in the size of the block of memory addressed by the block descriptor. A block entry:

- In a level 1 table describes the mapping of the associated 1GB input address range.
- In a level 2 table describes the mapping of the associated 2MB input address range.

Figure G4-10 shows the Long-descriptor level 1 and level 2 descriptor formats:

For the level 1 descriptor, n is 30. For the level 2 descriptor, n is 21.

The level 1 descriptor returns the address of the level 2 table.
 The level 2 descriptor returns the address of the level 3 table.

‡ See the descriptions of the address fields for more information about bits[47:40] of the Block and Table descriptors.

Figure G4-10 VMSAv8-32 Long-descriptor level 1 and level 2 descriptor formats

Descriptor encodings, Long-descriptor level 1 and level 2 formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

- 0, Block** The descriptor gives the base address of a block of memory, and the attributes for that memory region.
- 1, Table** The descriptor gives the address of the next level of translation table, and for a stage 1 translation, some attributes for that translation.

The other fields in the valid descriptors are:

Block descriptor

Gives the base address and attributes of a block of memory:

- For a level 1 Block descriptor, bits[39:30] are bits[39:30] of the output address that specifies a 1GB block of memory.
- For a level 2 Block descriptor, bits[39:21] are bits[39:21] of the output address that specifies a 2MB block of memory.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4119](#).

Bits[63:52, 11:2] provide attributes for the target memory block, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4053](#). The position and contents of these bits is identical in the level 2 block descriptor and in the level 3 page descriptor.

Table descriptor

Bits[39:m] are bits[39:m] of the address of the required next-level table. Bits[m-1:0] of the table address are zero:

- For a level 1 Table descriptor, this is the address of a level 2 table.
- For a level 2 Table descriptor, this is the address of a level 3 table.

In both cases, if bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4119](#).

For a stage 1 translation only, bits[63:59] provide attributes for the next-level lookup, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4053](#).

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target block or table. Otherwise, it is the PA of the target block or table.

VMSAv8-32 Long-descriptor translation table level 3 descriptor formats

Each entry in a level 3 table describes the mapping of the associated 4KB input address range.

Figure G4-11 shows the Long-descriptor level 3 descriptor formats.

‡ See the description of the address field for more information about bits[47:40] of the Page descriptor.

Figure G4-11 VMSAv8-32 Long-descriptor level 3 descriptor formats

Descriptor bit[0] identifies whether the descriptor is valid, and is 1 for a valid descriptor. If a lookup returns an invalid descriptor, the associated input address is unmapped, and any attempt to access it generates a Translation fault.

Descriptor bit[1] identifies the descriptor type, and is encoded as:

0, Reserved, invalid

Behaves identically to encodings with bit[0] set to 0.

This encoding must not be used in level 3 translation tables.

1, Page Gives the address and attributes of a 4KB page of memory.

At this level, the only valid format is the Page descriptor. The other fields in the Page descriptor are:

Page descriptor

Bits[39:12] are bits[39:12] of the output address for a page of memory.

If bits[47:40] of the descriptor are not zero then a translation that uses the descriptor will generate an Address size fault, see [Address size fault on page G4-4119](#).

Bits[63:52, 11:2] provide attributes for the target memory page, see [Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors](#). The position and contents of these bits are identical in the level 1 block descriptor and in the level 2 block descriptor.

If the translation table defines the Non-secure PL1&0 stage 1 translations, then the output address in the descriptor is the IPA of the target page. Otherwise, it is the PA of the target page.

G4.5.3 Memory attribute fields in the VMSAv8-32 Long-descriptor translation table format descriptors

The memory attributes in the VMSAv8-32 Long-descriptor translation tables are based on those in the Short-descriptor translation table format, with some extensions. [Memory region attributes on page G4-4077](#) describes these attributes. In the Long-descriptor translation table format:

- Table entries for stage 1 translations define attributes for the next level of lookup, see [Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors](#)
- Block and Page entries define memory attributes for the target block or page of memory. Stage 1 and stage 2 translations have some differences in these attributes, see:
 - [Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G4-4054](#).
 - [Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors on page G4-4055](#).

Next-level attributes in VMSAv8-32 Long-descriptor stage 1 Table descriptors

In a Table descriptor for a stage 1 translation, bits[63:59] of the descriptor define the following attributes for the next-level translation table access:

- NSTable, bit[63]** For memory accesses from Secure state, specifies the Security state for subsequent levels of lookup, see [Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format on page G4-4056](#).
For memory accesses from Non-secure state, this bit is ignored.
- APTable, bits[62:61]** Access permissions limit for subsequent levels of lookup, see [Hierarchical control of access permissions, Long-descriptor format on page G4-4069](#).
APTable[0] is reserved, SBZ, in the Non-secure PL2 stage 1 translation tables.
- XNTable, bit[60]** XN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching, Long-descriptor format on page G4-4072](#).
- PXNTable, bit[59]** PXN limit for subsequent levels of lookup, see [Hierarchical control of instruction fetching, Long-descriptor format on page G4-4072](#).
This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G4-12 shows the memory attribute fields in these blocks, for a stage 1 translation:

Figure G4-12 VMSAv8-32 memory attribute fields in Long-descriptor stage 1 Block and Page descriptors

For a stage 1 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching* on page G4-4071.

PXN, bit[53] The Privileged execute-never bit. Determines whether the region is executable at EL1, see *Execute-never restrictions on instruction fetching* on page G4-4071.
 This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

Contiguous, bit[52]

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit* on page G4-4084.

nG, bit[11] The not global bit. Determines how the translation is marked in the TLB, see *Global and process-specific translation table entries* on page G4-4089.
 This bit is RES0 in the Non-secure PL2 stage 1 translation tables.

AF, bit[10] The Access flag, see *The Access flag* on page G4-4074.

SH, bits[9:8] Shareability field, see *Memory region attributes* on page G4-4077.

AP[2:1], bits[7:6]

Access Permissions bits, see *Memory access control* on page G4-4068.

Note

For consistency with the Short-descriptor translation table formats, the Long-descriptor format defines AP[2:1] as the Access Permissions bits, and does not define an AP[0] bit.

AP[1] is RES1 in the Non-secure PL2 stage 1 translation tables.

NS, bit[5] Non-secure bit. For memory accesses from Secure state, specifies whether the output address is in Secure or Non-secure memory, see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format* on page G4-4056.

For memory accesses from Non-secure state, this bit is RES0 and is ignored by the PE.

AttrIdx[2:0], bits[4:2]

Stage 1 memory attributes index field, for the indicated Memory Attribute Indirection Register, see *VMSAv8-32 Long-descriptor format memory region attributes* on page G4-4083.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see *IGNORED* on page Glossary-5718. For more information about these fields see *Other fields in the Long-descriptor translation table format descriptors* on page G4-4084.

Attribute fields in VMSAv8-32 Long-descriptor stage 2 Block and Page descriptors

Block and Page descriptors split the memory attributes into an upper block and a lower block. Figure G4-13 shows the memory attribute fields in these blocks, for a stage 2 translation:

Figure G4-13 VMSAv8-32 memory attribute fields in Long-descriptor stage 2 Block and Page descriptors

For a stage 2 descriptor, the attributes are:

XN, bit[54] The Execute-never bit. Determines whether the region is executable, see *Execute-never restrictions on instruction fetching* on page G4-4071.

Contiguous, bit[52]

Indicates that 16 adjacent translation table entries point to contiguous memory regions, see *Contiguous bit* on page G4-4084.

AF, bit[10] The Access flag, see *The Access flag* on page G4-4074.

SH, bits[9:8] Shareability field, see *EL2 control of Non-secure memory region attributes* on page G4-4085.

S2AP, bits[7:6]

Stage 2 Access Permissions bits, see *Hyp mode control of Non-secure access permissions* on page G4-4075.

Note

In the original VMSAv7-32 Long-descriptor attribute definition, this field was called HAP[2:1], for consistency with the AP[2:1] field in the stage 1 descriptors and despite there being no HAP[0] bit. ARMv8 renames the field for greater clarity.

MemAttr, bits[5:2]

Stage 2 memory attributes, see *EL2 control of Non-secure memory region attributes* on page G4-4085.

The definition of IGNORED means the architecture guarantees that the PE makes no use of the field, see *IGNORED* on page Glossary-5718. For more information about these fields see *Other fields in the Long-descriptor translation table format descriptors* on page G4-4084.

G4.5.4 Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format

[Access to the Secure or Non-secure physical address map on page G4-4038](#) describes how the NS bit in the translation table entries:

- For accesses from Secure state, determines whether the access is to Secure or Non-secure memory.
- Is ignored by accesses from Non-secure state.

In the Long-descriptor format:

- The NS bit relates only to the memory block or page at the output address defined by the descriptor.
- The descriptors also include an NSTable bit, see [Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format](#).

The NS and NSTable bits are valid only for memory accesses from Secure state. Memory accesses from Non-secure state ignore the values of these bits.

Hierarchical control of Secure or Non-secure memory accesses, Long-descriptor format

For Long-descriptor format table descriptors for stage 1 translations, the descriptor includes an NSTable bit, that indicates whether the table identified in the descriptor is in Secure or Non-secure memory. For accesses from Secure state, the meaning of the NSTable bit is:

NSTable == 0 The defined table address is in the Secure physical address space. In the descriptors in that translation table, NS bits and NSTable bits have their defined meanings.

NSTable == 1 The defined table address is in the Non-secure physical address space. Because this table is fetched from the Non-secure address space, the NS and NSTable bits in the descriptors in this table must be ignored. This means that, for this table:

- The value of the NS bit in any block or page descriptor is ignored. The block or page address refers to Non-secure memory.
- The value of the NSTable bit in any table descriptor is ignored, and the table address refers to Non-secure memory. When this table is accessed, the NS bit in any block or page descriptor is ignored, and all descriptors in the table refer to Non-secure memory.

In addition, an entry fetched in Secure state is treated as non-global if it is read from Non-secure memory. That is, these entries must be treated as if $nG==1$, regardless of the value of the nG bit. For more information about the nG bit, see [Global and process-specific translation table entries on page G4-4089](#).

The effect of NSTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to NSTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

————— Note —————

- When using the Long-descriptor format, table descriptors are defined only for the level 1 and level 2 of lookup.
 - Stage 2 translations are performed only for operations in Non-secure state, that can access only the Non-secure address space. Therefore, the stage 2 descriptors do not include NS or NSTable bits.
-

G4.5.5 Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format

As described in *Determining the translation table base address in the VMSAv8-32 translation regimes* on page G4-4037, two sets of translation tables can be defined for each of the PL1&0 stage 1 translations, and **TTBR0** and **TTBR1** hold the base addresses for the two sets of tables. The Long-descriptor translation table format provides more flexibility in defining the boundary between using **TTBR0** and using **TTBR1**. When a PL1&0 stage 1 address translation is enabled, **TTBR0** is always used. If **TTBR1** is also used then:

- **TTBR1** is used for the top part of the input address range.
- **TTBR0** is used for the bottom part of the input address range.

The **TTBCR.T0SZ** and **TTBCR.T1SZ** size fields control the use of **TTBR0** and **TTBR1**, as Table G4-2 shows.

Table G4-2 Use of TTBR0 and TTBR1, Long-descriptor format

| TTBCR | | Input address range using: | |
|-------|-------|------------------------------|---|
| T0SZ | T1SZ | TTBR0 | TTBR1 |
| 0b000 | 0b000 | All addresses | Not used |
| M^a | 0b000 | Zero to $(2^{(32-M)}-1)$ | 2^{32-M} to maximum input address |
| 0b000 | N^a | Zero to $(2^{32-2(32-N)}-1)$ | $2^{32-2(32-N)}$ to maximum input address |
| M^a | N^a | Zero to $(2^{(32-M)}-1)$ | $2^{32-2(32-N)}$ to maximum input address |

a. M, N must be greater than 0. The maximum possible value for each of **T0SZ** and **T1SZ** is 7.

For stage 1 translations, the input address is always a VA, and the maximum possible VA is $(2^{32}-1)$.

When address translation is using the Long-descriptor translation table format:

- Figure G4-14 shows how, when **TTBCR.T1SZ** is zero, the value of **TTBCR.T0SZ** controls the boundary between VAs that are translated using **TTBR0**, and VAs that are translated using **TTBR1**.

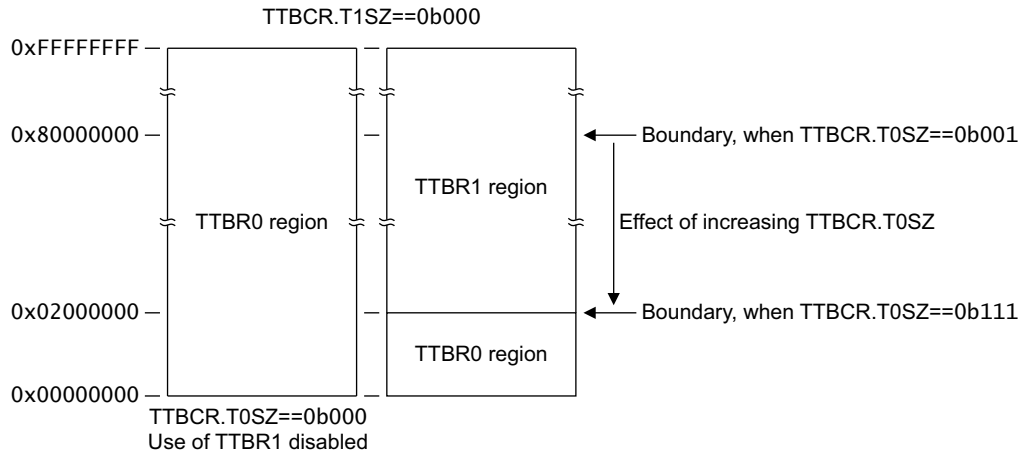

Figure G4-14 Control of TTBR boundary, when TTBCR.T1SZ is zero

- [Figure G4-15](#) shows how, when `TTBCR.T1SZ` is nonzero, the values of `TTBCR.T0SZ` and `TTBCR.T1SZ` control the boundaries between VAs that are translated using `TTBR0`, and VAs that are translated using `TTBR1`.

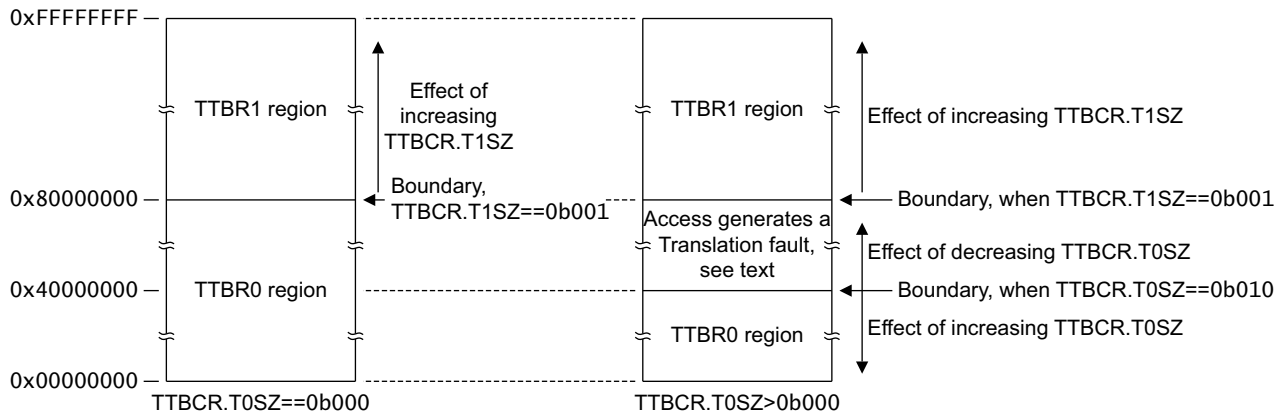

Figure G4-15 Control of TTBR boundaries, when `TTBCR.T1SZ` is nonzero

When `T0SZ` and `T1SZ` are both nonzero:

- If both fields are set to `0b001`, the boundary between the two regions is `0x80000000`. This is identical to having `T0SZ` set to `0b000` and `T1SZ` set to `0b001`.
- Otherwise, the `TTBR0` and `TTBR1` regions are non-contiguous. In this case, any attempt to access an address that is in that gap between the `TTBR0` and `TTBR1` regions generates a Translation fault.

Note

The handling of the Contiguous bit can mean that the boundary between the translation regions defined by the `TCR_EL1.TnSZ` values and the region for which an access generates a Translation fault is wider than shown in [Figure G4-15](#). That is, if the descriptor for an access to the region shown as generating a fault has the Contiguous bit set to 1, the access might not generate a fault. [Possible translation table registers programming errors](#) describes this possibility.

When using the Long-descriptor translation table format:

- The `TTBCR` contains fields that define memory region attributes for the translation table walk, for each `TTBR`. These are the `SH0`, `ORGN0`, `IRGN0`, `SH1`, `ORGN1`, and `IRGN1` bits.
- `TTBR0` and `TTBR1` each contain an ASID field, and the `TTBCR.A1` field selects which ASID to use.

For this translation table format, [VMSAv8-32 Long-descriptor translation table format address lookup levels](#) on page G4-4060 summarizes the lookup levels, and [Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format](#) on page G4-4063 describes the possible translations.

Possible translation table registers programming errors

In all the descriptions in this subsection, the *size of the input address* supported for a PL1&0 stage 1 translation refers to the size specified by a `TTBCR.TxSZ` field.

Note

For a PL1&0 stage 1 translation, this section has described how the input address range can be split so that the lower addresses are translated by `TTBR0` and the higher addresses are translated by `TTBR1`. In this case, each of input address sizes specified by `TTBCR.{T0SZ, T1SZ}` is smaller than the total address size supported by the stage of translation.

The following are possible errors in the programming of **TTBR0**, **TTBR1**, and **TTBCR**. For the translation of a particular address at a particular stage of translation, either:

- The block size being used to translate the address is larger than the size of the input address supported at a stage of translation used in performing the required translation. This can occur only for the PL1&0 stage 1 translations, and only when either **TTBCR.T0SZ** or **TTBCR.T1SZ** is zero, meaning there is no gap between the address range translated by **TTBR0** and the range translated by **TTBR1**. In this case, this programming error occurs if a block translated from the region that has **TxSZ** set to zero straddles the boundary between the two address ranges. [Example G4-2](#) shows an example of this mis-programming.
- The address range translated by a set of blocks marked as contiguous, by use of the contiguous bit, is larger than the size of the input address supported at a stage of translation used in performing the required translation.

Example G4-2 Translation table programming error

If **TTBCR.T0SZ** is programmed to 0 and **TTBCR.T1SZ** is programmed to 7, this means:

- **TTBR0** translates addresses in the range 0x00000000-0xFDFFFFFF.
- **TTBR1** translates addresses in the range 0xFE000000-0xFFFFFFFF.

The translation table indicated by **TTBR0** might be programmed with a block entry for a 1GB region starting at 0xC0000000. This covers the address range 0xC0000000-0xFFFFFFFF, that overlaps the **TTBR1** address range. This means this block size is larger than the input address size supported for translations using **TTBR0**, and therefore this is a programming error.

To understand why this must be a programming error, consider a memory access to address 0xFFFF0000. According to the **TTBCR.{T0SZ, T1SZ}** values, this must be translated using **TTBR1**. However, the access matches a TLB entry for the translation, using **TTBR0**, of the block at 0xC0000000. Hardware is not required to detect that the access to 0xFFFF0000 is being translated incorrectly.

In these cases, an implementation might use one of the following approaches:

- Treat such a block, that might be a block within a contiguous set of blocks, as causing a Translation fault, even though the block is valid, and the address accessed within that block is within the size of the input address supported at a stage of translation.
- Treat such a block, that might be a block within a contiguous set of blocks, as not causing a Translation fault, even though the address accessed within that block is outside the size of the input address supported at a stage of translation, provided that both of the following apply:
 - The block is valid.
 - At least one address within the block, or contiguous set of blocks, is within the size of the input address supported at a stage of translation.

Additional constraints apply to programming the **VTCR**, see [Determining the required initial lookup level for stage 2 translations on page G4-4065](#).

G4.5.6 VMSAv8-32 Long-descriptor translation table format address lookup levels

As stated at the start of this section, because the Long-descriptor translation table format is used for the Non-secure PL1&0 stage 2 translations, the format must support input addresses of up to 40 bits.

Table G4-3 summarizes the properties of the different levels of address lookup when using this format.

Table G4-3 Properties of the three levels of address lookup with VMSAv8-32 Long-descriptor translation tables

| Level | Input address | | Output address ^a | | Number of entries |
|--------|---------------|----------------------------|-----------------------------|----------------|-------------------|
| | Size | Address range ^b | Size | Address range | |
| First | Up to 512GB | Up to Address[38:0] | 1GB | Address[39:30] | Up to 512 |
| Second | Up to 1GB | Up to Address[29:0] | 2MB | Address[39:21] | Up to 512 |
| Third | 2MB | Address[20:0] | 4KB | Address[39:12] | 512 |

a. Output address when an entry addresses a block of memory or a memory page. If an entry addresses the next level of address lookup it specifies Address[39:12] for the next-level translation table.

b. Input address range for the translation table. See *Use of concatenated level 1 translation tables* on page G4-4061 for details of support for additional bits of address at a given level, including possible support of a 40-bit input address range for stage 2 translations at level 1. For stage 1 translations at level 1 the input address range is limited to the VA size of [31:0].

For level 1 and level 2 tables, reducing the input address range reduces the number of addresses in the table and therefore reduces the table size. The appropriate Translation Table Control Register specifies the input address range.

Stage 1 translations require an input address range of up to 32 bits, corresponding to VA[31:0]. For these translations:

- For a memory access from a mode other than Hyp mode, the Secure or Non-secure **TTBR0** or **TTBR1** holds the translation table base address, and the Secure or Non-secure **TTBCR** is the control register.
- For a memory access from Hyp mode, **HTTBR** holds the translation table base address, and **HTCR** is the control register.

Note

For translations controlled by **TTBR0** and **TTBR1**, if neither **TTBR** has an input address range larger than 1GB, then translation starts at level 2. Together, **TTBR0** and **TTBR1** can still cover the 32-bit VA input address range.

Stage 2 translations require an input address range of up to 40 bits, corresponding to IPA[39:0], and the supported input address size is configurable in the range 25-40 bits. Table G4-3 indicates a requirement for the translation mechanism to support a 39-bit input address range, Address[38:0]. *Use of concatenated translation tables for the initial stage 2 lookup* describes how a 40-bit IPA address range is supported. For stage 2 translations:

- **VTTBR** holds the translation table base address, and **VTTCR** is the control register.
- If a supplied input address is larger than the configured input address size, a Translation fault is generated.

Use of concatenated translation tables for the initial stage 2 lookup

If a stage 2 translation would require 16 entries or fewer in its top-level translation table, that stage of translation can, instead, be configured so that:

- It requires the corresponding number of concatenated translation tables at the next translation level, aligned to the size of the block of concatenated translation tables.
- The stage 2 translation starts at that next translation level.

Note

Stage 2 translations always use the Long-descriptor translation table format.

This use of concatenated translation tables is:

- Required when the stage 2 translation supports a 40-bit input address range, see [Use of concatenated level 1 translation tables](#).
- Supported for a stage 2 translation with an input address range of 31-34 bits, see [Use of concatenated level 2 translation tables](#).

The use of concatenated translation tables requires the software that is defining the translation to:

- Define the concatenated translation tables with the required overall alignment.
- Program [VTTBR](#) to hold the address of the first of the concatenated translation tables.
- Program [VTCR](#) to indicate the required input address range and initial lookup level.

Note

The use of concatenated translation tables avoids the overhead of an additional level of translation

Use of concatenated level 1 translation tables

The Long-descriptor format translation tables provide 9 bits of address resolution at each level of lookup. However, a 40-bit input address range with a translation granularity of 4KB requires a total of 28 bits of address resolution. Therefore, a stage 2 translation that supports a 40-bit input address range requires two concatenated level 1 translation tables, together aligned to 8KB, where:

- The table at the address with $PA[12:0] == 0b0_0000_0000_0000$ defines the translations for input addresses with $bit[39] == 0$.
- The table at the address with $PA[12:0] == 0b1_0000_0000_0000$ defines the translations for input addresses with $bit[39] == 1$.
- The 8KB alignment requirement means that both tables have the same value for $PA[39:13]$.

Use of concatenated level 2 translation tables

A stage 2 translation with an input address range of 31-34 bits can start the translation either:

- With a level 1 lookup, accessing a level 1 translation table with 2-16 entries.
- With a level 2 lookup, accessing a set of concatenated level 2 translation tables.

[Table G4-4 on page G4-4062](#) shows these options, for each of the input address ranges that can use this scheme.

Note

Because these are stage 2 translations, the input address range is an IPA range.

Table G4-4 Possible uses of concatenated translation tables for level 2 lookup

| Input address range | | Lookup starts at level 1 | Lookup starts at level 2 | |
|---------------------|-----------------------|--------------------------|-------------------------------|---------------------------------|
| IPA range | Size | Required level 1 entries | Number of concatenated tables | Required alignment ^a |
| IPA[30:0] | 2 ³¹ bytes | 2 | 2 | 8KB |
| IPA[31:0] | 2 ³² bytes | 4 | 4 | 16KB |
| IPA[32:0] | 2 ³³ bytes | 8 | 8 | 32KB |
| IPA[33:0] | 2 ³⁴ bytes | 16 | 16 | 64KB |

a. Required alignment of the set of concatenated level 2 tables.

See also [Determining the required initial lookup level for stage 2 translations](#) on page G4-4065.

G4.5.7 Translation table walks, when using the VMSAv8-32 Long-descriptor translation table format

Figure G4-2 on page G4-4027 shows the possible address translations. If a stage of translation is controlled from an Exception level that is using AArch32, the input and output address constraints and the registers that control the translation are as follows:

Stage 1 translations

For all stage 1 translations:

- The input address range is up to 32 bits, as determined by either:
 - **TTBCR.T0SZ** or **TTBCR.T1SZ**, for a PL1&0 stage 1 translation.
 - **HTCR.T0SZ**, for a PL2 stage 1 translation.
- The output address range is 40 bits.

The stage 1 translations are:

Non-secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Non-secure modes other than Hyp mode. This translates a VA to an IPA. For this translation, when Non-secure EL1 is using AArch32:

- Non-secure **TTBR0** or **TTBR1** holds the translation table base address.
- Non-secure **TTBCR** determines which TTBR is used.

Non-secure PL2 stage 1 translation

The stage 1 translation for memory accesses from Hyp mode, translates a VA to a PA. For this translation, when EL2 is using AArch32, **HTTBR** holds the translation table base address.

Secure PL1&0 stage 1 translation

The stage 1 translation for memory accesses from Secure modes, translates a VA to a PA. For this translation, when the Secure PL1 modes are using AArch32:

- Secure **TTBR0** or **TTBR1** holds the translation table base address.
- Secure **TTBCR** determines which TTBR is used.

Stage 2 translation

Non-secure PL1&0 stage 2 translation

The stage 2 translation for memory accesses from Non-secure modes other than Hyp mode, and translates an IPA to a PA. For this translation, when EL2 is using AArch32:

- The input address range is 40 bits, and **VTCR.T0SZ** determines the input address size.
- The output address range depends on the implemented memory system, and is up to 40 bits.
- **VTTBR** holds the translation table base address.
- **VTCR** specifies the required input address range, and whether the initial lookup is at level 1 or at level 2.

The descriptions of the VMSAv8-32 translation stages state that the maximum output address size is 40 bits. However, the register and Long-descriptor format descriptor fields that hold these addresses are 48 bits wide. If bits[47:40] of an output address are not all zero then the address generates an Address size fault.

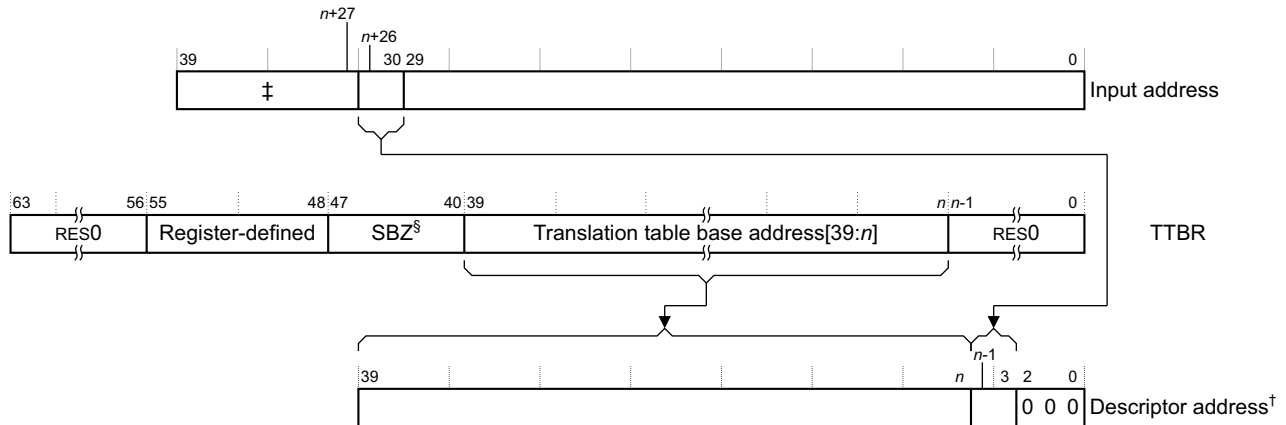

The Long-descriptor translation table format provides up to three levels of address lookup, as described in [VMSAv8-32 Long-descriptor translation table format address lookup levels on page G4-4060](#), and the initial lookup, in which the MMU reads the translation table base address, is at either level 1 or level 2. The following determines the level of the initial lookup:

- For a stage 1 translation, the required input address range. For more information see [Determining the required initial lookup level for stage 1 translations on page G4-4065](#).
- For a stage 2 translation, the level specified by the **VTCR.SL0** field. For more information see [Determining the required initial lookup level for stage 2 translations on page G4-4065](#).

————— **Note** —————

For a stage 2 translation, the size of the required input address range constrains the **VTCCR.SL0** value.

Figure G4-16 shows how the descriptor address for the initial lookup for a translation using the Long-descriptor translation table format is determined from the input address and the **TTBR** value. This figure shows the lookup for a translation that starts with a level 1 lookup, that translates bits[39:30] of the input address, zero extended if necessary.

See text for more information about the translation table base register used, and the value of n .

‡ This field is absent if n is 13.

† For a Non-secure PL1&0 stage 1 translation, the IPA of the descriptor. Otherwise, the PA of the descriptor.

§ See the lookup description for more information about bits[40:47] of the TTBR

Figure G4-16 VMSAv8-32 Long-descriptor initial lookup, starting at level 1

If bits[47:40] of the **TTBR** are not zero then the initial lookup will generate an Address size fault, see [Address size fault on page G4-4119](#).

For a translation that starts with a level 1 lookup, as shown in [Figure G4-16](#):

For a stage 1 translation

n is in the range 4-5 and:

- For a memory access from Hyp mode:
 - **HTTBR** is the **TTBR**.
 - $n=5-(\text{HTCR.TOSZ})$.
- For other accesses:
 - The Secure or Non-secure instance of **TTBR0** or **TTBR1** is the **TTBR**.
 - $n=(5-\text{TTBCR.TxSZ})$, where x is 0 when using **TTBR0**, and 1 when using **TTBR1**.

For a stage 2 translation

n is in the range 4-13 and:

- **VTTBR** is the **TTBR**.
- $n=5-(\text{VTCCR.TOSZ})$.

For a translation that starts with a level 2 lookup, the descriptor address is obtained in the same way, except that bits[(n+17):21] of the input address provide bits[(n-1):3] of the descriptor address, where:

For a stage 1 translation

n is in the range 7-12. As [Determining the required initial lookup level for stage 1 translations](#) shows, for a stage 1 translation to start with a level 2 lookup, the corresponding T0SZ or T1SZ field must be 2 or more. This means:

- For a memory access from Hyp mode, $n=14-HTCR.T0SZ$.
- For other memory accesses, $n=14-(TTBCR.TxSZ)$, where *x* is 0 when using **TTBR0**, and 1 when using **TTBR1**.

For a stage 2 translation

n is in the range 7-16. For a stage 2 translation to start with a level 2 lookup, **VTCR.SL0** is 0b00, and $n=14-(VTCR.T0SZ)$.

The following sections describe how the level of the initial lookup is determined:

- [Determining the required initial lookup level for stage 1 translations.](#)
- [Determining the required initial lookup level for stage 2 translations.](#)

[Address translation examples using the VMSAv8-32 Long descriptor translation table format on page K7-5570](#) shows examples of full translation flows, to an entry for a 4KB memory page, for lookups starting at level 1 and lookups starting at level 2.

Determining the required initial lookup level for stage 1 translations

For a stage 1 translation, the required input address range, indicated by a T0SZ or T1SZ field in a translation table control register, determines the initial lookup level. The size of this input address region is $2^{(32-TxSZ)}$ bytes, and if this size is:

- Less than or equal to 2^{30} bytes, the required start is at level 2, and translation requires two levels of table to map to 4KB pages. This corresponds to a TxSZ value of 2 or more.
- More than 2^{30} bytes, the required start is at level 1, and translation requires three levels of table to map to 4KB pages. This corresponds to a TxSZ value that is less than 2.

For the PL1&0 stage 1 translations, the **TTBCR**:

- Splits the 32-bit VA input address range between **TTBR0** and **TTBR1**, see [Selecting between TTBR0 and TTBR1, VMSAv8-32 Long-descriptor translation table format on page G4-4057](#).
- Holds the input address range sizes for **TTBR0** and **TTBR1**, in the **TTBCR.T0SZ** and **TTBCR.T1SZ** fields.

For the PL2 stage 1 translations, **HTCR.T0SZ** indicates the size of the required input address range. For example, if this field is 0b000, it indicates a 32-bit VA input address range, and translation lookup must start at level 1.

Determining the required initial lookup level for stage 2 translations

For a PL1&0 stage 2 translation, the output address range from the PL1&0 stage 1 translations determines the required input address range for the stage 2 translation.

VTCR.SL0 indicates the starting level for the lookup. The permitted SL0 values are:

- 0b00 Stage 2 translation lookup must start at level 2.
- 0b01 Stage 2 translation lookup must start at level 1.

In addition, **VTCR.T0SZ** must indicate the required input address range. The size of the input address region is $2^{(32-T0SZ)}$ bytes.

———— **Note** —————

VTCR.TOSZ holds a four-bit signed integer value, meaning it supports values from -8 to 7. This is different from the other translation control registers, where **TnSZ** holds a three-bit unsigned integer, supporting values from 0 to 7.

The programming of **VTCR** must follow the constraints shown in [Table G4-5](#), otherwise any attempt to perform a translation table walk that uses the stage 2 address translation generates a stage 2 level 1 Translation Fault. The table also shows how the **VTCR.SL0** and **VTCR.TOSZ** values determine the **VTBTR.BADDR** field width.

———— **Note** —————

If **VTCR.SL0** is programmed to a reserved value then the constraints shown in [Table G4-5](#) are not met, and a translation table walk that uses stage 2 translation generates a stage 2 level 1 Translation fault.

Table G4-5 Input address range constraints on programming **VTCR**

| VTCR.SL0 | VTCR.TOSZ | Input address range, R | Initial lookup level | BADDR[39:x] width^a |
|-----------------|------------------|--------------------------------|-----------------------------|--------------------------------------|
| 0b00 | 2 to 7 | $R \leq 2^{30}$ bytes | Level 2 | [39:12] to [39:7] |
| 0b00 | -2 to 1 | $2^{30} < R \leq 2^{34}$ bytes | Level 2 | [39:16] to [39:13] |
| 0b01 | -2 to 1 | | Level 1 | [39:7] to [39:4] |
| 0b01 | -8 to -3 | $2^{34} < R$ | Level 1 | [39:13] to [39:8] |

a. The first range corresponds to the first TOSZ value, the second range to the second TOSZ value.

In addition, **VTCR.S** must be programmed to the value of **TOSZ[3]**, otherwise behavior is **CONSTRAINED UNPREDICTABLE** with the resulting behavior being that **VTCR.TOSZ** is treated as an **UNKNOWN** value.

———— **Note** —————

VTCR.TOSZ being treated as an **UNKNOWN** value results in a stage 2 level 1 Translation Fault if that **UNKNOWN** value is not consistent with the programmed value of **VTCR.SL0**.

*CONSTRAINED UNPREDICTABLE behaviors associated with the **VTCR** on page K1-5474* describes these **CONSTRAINED UNPREDICTABLE** behaviors.

Where necessary, the initial lookup level provides multiple concatenated translation tables, as described in *Use of concatenated level 2 translation tables on page G4-4061*. This section also gives more information about the alternatives, shown in [Table G4-5](#), when **R** is in the range $2^{31} - 2^{34}$.

G4.5.8 The algorithm for finding the translation table entries, VMSAv8-32 Long-descriptor format

This section gives the algorithm for finding the translation table entry that corresponds to a given IA, for each required level of lookup. The algorithm encodes the descriptions of address translation given earlier in this section. The VMSAv8-32 Long-descriptor format uses a 4KB translation granule.

The description uses the following terms:

- BaseAddr** The base address for the level of lookup, as defined by:
- For the initial lookup level, the **TTBR.BADDR** base address field in the appropriate **TTBR**, see the description of *TnSZ* on page G4-4067.
 - Otherwise, the translation table address returned by the previous level of lookup.
- IA** The supplied IA for this stage of translation.

- TnSZ** The translation table size for this stage of translation:
- For PL1&0 stage 1** Either:
- **TTBCR.T0SZ** if the translation is using **TTBR0**.
 - **TTBCR.T1SZ** if the translation is using **TTBR1**.
- For PL1&0 stage 2** **VTCR.T0SZ**. The translation uses **VTTBR**.
- For PL2 stage 1** **HTCR.T0SZ**. The translation uses **HTTBR**.
- SL0** **VTCR.SL0**. Applies to the Non-secure PL1&0 stage 2 translation only.

Table G4-6 shows the translation table descriptor address, for each level of lookup. The table shows only architecturally-valid programming of the **TCR**. See also *Possible translation table registers programming errors on page G4-4058*.

Table G4-6 Translation table entry addresses, VMSAv8-32 using Long-descriptor format

| Lookup level | Entry address and conditions | | General conditions |
|--------------|--|--|--------------------|
| | Stage 1 translation | Stage 2 translation | |
| One | BaseAddr[39:x]:IA[y:30]:0b000 if ^a $0 \leq TnSZ \leq 1$ then $x = (5 - TnSZ)$ | BaseAddr[39:x]:IA[y:30]:0b000 if $SL0^b == 1$ then if ^a $-8 \leq T0SZ \leq 1$ then $x = (5 - T0SZ)$ | $y = (x + 26)$ |
| Two | BaseAddr[39:x]:IA[y:21]:0b000 if ^a $2 \leq TnSZ \leq 7$ then $x = (14 - TnSZ)$ else ^c $x = 12$ | BaseAddr[39:x]:IA[y:21]:0b000 if $SL0 == 0$ then if ^a $-2 \leq T0SZ \leq 7$ then $x = (14 - T0SZ)$ elsif ^c $SL0^b == 1$ then $x = 12$ | $y = (x + 17)$ |
| Three | BaseAddr[39:12]:IA[20:12]:0b000 | BaseAddr[39:12]:IA[20:12]:0b000 | - |

- a. This line indicates the range of permitted values for **TnSZ**, for a lookup that starts at this level, see *Use of concatenated translation tables for the initial stage 2 lookup on page G4-4060*.
- b. $SL0 == 0$ if the initial lookup is level 2, $SL0 == 1$ if the initial lookup is level 1.
- c. This is the case where this level of lookup is not the initial level of lookup.

G4.6 Memory access control

In addition to an output address, a translation table entry that refers to page or region of memory includes fields that define properties of the target memory region. [Information returned by a translation table lookup on page G4-4036](#) describes the classification of those fields as address map control, access control, and memory attribute fields. The access control fields, described in this section, determine whether the PE, in its current state, is permitted to perform the required access to the output address given in the translation table descriptor. If a translation stage does not permit the access then an MMU fault is generated for that translation stage, and no memory access is performed.

The following sections describe the memory access controls:

- [Access permissions.](#)
- [Execute-never restrictions on instruction fetching on page G4-4071.](#)
- [Domains, Short-descriptor format only on page G4-4073.](#)
- [The Access flag on page G4-4074.](#)
- [Hyp mode control of Non-secure access permissions on page G4-4075.](#)

G4.6.1 Access permissions

———— Note ————

This section gives a general description of memory access permissions. Software executing at PL1 in Non-secure state can see only the access permissions defined by the Non-secure PL1&0 stage 1 translations. However, software executing at PL2 can modify these permissions, as described in [Hyp mode control of Non-secure access permissions on page G4-4075](#). This modification is invisible to Non-secure software executing at EL1 or EL0.

Access permission bits in a translation table descriptor control access to the corresponding memory region. The details of this control depend on the translation table format, as follows:

Short-descriptor format

This format supports two options for defining the access permissions:

- Three bits, AP[2:0], define the access permissions.
- Two bits, AP[2:1], define the access permissions, and AP[0] can be used as an Access flag.

[SCTLR.AFE](#) selects the access permissions option. Setting this bit to 1, to enable the Access flag, also selects use of AP[2:1] to define access permissions.

ARM deprecates any use of the AP[2:0] scheme for defining access permissions.

Long-descriptor format

AP[2:1] to control the access permissions, and the descriptors provide an AF bit for use as an Access flag. This means VMSAv8-32 behaves as if the value of [SCTLR.AFE](#) is 1, regardless of the value that software has written to this bit.

———— Note ————

When use of the Long-descriptor format is enabled, [SCTLR.AFE](#) is UNK/SBOP.

[The Access flag on page G4-4074](#) describes the Access flag, for both translation table formats.

The XN and PXN bits provide additional access controls for instruction fetches, see [Execute-never restrictions on instruction fetching on page G4-4071](#).

An attempt to perform a memory access that the translation table access permission bits do not permit generates a Permission fault, for the corresponding stage of translation. However, when using the Short-descriptor translation table format, it generates the fault only if the access is to memory in the Client domain, see [Domains, Short-descriptor format only on page G4-4073](#).

———— **Note** —————

For the Non-secure PL1&0 translation regime, memory accesses are subject to two stages of translation. Each stage of translation has its own, independent, fault checking. Fault handling is different for the two stages, see [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#).

The following sections describe the two access permissions models:

- [AP\[2:1\] access permissions model](#).
- [AP\[2:0\] access permissions control, Short-descriptor format only on page G4-4070](#). This section includes some information on access permission control in earlier versions of the ARM VMSA.

AP[2:1] access permissions model

———— **Note** —————

ARM recommends that this model is always used, even where the AP[2:0] model is permitted. Some documentation describes the AP[2:1] model as the *simplified access permissions* model.

This access permissions model is used if the translation is either:

- Using the Long-descriptor translation table format.
- Using Short-descriptor translation table format, and the [SCTLR.AFE](#) bit is set to 1.

In this model:

- One bit, AP[2], selects between read-only and read/write access.
- A second bit, AP[1], selects between Application level (PL0) and System level (PL1) control. For the Non-secure PL2 stage 1 translations, AP[1] is SBO.

This provides four access combinations:

- Read-only at all privilege levels.
- Read/write at all privilege levels.
- Read-only at PL1, no access by software executing at PL0.
- Read/write at PL1, no access by software executing at PL0.

[Table G4-7](#) shows this access control model.

Table G4-7 VMSAv8-32 AP[2:1] access permissions model

| AP[2], disable write access | AP[1], enable unprivileged access | Access |
|-----------------------------|-----------------------------------|------------------------------------|
| 0 | 0 ^a | Read/write, only at PL1 |
| 0 | 1 | Read/write, at any privilege level |
| 1 | 0 ^a | Read-only, only at PL1 |
| 1 | 1 | Read-only, at any privilege level |

a. Not valid for Non-secure PL2 stage 1 translation tables. AP[1] is SBO in these tables.

Hierarchical control of access permissions, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that entries at one level of translation table lookup can use to set limits on the permitted entries at subsequent levels of lookup. This applies to the access permissions, and also to the restrictions on instruction fetching described in [Hierarchical control of instruction fetching, Long-descriptor format on page G4-4072](#).

The restrictions apply only to subsequent levels of lookup at the same stage of translation. The APTable[1:0] field restricts the access permissions, as [Table G4-8 on page G4-4070](#) shows.

As stated in the table footnote, for the Non-secure PL2 stage 1 translation tables, APTable[0] is reserved, SBZ.

Table G4-8 Effect of APTable[1:0] on subsequent levels of lookup

| APTable[1:0] | Effect |
|-----------------|--|
| 00 | No effect on permissions in subsequent levels of lookup. |
| 01 ^a | Access at PL0 not permitted, regardless of permissions in subsequent levels of lookup. |
| 10 | Write access not permitted, at any exception level, regardless of permissions in subsequent levels of lookup. |
| 11 ^a | Regardless of permissions in subsequent levels of lookup: <ul style="list-style-type: none"> • Write access not permitted, at any exception level. • Read access not permitted at PL0. |

a. Not valid for the Non-secure PL2 stage 1 translation tables. In those tables, APTable[0] is SBZ.

Note

The APTable[1:0] settings are combined with the translation table access permissions in the translation tables descriptors accessed in subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The Long-descriptor format provides APTable[1:0] control only for the stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of APTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to APTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

AP[2:0] access permissions control, Short-descriptor format only

This access permissions model applies when using the Short-descriptor translation tables format, and the SCTLRAFE bit is set to 0. ARM deprecates any use of this access permissions model.

When SCTLRAFE is set to 0, ensuring that the AP[0] bit is always set to 1 effectively changes the access model to the simpler model described in *AP[2:1] access permissions model on page G4-4069*.

Table G4-9 shows the full AP[2:0] access permissions model:

Table G4-9 VMSAv8-32 MMU access permissions

| AP[2] | AP[1:0] | PL1 access | Unprivileged access | Description |
|-------|---------|------------|---------------------|---|
| 0 | 00 | No access | No access | All accesses generate Permission faults |
| | 01 | Read/write | No access | Access only at PL1 |
| | 10 | Read/write | Read-only | Writes at PL0 generate Permission faults |
| | 11 | Read/write | Read/write | Full access |
| 1 | 00 | - | - | Reserved |
| | 01 | Read-only | No access | Read-only, only at PL1 |
| | 10 | Read-only | Read-only | Read-only at any exception level, deprecated ^a |
| | 11 | Read-only | Read-only | Read-only at any exception level ^b |

a. From VMSAv7, ARM strongly recommends use of the 0b11 encoding for Read-only at any exception level.

b. This mapping was introduced in VMSAv7, and is reserved in earlier versions of the VMSA.

———— **Note** ————

- VMSAv8-32 supports the full set of access permissions shown in [Table G4-9 on page G4-4070](#) only when `SCTLR.AFE` is set to 0. When `SCTLR.AFE` is set to 1, the only supported access permissions are those described in [AP\[2:1\] access permissions model on page G4-4069](#).
- Some old documentation describes the AP[2] bit in the translation table entries as the APX bit.

G4.6.2 Execute-never restrictions on instruction fetching

Execute-never (XN) controls provide an additional level of control on memory accesses permitted by the access permissions settings. These controls are:

XN, Execute-never

When the XN bit is 1, a Permission fault is generated if the PE attempts to execute an instruction from the corresponding memory region. However, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain, see [Domains, Short-descriptor format only on page G4-4073](#). A PE can execute instructions from a memory region only if the access permissions for its current state permit read access, and the value of the XN bit is 0.

PXN, Privileged execute-never

When the PXN bit is 1, a Permission fault is generated if the PE is executing at PL1 and attempts to execute an instruction from the corresponding memory region. As with the XN bit, when using the Short-descriptor translation table format, the fault is generated only if the access is to memory in the Client domain.

In both the Short-descriptor format and the Long-descriptor format translation tables, all descriptors for memory blocks and pages always include an XN bit.

Support for the PXN bit is as follows:

- The Long-descriptor translation table formats always include the PXN bit. However, in the Non-secure PL2 stage 1 translation tables, and in the Non-secure PL1&0 stage 2 translation tables, the PXN bit is reserved, SBZ.
- All implementations must:
 - Support the use of the PXN bit in the PL1&0 translation regime.
 - Use the Short-descriptor translation table formats that include the PXN bit.

In the Non-secure PL1&0 translation regime, a region is execute-never if the value of the XN bit is 1 in one or both of the stage 1 translation table descriptor and the stage 2 translation table descriptor. See also [Hyp mode control of Non-secure access permissions on page G4-4075](#).

In addition, System register controls can enforce execute-never restrictions, regardless of the settings in the translation table XN and PXN fields, see:

- [Restriction on Secure instruction fetch on page G4-4073](#).
- [Preventing execution from writable locations on page G4-4073](#).

The execute-never controls apply also to speculative instruction fetching. This means a speculative instruction fetch from a memory region that is execute-never at the current level of privilege is prohibited.

The XN control means that, when the stage of address translation is enabled, the PE can fetch, or speculatively fetch, an instruction from a memory location only if all of the following apply:

- If using the Short-descriptor translation table format, the translation table descriptor for the location does not indicate that it is in a No access domain.
- If using the Long-descriptor translation table format, or using the Short descriptor format and the descriptor indicates that the location is in a Client domain, in the descriptor for the location the following apply:
 - XN is set to 0.
 - The access permissions permit a read access from the current PE mode.

- No other Prefetch Abort condition exists.

Note

- The PXN control applies to the PE privilege when it attempts to execute the instruction. In an implementation that fetches instructions speculatively, this might not be the privilege when the instruction was prefetched. Therefore, the architecture does not require the PXN control to prevent instruction fetching.
- Although the XN control applies to speculative fetching, on a speculative instruction fetch from an XN location, no Permission fault is generated unless the PE attempts to execute the instruction that would have been fetched from that location. This means that, if a speculative fetch from an XN location is attempted, but there is no attempt to execute the corresponding instruction, a Permission fault is not generated.
- The software that defines a translation table must mark any region of memory that is read-sensitive as XN, to avoid the possibility of a speculative fetch accessing the memory region. This means it must mark any memory region that corresponds to a read-sensitive peripheral as XN. Hardware does not prevent speculative accesses to a region of any Device memory type unless that region is also marked as execute-never for all Exception levels from which it can be accessed.
- When using the Short-descriptor translation table format, the XN attribute is not checked for domains marked as Manager. Therefore, the system must not include read-sensitive memory in domains marked as Manager, because the XN bit does not prevent speculative fetches from a Manager domain.

When no stage of address translation for the translation regime is enabled, memory regions cannot have XN or PXN attributes assigned. [Behavior of instruction fetches when all associated address translations are disabled on page G4-4033](#) describes how disabling all MMUs affects instruction fetching.

Hierarchical control of instruction fetching, Long-descriptor format

The Long-descriptor translation table format introduces a mechanism that means entries at one level of translation tables lookup can set limits on the permitted entries at subsequent levels of lookup. This applies to the restrictions on instruction fetching, and also to the access permissions described in [Hierarchical control of access permissions, Long-descriptor format on page G4-4069](#).

The restrictions apply only to subsequent levels of lookup at the same stage of translation, and:

- XNTable restricts the XN control:
 - When XNTable is set to 1, the XN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
 - When XNTable is set to 0 it has no effect.
- PXNTable restricts the PXN control:
 - When PXNTable is set to 1, the PXN bit is treated as 1 in all subsequent levels of lookup, regardless of the actual value of the bit.
 - When PXNTable is set to 0 it has no effect.

Note

The XNTable and PXNTable settings are combined with the XN and PXN bits in the translation table descriptors accessed at subsequent levels of lookup. They do not restrict or change the values entered in those descriptors.

The XNTable and PXNTable controls are provided only in the Long-descriptor translation table format, and only for stage 1 translations. The corresponding bits are SBZ in the stage 2 translation table descriptors.

The effect of XNTable or PXNTable applies to later entries in the translation table walk, and so its effects can be held in one or more TLB entries. Therefore, a change to XNTable or PXNTable requires coarse-grained invalidation of the TLB to ensure that the effect of the change is visible to subsequent memory transactions.

Preventing execution from writable locations

ARMv8 provides control bits that, when the corresponding stage 1 address translation is enabled, force writable memory to be treated as **XN** or **PXN**, regardless of the value of the **XN** or **PXN** bit. When the translation stages are controlled by an Exception level that is using AArch32:

- For PL1&0 stage 1 translations, when **SCTLR.WXN** is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.
- For PL1&0 stage 1 translations, when **SCTLR.UWXN** is set to 1, an instruction fetch is treated as accessing a PXN region if it accesses a region that software executing at PL0 can write to.
- For Non-secure PL2 stage 1 translations, when **HSCTLR.WXN** is set to 1, all regions that are writable at stage 1 of the address translation are treated as XN.

Note

- The **SCTLR.WXN** controls are intended to be used in systems with very high security requirements.
- Setting a **WXN** or **UWXN** bit to 1 changes the interpretation of the translation table entry, overriding a zero value of an **XN** or **PXN** field. It does not cause any change to the translation table entry.

For any given virtual machine, ARM expects **WXN** and **UWXN** to remain static in normal operation. In particular, it is IMPLEMENTATION DEFINED whether TLB entries associated with a particular VMID reflect the effect of the values of these fields. A generic sequence to ensure synchronization of a change to these fields, when that change is made without a corresponding change of VMID, is:

```
Change the WXN or UWXN bit
ISB                               ; This ensures synchronization of the change
Invalidate entire TLB of associated entries
DSB                               ; This completes the TLB Invalidation
ISB                               ; This ensures instruction synchronization
```

As with all Permission fault checking, if the stage 1 translation is using the Short-descriptor translation table format, the permission checks are performed only for Client domains. For more information see [Access permissions on page G4-4068](#).

For more information about address translation see [About address translation for VMSAv8-32 on page G4-4026](#).

Restriction on Secure instruction fetch

EL3 provides a Secure instruction fetch bit, **SCR.SIF**. When this bit is set to 1, any attempt in Secure state to execute an instruction fetched from Non-secure physical memory causes a Permission fault. As with all Permission fault checking, when using the Short-descriptor format translation tables the check applies only to Client domains, see [Access permissions on page G4-4068](#).

ARM expects **SCR.SIF** to be static during normal operation. In particular, whether the TLB holds the effect of the **SIF** bit is IMPLEMENTATION DEFINED. The generic sequence to ensure visibility of a change to the **SIF** bit is:

```
Change the SCR.SIF bit
ISB                               ; This ensures synchronization of the change
Invalidate entire TLB
DSB                               ; This completes the TLB Invalidation
ISB                               ; This ensures instruction synchronization
```

G4.6.3 Domains, Short-descriptor format only

A domain is a collection of memory regions. The Short-descriptor translation table format supports 16 domains, and requires the software that defines a translation table to assign each VMSAv8-32 memory region to a domain. When using the Short-descriptor format:

- Level 1 translation table entries for Page tables and Sections include a domain field.

- Translation table entries for Supersections do not include a domain field. The Short-descriptor format defines Supersections as being in domain 0.
- Level 2 translation table entries inherit a domain setting from the parent level 1 Page table descriptor.
- Each TLB entry includes a domain field.

The domain field specifies which of the 16 domains the entry is in, and a two-bit field in the [DACR](#) defines the permitted access for each domain. The possible settings for each domain are:

No access Any access using the translation table descriptor generates a Domain fault.

Clients On an access using the translation table descriptor, the access permission attributes are checked. Therefore, the access might generate a Permission fault.

Managers On an access using the translation table descriptor, the access permission attributes are not checked. Therefore, the access cannot generate a Permission fault.

See [The MMU fault-checking sequence on page G4-4113](#) for more information about how, when using the Short-descriptor translation table format, the Domain attribute affects the checking of the other attributes in the translation table descriptor.

———— **Note** —————

A single program might:

- Be a Client of some domains.
- Be a Manager of some other domains.
- Have no access to the remaining domains.

The Long-descriptor translation table format does not support domains. When a stage of translation is using this format, all memory is treated as being in a Client domain, and the settings in the [DACR](#) are ignored.

G4.6.4 The Access flag

The Access flag indicates when a page or section of memory is accessed for the first time since the Access flag in the corresponding translation table descriptor was set to 0:

- If address translation is using the Short-descriptor translation table format, it must set [SCTLR.AFE](#) to 1 to enable use of the Access flag. Setting this bit to 1 redefines the AP[0] bit in the translation table descriptors as an Access flag, and limits the access permissions information in the translation table descriptors to AP[2:1], as described in [AP\[2:1\] access permissions model on page G4-4069](#).
- The Long-descriptor format always supports an Access flag bit in the translation table descriptors, and address translation using this format behaves as if [SCTLR.AFE](#) is set to 1, regardless of the value of that bit.

In ARMv8.0, the Access flag is managed by software as described in [Software management of the Access flag](#).

———— **Note** —————

Previous version of the ARM architecture optionally supported hardware management of the Access flag. ARMv8.0 obsoletes this option.

Software management of the Access flag

ARMv8.0 requires that software manages the Access flag. This means an Access flag fault is generated whenever an attempt is made to read into the TLB a translation table descriptor entry for which the value of the Access flag is 0.

Note

When using the Short-descriptor translation table format, Access flag faults are generated only if `SCTLR.AFE` is set to 1, to enable use of a translation table descriptor bit as an Access flag.

The Access flag mechanism expects that, when an Access flag fault occurs, software resets the Access flag to 1 in the translation table entry that caused the fault. This prevents the fault occurring the next time that memory location is accessed. Entries with the Access flag set to 0 are never held in the TLB, meaning software does not have to flush the entry from the TLB after setting the flag.

Note

If a system incorporates components that can autonomously update translation table entries that are shared with the ARM PE, then the software must be aware of the possibility that such components can update the access flag autonomously.

In such a system, system software should perform any changes of translation table entries with an Access flag of 0, other than changes to the Access flag value, by using an Load-Exclusive/Store-Exclusive loop, to allow for the possibility of simultaneous updates.

G4.6.5 Hyp mode control of Non-secure access permissions

When EL2 is using AArch32, Non-secure software executing in Hyp mode controls two sets of translation tables, both of which use the Long-descriptor translation table format:

- The translation tables that control the Non-secure PL2 stage 1 translations. These map VAs to PAs, for memory accesses made when executing in Non-secure state in Hyp mode, and are indicated and controlled by the `HTTBR` and `HTCR`.

These translations have similar access controls to other Non-secure stage 1 translations using the Long-descriptor translation table format, as described in:

- [AP\[2:1\] access permissions model on page G4-4069](#).
- [Execute-never restrictions on instruction fetching on page G4-4071](#).

The differences from the Non-secure stage 1 translations are that:

- The `APTable[0]`, `PXNTable`, and `PXN` bits are reserved, `SBZ`.
- `AP[1]` is reserved, `SBO`.

- The translation tables that control the Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, for memory accesses made when executing in Non-secure state at PL1 or PL0, and are indicated and controlled by the `VTTBR` and `VTCR`.

The descriptors in the virtualization translation tables define stage 2 access permissions, that are combined with the permissions defined in the stage 1 translation. This section describes this combining of access permissions.

Note

The level 2 access permissions mean a hypervisor can define additional access restrictions to those defined by a Guest OS in the stage 1 translation tables. For a particular access, the actual access permission is the more restrictive of the permissions defined by:

- The Guest OS, in the stage 1 translation tables.
- The hypervisor, in the stage 2 translation tables.

The stage 2 access controls defined from Hyp mode:

- Affect only the Non-secure stage 1 access permissions settings.
- Take no account of whether the accesses are from a Non-secure PL1 mode or a Non-secure PL0 mode.
- Permit software executing in Hyp mode to assign a write-only attribute to a memory region.

The S2AP field in the stage 2 descriptors define the stage 2 access permissions, as [Table G4-10](#) shows:

Table G4-10 Stage 2 control of access permissions

| S2AP | Access permission |
|------|---|
| 00 | No access permitted |
| 01 | Read-only. Writes to the region are not permitted, regardless of the stage 1 permissions. |
| 10 | Write-only. Reads from the region are not permitted, regardless of the stage 1 permissions. |
| 11 | Read/write. The stage 1 permissions determine the access permissions for the region. |

For more information about the S2AP field see [Attribute fields in VMSEA8-32 Long-descriptor stage 2 Block and Page descriptors on page G4-4055](#).

If the stage 2 permissions cause a Permission fault, this is a stage 2 MMU fault. Stage 2 MMU faults are taken to Hyp mode, and reported in the [HSR](#) using an EC code of 0x20 or 0x24. For more information, see [Use of the HSR on page G4-4137](#).

———— **Note** ————

In the [HSR](#), the combination of the EC code and the DFSC or IFSC value in the ISS indicate that the fault is a stage 2 MMU fault.

The stage 2 permissions include an XN attribute. If this is set to 1, execution from the region is not permitted, regardless of the value of the XN attribute in the stage 1 translation. If a Permission fault is generated because the stage 2 XN bit is set to 1, this is reported as a stage 2 MMU fault.

[AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#) describes the abort prioritization if both stages of a translation generate a fault.

G4.7 Memory region attributes

In addition to an output address, a translation table entry that refers to a page or region of memory includes fields that define properties of that target memory region. [Information returned by a translation table lookup on page G4-4036](#) describes the classification of those fields as address map control, access control, and memory attribute fields. The memory region attribute fields control the memory type, Cacheability, and Shareability of the region.

The following sections describe the assignment of memory region attributes for stage 1 translations:

- [Overview of memory region attributes for stage 1 translations.](#)
- [Short-descriptor format memory region attributes, without TEX remap on page G4-4078.](#)
- [Short-descriptor format memory region attributes, with TEX remap on page G4-4080.](#)
- [VMSAv8-32 Long-descriptor format memory region attributes on page G4-4083.](#)

For an implementation that is operating in Secure state, or in Hyp mode, these assignments define the memory attributes of the accessed region.

For an implementation that is operating in a Non-secure PL1 or PL0 mode, the Non-secure PL1&0 stage 2 translation can modify the memory attributes assigned by the stage 1 translation. [EL2 control of Non-secure memory region attributes on page G4-4085](#) describes these stage 2 assignments.

G4.7.1 Overview of memory region attributes for stage 1 translations

The description of the memory region attributes in a translation descriptor divides into:

Memory type and attributes

These are described either:

- Directly, by bits in the translation table descriptor.
- Indirectly, by registers referenced by bits in the table descriptor. This is described as *remapping* the memory type and attribute description.

The Short-descriptor translation table format can use either of these approaches, selected by the `SCTLR.TRE` bit:

TRE == 0 Remap disabled. The `TEX[2:0]`, `C`, and `B` bits in the translation table descriptor define the memory region attributes. [Short-descriptor format memory region attributes, without TEX remap on page G4-4078](#) describes this encoding.

———— Note ————

With the Short-descriptor format, remapping is called *TEX remap*, and the `SCTLR.TRE` bit is the *TEX remap enabled* bit.

The description of the `TRE == 0` encoding includes information about the encoding in previous versions of the architecture.

TRE == 1 Remap enabled. The `TEX[0]`, `C`, and `B` bits in the translation table descriptor are index bits to the remap registers, that define the memory region attributes:

- The Primary Region Remap Register, `PRRR`.
- The Normal Memory Remap Register, `NMRR`.

[Short-descriptor format memory region attributes, with TEX remap on page G4-4080](#) describes this encoding scheme.

This scheme reassigns translation table descriptor bits `TEX[2:1]` for use as bits managed by the operating system.

The Long-descriptor translation table format always uses remapping. This means that when the value of `TTBCR.EAE` is 1, enabling use of the Long-descriptor translation table format, `SCTLR.TRE` is `RES1`.

[VMSAv8-32 Long-descriptor format memory region attributes on page G4-4083](#) describes this encoding.

Shareability In the Short-descriptor translation table format, the S bit in the translation table descriptor is used in determining the Shareability of the region. How the S bit is interpreted depends on whether TEX remap is enabled, see:

- [Shareability and the S bit, without TEX remap on page G4-4079.](#)
- [Determining the Shareability, with TEX remap on page G4-4081.](#)

In the Long-descriptor translation table format, the SH[1:0] field in the translation table descriptor encodes the Shareability of the region, see [Shareability, Long-descriptor format on page G4-4083.](#)

———— **Note** —————

Shareability is one of Non-shareable, Inner Shareable, and Outer Shareable. However, when using the Short-descriptor translation table format without TEX remap, VMSAv8-32 does not support any distinction between Inner Shareable and Outer Shareable memory, and a memory region is either Non-shareable or Outer Shareable.

G4.7.2 Short-descriptor format memory region attributes, without TEX remap

When using the Short-descriptor translation table formats, TEX remap is disabled when the value of `SCTLR.TRE` is 0.

———— **Note** —————

- The Short-descriptor format scheme without TEX remap is the scheme used in VMSAv6.
- The B (Bufferable), C (Cacheable), and TEX (Type extension) bit names are inherited from earlier versions of the architecture. These names no longer adequately describe the function of the B, C, and TEX bits.

[Table G4-11](#) shows the C, B, and TEX[2:0] encodings when TEX remap is disabled. In the [Page Shareability](#) column, an entry of *S bit* indicates that the S bit in the translation table descriptor determines the Shareability, see [Shareability and the S bit, without TEX remap on page G4-4079.](#)

Table G4-11 TEX, C, and B encodings when TRE == 0

| TEX[2:0] | C | B | Description | Memory type | Page Shareability |
|----------|---|---|---|------------------------|------------------------------|
| 000 | 0 | 0 | Device-nGnRnE | Device-nGnRnE | Outer Shareable |
| | | 1 | Device-nGnRE ^a | Device-nGnRE | Outer Shareable ^a |
| | 1 | 0 | Outer and Inner Write-Through, Read-Allocate No Write-Allocate | Normal | S bit |
| | | 1 | Outer and Inner Write-Back, Read-Allocate No Write-Allocate | Normal | S bit |
| 001 | 0 | 0 | Outer and Inner Non-cacheable | Normal | Outer Shareable ^b |
| | | 1 | Reserved | - | - |
| | 1 | 0 | IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED | IMPLEMENTATION DEFINED |
| | | 1 | Outer and Inner Write-Back, Read-Allocate Write-Allocate | Normal | S bit |
| 010 | 0 | 0 | Device-nGnRE ^a | Device-nGnRE | Outer Shareable ^a |
| | | 1 | Reserved | - | - |
| | 1 | x | Reserved | - | - |

Table G4-11 TEX, C, and B encodings when TRE == 0 (continued)

| TEX[2:0] | C | B | Description | Memory type | Page Shareability |
|----------|---|---|--|-------------|-------------------|
| 011 | x | x | Reserved | - | - |
| 1BB | A | A | Cacheable memory: AA = Inner attribute ^c BB = Outer attribute | Normal | S bit |

- In ARMv8, all Device memory types are Outer Shareable. For the Device-nGnRE memory type this is a change from previous versions of the architecture. This is why Device-nGnRE memory has two entries in this table. For compatibility with ARMv7 software should use the {TEX, C, B} values {000, 0, 1}.
- In ARMv8, Normal Inner Non-cacheable, Outer Non-cacheable memory is always Outer Shareable. This is a change from previous versions of the architecture, where the S bit determined the Shareability. For compatibility with ARMv7 software should set S to 1.
- For more information, see [Cacheability attributes, without TEX remap](#).

See [Memory types and attributes on page E2-2342](#) for an explanation of Normal memory, and the types of Device memory, and of the Shareability attribute.

Cacheability attributes, without TEX remap

When the value of TEX[2] is 0, the same Cacheability attribute applies to Inner Cacheable and Outer Cacheable memory regions, and the {TEX[1:0], C, B} values identify this attribute, as [Table G4-11 on page G4-4078](#) shows.

When the value of TEX[2] is 1, the memory described by the translation table entry is cacheable, and the rest of the encoding defines the Inner Cacheability and Outer Cacheability attributes:

- TEX[1:0]** Define the Outer Cacheability attribute.
C, B Define the Inner Cacheability attribute.

The translation table entries use the same encoding for the Outer and Inner Cacheability attributes, as [Table G4-12](#) shows.

Table G4-12 Inner and Outer Cacheability attribute encoding

| Encoding | Cacheability attribute |
|----------|--|
| 00 | Non-cacheable |
| 01 | Write-Back, Read-Allocate Write-Allocate |
| 10 | Write-Through, Read Allocate No Write-Allocate |
| 11 | Write-Back, Read Allocate No Write-Allocate |

Shareability and the S bit, without TEX remap

The Short-descriptor format translation table entries include an S bit. This bit:

- Is ignored if the entry refers to any type of Device memory, or to Normal memory that is Inner Non-cacheable, Outer Non-cacheable.
- For Normal memory that is not Inner Non-cacheable, Outer Non-cacheable, determines whether the memory region is Outer Shareable or Non-shareable:
 - S == 0** Normal memory region is Non-shareable.
 - S == 1** Normal memory region is Outer Shareable.

Without TEX remapping there is no distinction between Inner Shareable and Outer Shareable memory, meaning the S bit determines whether the region is Non-shareable or Outer Shareable.

G4.7.3 Short-descriptor format memory region attributes, with TEX remap

When using the Short-descriptor translation table formats, TEX remap is enabled when the value of `SCTLR.TRE` is 1. In this configuration:

- The software that defines the translation tables must program the `PRRR` and `NMRR` to define seven possible memory region attributes.
- The `TEX[0]`, `C`, and `B` bits of the translation table descriptors define the memory region attributes, by indexing `PRRR` and `NMRR`.
- Hardware makes no use of `TEX[2:1]`, see *The OS managed translation table bits* on page G4-4082.

When TEX remap is enabled:

- For seven of the eight possible combinations of the `TEX[0]`, `C` and `B` bits, fields in the `PRRR` and `NMRR` define the region attributes, as described in this section.
- The meaning of the eighth combination for the `TEX[0]`, `C` and `B` bits is IMPLEMENTATION DEFINED.
- If the `TEX[0]`, `C` and `B` bits determine that the region is a Device memory type, or is Normal Inner Non-cacheable, Outer Non-cacheable, then the region is Outer Shareable. Otherwise, the Shareability is determined by the combination of:
 - The `S` bit from the translation table descriptor.
 - The value of the `PRRR.NS0` or `PRRR.NS1` bit.
 - The value of the appropriate `PRRR.NOSn` bit, as shown in Table G4-13.

For more information, see *Determining the Shareability, with TEX remap* on page G4-4081.

For each of the possible encodings of the `TEX[0]`, `C`, and `B` bits in a translation table entry, Table G4-13 shows which fields of the `PRRR` and `NMRR` registers describe the memory region attributes.

Table G4-13 TEX, C, and B encodings when TRE == 1

| Encoding TEX[0] | C | B | Memory type ^a | Cache attributes ^{a, b} : | | Outer Shareable attribute ^{a, c} |
|--------------------|---|---|--------------------------|------------------------------------|-----------------------|---|
| | | | | Inner cacheability | Outer cacheability | |
| 0 | 0 | 0 | <code>PRRR.TR0</code> | <code>NMRR.IR0</code> | <code>NMRR.OR0</code> | NOT(<code>PRRR.NOS0</code>) |
| | | 1 | <code>PRRR.TR1</code> | <code>NMRR.IR1</code> | <code>NMRR.OR1</code> | NOT(<code>PRRR.NOS1</code>) |
| | 1 | 0 | <code>PRRR.TR2</code> | <code>NMRR.IR2</code> | <code>NMRR.OR2</code> | NOT(<code>PRRR.NOS2</code>) |
| | | 1 | <code>PRRR.TR3</code> | <code>NMRR.IR3</code> | <code>NMRR.OR3</code> | NOT(<code>PRRR.NOS3</code>) |
| 1 | 0 | 0 | <code>PRRR.TR4</code> | <code>NMRR.IR4</code> | <code>NMRR.OR4</code> | NOT(<code>PRRR.NOS4</code>) |
| | | 1 | <code>PRRR.TR5</code> | <code>NMRR.IR5</code> | <code>NMRR.OR5</code> | NOT(<code>PRRR.NOS5</code>) |
| | 1 | 0 | IMPLEMENTATION DEFINED | | | |
| | | 1 | <code>PRRR.TR7</code> | <code>NMRR.IR7</code> | <code>NMRR.OR7</code> | NOT(<code>PRRR.NOS7</code>) |

a. For details of the *Memory type* and *Outer Shareable* encodings see the description of the `PRRR`. For details of the *Cache attributes* encodings the description of the `NMRR`.

b. Applies only if the memory type for the region is mapped as Normal memory.

c. Applies only if both of the following apply:

- The memory type for the region is mapped as Normal memory that is not Inner Non-cacheable and Outer Non-cacheable.
- The region is not Non-shareable.

See *Determining the Shareability, with TEX remap* on page G4-4081.

As [Table G4-13 on page G4-4080](#) shows, when TEX remap is enabled, for a given set of {TEX[0], C, B} bits from a translation table descriptor:

1. The primary mapping, to memory type, is given by the **PRRR.TR_n** field as shown in the [Memory type](#) column.
2. For any region that the **PRRR.TR_n** maps as Normal memory, **NMRR.IR_n** determines the Inner cacheability attribute, and **NMRR.OR_n** determines the Outer cacheability attribute.
3. For a region that **PRRR.TR_n** maps as Normal memory, if **NMRR.{IR_n, OR_n}** do not map the region as Inner Non-cacheable, Outer Non-cacheable, **PRRR.{NS0, NS1}** and **PRRR.NOS_n** are used to determine the Shareability of the region, see [Determining the Shareability, with TEX remap](#).

The TEX remap registers and the **SCTLR.TRE** bit are Banked between the Secure and Non-secure Security states. For more information, see [The effect of EL3 on TEX remap on page G4-4083](#).

The TEX remap registers must be static during normal operation. In particular, when the remap registers are changed:

- It is IMPLEMENTATION DEFINED when the changes take effect.
- It is CONSTRAINED UNPREDICTABLE whether the TLB caches the effect of the TEX remap on translation tables, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5461](#).

The software sequence to ensure the synchronization of changes to the TEX remap registers is:

1. Execute a DSB instruction. This ensures any memory accesses using the old mapping have completed.
2. Write the TEX remap registers or **SCTLR.TRE** bit.
3. Execute an ISB instruction. This ensures synchronization of the register updates.
4. Invalidate the entire TLB.
5. Execute a DSB instruction. This ensures completion of the entire TLB operation.
6. Clean and invalidate all caches. This removes any cached information associated with the old mapping.
7. Execute a DSB instruction. This ensures completion of the cache maintenance.
8. Execute an ISB instruction. This ensures instruction synchronization.

This extends the standard rules for the synchronization of changes to System registers described in [Synchronization of changes to AArch32 System registers on page G4-4163](#), and provides implementation freedom as to whether or not the effect of the TEX remap is cached.

Determining the Shareability, with TEX remap

The memory type of a region, as indicated in the [Memory type](#) column of [Table G4-13 on page G4-4080](#), provides the first level of control of the Shareability of the region:

- If the memory is any type of Device memory, then the region is Outer Shareable, and any Shareability attributes in the translation table descriptor and **PRRR** for that region are ignored.
This applies also to a Normal memory region that the **NMRR** attributes identify as Inner Non-cacheable and Outer Non-cacheable,
- If using the Short descriptor translation table format then the Shareability of the region is determined using the value of the S bit in the translation table descriptor to index one of the **PRRR.{NS1, NS0}** bits, as described in this section.

[Table G4-14](#) shows how the translation table S bit indexes into the **PRRR**:

Table G4-14 Determining the Shareability attribute, with TEX remap

| Memory type | Remapping when S == 0 | Remapping when S == 1 |
|---|-----------------------|-----------------------|
| Device or Normal Inner Non-cacheable, Outer Non-cacheable | Outer Shareable | Outer Shareable |
| Normal, not Inner Non-cacheable, Outer Non-cacheable | PRRR.NS0 | PRRR.NS1 |

For a Normal memory region that is not Inner Non-cacheable, Outer Non-cacheable, the appropriate bit of the **PRRR** indicates whether the region is Non-shareable, as follows:

PRRR.NSn==0 Non-shareable.

PRRR.{NOS7:NOS0} are ignored.

PRRR.NSn==1 The appropriate **PRRR.NOSm** field, as shown in [Table G4-13 on page G4-4080](#), indicates whether the region is Inner Shareable or Outer Shareable:

PRRR.NOSm==0 Region is Outer Shareable.

PRRR.NOSm==1 Region is Inner Shareable.

———— **Note** —————

This means that TEX remapping can map a translation table entry with $S == 0$ as shareable memory.

SCTLR.TRE, SCTLR.M, and the effect of the TEX remap registers

When TEX remap is disabled, because the value of the **SCTLR.TRE** bit is 0:

- The effect of the **PRRR** and **NMRR** registers can be IMPLEMENTATION DEFINED.
- The interpretation of the fields of the **PRRR** and **NMRR** registers can differ from the description given earlier in this section. One implication of this is that the implementation can provide an IMPLEMENTATION DEFINED mechanism to interpret the **PRRR**.{NOS7:NOS0} fields.

VMSAv8-32 requires that the effect of these registers is limited to remapping the attributes of memory locations. These registers must not change whether any cache hardware or stages of address translation are enabled. The mechanism by which the TEX remap registers have an effect when the value of the **SCTLR.TRE** bit is 0 is IMPLEMENTATION DEFINED. The AArch32 architecture requires that from reset, if the IMPLEMENTATION DEFINED mechanism has not been invoked:

- If the PL1&0 stage 1 address translation is enabled and is using the Short-descriptor format translation tables, the architecturally-defined behavior of the TEX[2:0], C, and B bits must apply, without reference to the TEX remap functionality. In other words, memory attribute assignment must comply with the scheme described in [Short-descriptor format memory region attributes, without TEX remap on page G4-4078](#).
- If the PL1&0 stage 1 address translation is disabled, then the architecturally-defined behavior of VMSAv8-32 with address translation disabled must apply, without reference to the TEX remap functionality. See [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4031](#).

Possible mechanisms for enabling the IMPLEMENTATION DEFINED effect of the TEX remap registers when the value of **SCTLR.TRE** is 0 include:

- A control bit in the **ACTLR**, or in an IMPLEMENTATION DEFINED System register.
- Changing the behavior when the **PRRR** and **NMRR** registers are changed from their IMPLEMENTATION DEFINED reset values.

In addition, if the stage of address translation is disabled and the value of the **SCTLR.TRE** bit is 1, the architecturally-defined behavior of the VMSAv8-32 with the stage of address translation disabled must apply without reference to the TEX remap functionality.

In an implementation that includes EL3, the IMPLEMENTATION DEFINED effect of these registers must only take effect in the Security state of the registers. See also [The effect of EL3 on TEX remap on page G4-4083](#).

The OS managed translation table bits

When TEX remap is enabled, the TEX[2:1] bits in the translation table descriptors are available as two bits that can be managed by the operating system. In VMSAv8-32, as long as the **SCTLR.TRE** bit is set to 1, the values of the TEX[2:1] bits are IGNORED by the PE. Software can write any value to these bits in the translation tables.

The effect of EL3 on TEX remap

In an implementation that includes EL3, when EL3 is using AArch32, the TEX remap registers are Banked between the Secure and Non-secure Security states. When EL3 is using AArch32, write accesses to the Secure register for the current security state apply to all PL1&0 stage 1 translation table lookups in that state. The `SCTLR.TRE` bit is Banked in the Secure and Non-secure copies of the register, and the appropriate version of this bit determines whether TEX remap is applied to translation table lookups in the current security state.

Write accesses to the Secure copies of the TEX remap registers are disabled when the `CP15SDISABLE` input is asserted HIGH, meaning the MCR operations to access these registers are UNDEFINED. For more information, see [The CP15SDISABLE input signal on page G4-4161](#).

G4.7.4 VMSAv8-32 Long-descriptor format memory region attributes

When a PE is using the VMSAv8-32 Long-descriptor translation table format, the `AttrIdx[2:0]` field in a block or page translation table descriptor for a stage 1 translation indicates the 8-bit field, in the appropriate MAIR register, that specifies the attributes for the corresponding memory region, as follows:

- `AttrIdx[2]` indicates the MAIR register to be used:
`AttrIdx[2] == 0` Use `MAIR0`.
`AttrIdx[2] == 1` Use `MAIR1`.
- `AttrIdx[2:0]` indicates the required Attr field, `Attr n` , where $n = \text{AttrIdx}[2:0]$.

Each `AttrIdx` field defines, for the corresponding memory region:

- The memory type, Normal or a type of Device memory.
- For Normal memory:
 - The Inner cacheability and Outer cacheability attributes, each of which is one of Non-cacheable, Write-Through Cacheable, or Write-Back Cacheable.
 - For Write-Through Cacheable and Write-Back Cacheable regions, the Read-Allocate and Write-Allocate policy hints, each of which is *Allocate* or *No allocate*.

For more information about the `AttrIdx[2:0]` descriptor field, see [Attribute fields in VMSAv8-32 Long-descriptor stage 1 Block and Page descriptors on page G4-4054](#).

Shareability, Long-descriptor format

When a PE is using the Long-descriptor translation table format, the `SH[1:0]` field in a block or page translation table descriptor specifies the Shareability attributes of the corresponding memory region, if the MAIR entry for that region identifies it as Normal memory that is not both Inner Non-cacheable and Outer Non-cacheable. [Table G4-15](#) shows the encoding of this field.

Table G4-15 SH[1:0] field encoding for Normal memory, Long-descriptor format

| SH[1:0] | Normal memory |
|---------|--|
| 00 | Non-shareable |
| 01 | Reserved, CONSTRAINED UNPREDICTABLE, see Reserved values in System and memory-mapped registers and translation table entries on page K1-5477 for the permitted behavior. |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

See [Combining the Shareability attribute on page G4-4088](#) for constraints on the Shareability attributes of a Normal memory region that is Inner Non-cacheable, Outer Non-cacheable.

For any type of Device memory, and for Normal Inner Non-cacheable, Outer Non-cacheable memory, the value of the SH[1:0] field of the translation table descriptor is ignored.

Other fields in the Long-descriptor translation table format descriptors

The following subsections describe the other fields in the translation table block and page descriptors when a PE is using the Long-descriptor translation table format:

- [Contiguous bit](#)
- [IGNORED fields](#).
- [Field reserved for software use](#)

Contiguous bit

The Long-descriptor translation table format descriptors contain a Contiguous bit. Setting this bit to 1 indicates that 16 adjacent translation table entries point to a *contiguous output address range*. These 16 entries must be aligned in the translation table so that the top five bits of their input addresses, that index their position in the translation table, are the same. For example, to use this bit for a block of 16 entries in the level 3 translation table, bits[20:16] of the input addresses for the 16 entries must be the same.

The contiguous output address range must be aligned to size of 16 translation table entries at the same translation table level.

Use of this bit means that the TLB can cache a single entry to cover the 16 translation table entries.

This bit acts as a hint. The architecture does not require a PE to cache TLB entries in this way. To avoid TLB coherency issues, any TLB maintenance by address must not assume any optimization of the TLB tables that might result from use of this bit.

———— Note —————

The use of the contiguous bit is similar to the approach used, in the Short-descriptor translation table format, for optimized caching of Large Pages and Supersections in the TLB. However, an important difference in the contiguous bit capability is that TLB maintenance must be performed based on the size of the underlying translation table entries, to avoid TLB coherency issues. That is, any use of the contiguous bit has no effect on the minimum size of entry that must be invalidated from the TLB.

IGNORED fields

For stage 1 and stage 2 Block and Page descriptors, the architecture defines bits[63:59] and bits[58:55] as IGNORED fields, meaning the architecture guarantees that a PE makes no use of these fields. In addition:

- Bits[58:55] are reserved for software use, see [Field reserved for software use](#).
- In the stage 2 Block and Page descriptors, bits[63:60] are reserved for use by a System MMU.

———— Note —————

The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.

Field reserved for software use

The architecture reserves a 4-bit field in the Block and Page table descriptors, bits[58:55], for software use. In considering migration from using the Short-descriptor format to the Long-descriptor format, this field is an extension of the Short-descriptor field described in [The OS managed translation table bits on page G4-4082](#).

———— Note —————

The definition of IGNORED means there is no need to invalidate the TLB if these bits are changed.

G4.7.5 EL2 control of Non-secure memory region attributes

Software executing at EL2 controls two sets of translation tables, both of which use the Long-descriptor translation table format. These are:

- The translation tables that control Non-secure PL2 stage 1 translations. These map VAs to PAs, and when EL2 is using AArch32 they are indicated and controlled by the [HTTBR](#) and [HTCR](#).
These translations have exactly the same memory region attribute controls as any other stage 1 translations, as described in [VMSAv8-32 Long-descriptor format memory region attributes on page G4-4083](#).
- The translation tables that control Non-secure PL1&0 stage 2 translations. These map the IPAs from the stage 1 translation onto PAs, and are indicated and when EL2 is using AArch32 they are controlled by the [VTTBR](#) and [VTCR](#).
The descriptors in the virtualization translation tables define level 2 memory region attributes, that are combined with the attributes defined in the stage 1 translation. This section describes this combining of attributes.

[VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4050](#) describes the format of the entries in these tables.

———— **Note** —————

In a virtualization implementation, a hypervisor might usefully:

- Reduce the permitted Cacheability of a region.
- Increase the required Shareability of a region.

The combining of attributes from stage 1 and stage 2 translations supports both of these options.

In the stage 2 translation table descriptors for memory regions and pages, the MemAttr[3:0] and SH[1:0] fields describe the stage 2 memory region attributes:

- The definition of the stage 2 SH[1:0] field is identical to the same field for a stage 1 translation, see [Shareability, Long-descriptor format on page G4-4083](#).
- MemAttr[3:2] give a top-level definition of the memory type, and of the cacheability of a Normal memory region, as [Table G4-16](#) shows:

Table G4-16 Long-descriptor MemAttr[3:2] encoding, stage 2 translation

| MemAttr[3:2] | Memory type | Cacheability |
|--------------|---|-------------------------------|
| 00 | Device, of type determined by MemAttr[1:0] | Not applicable |
| 01 | Normal, Inner cacheability determined by MemAttr[1:0] | Outer Non-cacheable |
| 10 | | Outer Write-Through Cacheable |
| 11 | | Outer Write-Back Cacheable |

The encoding of MemAttr[1:0] depends on the Memory type indicated by MemAttr[3:2]:

- When MemAttr[3:2]==0b00, indicating a type of Device memory, [Table G4-17](#) shows the encoding of MemAttr[1:0]:

Table G4-17 MemAttr[1:0] encoding for the types of Device memory

| MemAttr[1:0] | Meaning when MemAttr[3:2] == 0b00 |
|--------------|-----------------------------------|
| 00 | Region is Device-nGnRnE memory |
| 01 | Region is Device-nGnRE memory |
| 10 | Region is Device-nGRE memory |
| 11 | Region is Device-GRE memory |

- When MemAttr[3:2]!=0b00, indicating Normal memory, [Table G4-18](#) shows the encoding of MemAttr[1:0]:

Table G4-18 MemAttr[1:0] encoding for Normal memory

| MemAttr[1:0] | Meaning when MemAttr[3:2] != 0b00 |
|--------------|--|
| 00 | Reserved, CONSTRAINED UNPREDICTABLE, See Reserved values in System and memory-mapped registers and translation table entries on page K1-5477 for the permitted behavior. |
| 01 | Inner Non-cacheable |
| 10 | Inner Write-Through Cacheable |
| 11 | Inner Write-Back Cacheable |

Note

The stage 2 translation does not assign any allocation hints.

The following sections describe how the memory type attributes assigned at stage 2 of the translation are combined with those assigned at stage 1:

- [Combining the memory type attribute on page G4-4087.](#)
- [Combining the Cacheability attribute on page G4-4087.](#)
- [Combining the Shareability attribute on page G4-4088.](#)

Note

- The following stage 2 translation table attribute settings leave the stage 1 settings unchanged:
 - MemAttr[3:2] == 0b11, Normal memory, Outer Write-Back Cacheable.
 - MemAttr[1:0] == 0b11, Inner Write-Back Cacheable.
- In addition to the attribute combinations described in this section, [Execute-never restrictions on instruction fetching on page G4-4071](#) describes how the stage 1 and stage 1 XN permission fields are combined, so that a region is execute-never if the value of the XN field is 1 in at least one stage of translation.

Combining the memory type attribute

Table G4-19 shows how the stage 1 and stage 2 memory type assignments are combined:

Table G4-19 Combining the stage 1 and stage 2 memory type assignments

| Assignment in stage 1 | Assignment in stage 2 | Resultant type |
|-----------------------|-------------------------------------|---------------------------------|
| Device-nGnRnE | Any | Device-nGnRnE |
| Device-nGnRE | Device-nGnRnE | Device-nGnRnE |
| | Not Device-nGnRnE | Device-nGnRE |
| Device-nGRE | Device-nGnRnE | Device-nGnRnE |
| | Device-nGnRE | Device-nGnRE |
| | Not (Device-nGnRnE or Device-nGnRE) | Device-nGRE |
| Device-GRE | Device-nGnRnE | Device-nGnRnE |
| | Device-nGnRE | Device-nGnRE |
| | Device-nGRE | Device-nGRE |
| | Device-GRE or Normal | Device-GRE |
| Normal | Any type of Device | Device type assigned at stage 2 |
| | Normal | Normal |

See [Combining the Shareability attribute on page G4-4088](#) for information about the Shareability of:

- A region for which the resultant type is any Device type.
- A region with a resultant type of Normal for which the resultant cacheability, described in [Combining the Cacheability attribute](#), is Inner Non-cacheable, Outer Non-cacheable.

The combining of the memory type attribute means a translation table walk for a stage 1 translation can be made to a type of Device memory. If this occurs, then:

- If the value of [HCR.PTW](#) is 0, then the translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be done speculatively.
- If the value of [HCR.PTW](#) is 1, then the memory access generates a stage 2 Permission fault.

Combining the Cacheability attribute

For a Normal memory region, [Table G4-20](#) shows how the stage 1 and stage 2 Cacheability assignments are combined. This combination applies, independently, for the Inner Cacheability and Outer Cacheability attributes:

Table G4-20 Combining the stage 1 and stage 2 cacheability assignments

| Assignment in stage 1 | Assignment in stage 2 | Resultant cacheability |
|-----------------------|-----------------------|------------------------|
| Non-cacheable | Any | Non-cacheable |
| Any | Non-cacheable | Non-cacheable |

Table G4-20 Combining the stage 1 and stage 2 cacheability assignments (continued)

| Assignment in stage 1 | Assignment in stage 2 | Resultant cacheability |
|---------------------------------------|---------------------------------------|-------------------------|
| Write-Through Cacheable | Write-Through or Write-Back Cacheable | Write-Through Cacheable |
| Write-Through or Write-Back Cacheable | Write-Through Cacheable | Write-Through Cacheable |
| Write-Back Cacheable | Write-Back Cacheable | Write-Back Cacheable |

———— **Note** —————

Only Normal memory has a Cacheability attribute.

Combining the Shareability attribute

In the following cases, a memory region is treated as Outer Shareable, regardless of any shareability assignments at either stage of translation:

- The resultant memory type attribute, described in *Combining the memory type attribute on page G4-4087*, is any type of Device memory.
- The resultant memory type attribute is Normal memory, and the resultant Cacheability, described in *Combining the Cacheability attribute on page G4-4087*, is Inner Non-cacheable Outer Non-cacheable.

For a memory region with a resultant memory type attribute of Normal that is not Inner Non-cacheable Outer Non-cacheable, [Table G4-21](#) shows how the stage 1 and stage 2 shareability assignments are combined:

Table G4-21 Combining the stage 1 and stage 2 Shareability assignments

| Assignment in stage 1 | Assignment in stage 2 | Resultant Shareability |
|-----------------------|-----------------------|------------------------|
| Outer Shareable | Any | Outer Shareable |
| Inner Shareable | Outer Shareable | Outer Shareable |
| Inner Shareable | Inner Shareable | Inner Shareable |
| Inner Shareable | Non-shareable | Inner Shareable |
| Non-shareable | Outer Shareable | Outer Shareable |
| Non-shareable | Inner Shareable | Inner Shareable |
| Non-shareable | Non-shareable | Non-shareable |

G4.8 Translation Lookaside Buffers (TLBs)

Translation Lookaside Buffers (TLBs) are an implementation technique that caches translations or translation table entries. TLBs avoid the requirement to perform a translation table walk in memory for every memory access. The ARM architecture does not specify the exact form of the TLB structures for any design. In a similar way to the requirements for caches, the architecture only defines certain principles for TLBs:

- The architecture has a concept of an entry locked down in the TLB. The method by which lockdown is achieved is IMPLEMENTATION DEFINED, and an implementation might not support lockdown.
- The architecture does not guarantee that an unlocked TLB entry remains in the TLB.
- The architecture guarantees that a locked TLB entry remains in the TLB. However, a locked TLB entry might be updated by subsequent updates to the translation tables. Therefore, when a change is made to the translation tables, the architecture does not guarantee that a locked TLB entry remains incoherent with an entry in the translation table.
- The architecture guarantees that a translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault is not held in the TLB. However a translation table entry that generates a Domain fault or a Permission fault might be held in the TLB.
- When address translation is enabled, any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault and is not from a translation regime for an Exception level that is lower than the current Exception level can be allocated to a TLB at any time. The only translation table entries guaranteed not to be held in the TLB are those that generate a Translation fault, an Address size fault, or an Access flag fault.

———— **Note** —————

An TLB can hold translation table entries that do not generate a Translation fault but point to subsequent tables in the translation table walk. This can be referred to as *intermediate caching* of TLB entries.

- Software can rely on the fact that between disabling and re-enabling a stage of address translation, entries in the TLB relating to that stage of translation have not been corrupted to give incorrect translations.

The following sections give more information about TLB implementation:

- [Global and process-specific translation table entries](#).
- [TLB matching on page G4-4090](#).
- [TLB behavior at reset on page G4-4090](#).
- [TLB lockdown on page G4-4091](#).
- [TLB conflict aborts on page G4-4091](#).

See also [TLB maintenance requirements on page G4-4093](#).

G4.8.1 Global and process-specific translation table entries

For VMSAv8-32, system software can divide a virtual memory map used by memory accesses at PL1 and PL0 into global and non-global regions, indicated by the nG bit in the translation table descriptors:

- nG == 0** The translation is global, meaning the region is available for all processes.
- nG == 1** The translation is non-global, or process-specific, meaning it relates to the current ASID, as defined by:
- [TTBR0.ASID](#) or [TTBR1.ASID](#), if using the Long-descriptor translation table format. In this case, [TTBCR.A1](#) selects which ASID is current.
 - [CONTEXTIDR.ASID](#), if using the Short-descriptor translation table format.

Each non-global region has an associated ASID. These identifiers mean different translation table mappings can co-exist in a caching structure such as a TLB. This means that software can create a new mapping of a non-global memory region without removing previous mappings.

For a symmetric multiprocessor cluster where a single operating system is running on the set of PEs, the architecture requires all ASID values to be assigned uniquely within any single Inner Shareable domain. In other words, each ASID value must have the same meaning to all PEs in the system.

The translation regime used for accesses made at PL2 does not support ASIDs, and all pages are treated as global.

When a PE is using the Long-descriptor translation table format, and is in Secure state, a translation must be treated as non-global, regardless of the value of the nG bit, if NSTable is set to 1 at any level of the translation table walk.

For more information see *Control of Secure or Non-secure memory access, VMSAv8-32 Long-descriptor format on page G4-4056*.

G4.8.2 TLB matching

A TLB is a hardware caching structure for translation table information. Like other hardware caching structures, it is mostly invisible to software. However, there are some situations where it can become visible. These are associated with coherency problems caused by an update to the translation table that has not been reflected in the TLB. Use of the TLB maintenance instructions described in *TLB maintenance requirements on page G4-4093* can prevent any TLB incoherency becoming a problem.

A particular case where the presence of the TLB can become visible is if the translation table entries that are in use under a particular ASID and VMID are changed without suitable invalidation of the TLB. This can occur only if the architecturally-required break-before-make sequence described in *Using break-before-make when updating translation table entries on page G4-4094* is not used. If the break-before make sequence is not used, the TLB can hold two mappings for the same address, and this:

- Might generate an exception that is reported using the TLB Conflict fault code, see *TLB conflict aborts on page G4-4091*.
- Might lead to CONSTRAINED UNPREDICTABLE behavior. In this case, behavior will be consistent with one of the mappings held in the TLB, or with some amalgamation of the values held in the TLB, but cannot give access to regions of memory with permissions or attributes that could not be assigned by valid translation table entries in the translation regime being used for the access. See *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5461*.

G4.8.3 TLB behavior at reset

The ARM architecture does not require a reset to invalidate the TLBs, and recognizes that an implementation might require caches, including TLBs, to maintain context over a system reset. Possible reasons for doing so include power management and debug requirements.

Therefore, for ARMv8:

- All TLBs reset to an IMPLEMENTATION DEFINED state that might be UNKNOWN.
- All TLBs are disabled from reset. All stages of address translation that are used from the PE state entered on coming out of reset are disabled from reset, and the contents of the TLBs have no effect on address translation. For more information see *Enabling stages of address translation on page G4-4033*.
- An implementation can require the use of a specific TLB invalidation routine, to invalidate the TLB arrays before they are enabled after a reset. The exact form of this routine is IMPLEMENTATION DEFINED, but if an invalidation routine is required it must be documented clearly as part of the documentation of the device.

ARM recommends that if an invalidation routine is required for this purpose, and the PE resets into AArch32 state, the routine is based on the AArch32 TLB maintenance instructions described in *The scope of TLB maintenance instructions on page G4-4101*.

Similar rules apply:

- To cache behavior, see *Behavior of caches at reset on page G3-3995*.
- To branch predictor behavior, see *Behavior of the branch predictors at reset on page G3-4003*.

G4.8.4 TLB lockdown

The ARM architecture recognizes that any TLB lockdown scheme is heavily dependent on the microarchitecture, making it inappropriate to define a common mechanism across all implementations. This means that:

- The architecture does not require TLB lockdown support.
- If TLB lockdown support is implemented, the lockdown mechanism is IMPLEMENTATION DEFINED. However, key properties of the interaction of lockdown with the architecture must be documented as part of the implementation documentation.

This means that:

- The TLB Type Register, [TLBTR](#), does not define the lockdown scheme in use.
- In AArch32 state, a region of the {coproc==0b1111, CRn==c10} encodings is reserved for IMPLEMENTATION DEFINED TLB functions, such as TLB lockdown functions. The reserved encodings are those with:
 - <CRm> == {c0, c1, c4, c8}.
 - All values of <opc2> and <opc1>.

An implementation might use some of the {coproc==0b1111, CRn==c10} encodings that are reserved for IMPLEMENTATION DEFINED TLB functions to implement additional TLB control functions. These functions might include:

- Unlock all locked TLB entries.
- Preload into a specific level of TLB. This is beyond the scope of the PLI and PLD hint instructions.

The inclusion of EL2 in an implementation does not affect the TLB lockdown requirements. However, in an implementation that includes EL2, exceptions generated as a result of TLB lockdown when executing in a Non-secure PL1 mode or in Non-secure User mode can be routed to either:

- Non-secure Abort mode, using the Non-secure Data Abort exception vector.
- Hyp mode, using the Hyp Trap exception vector.

For more information, see [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-3900](#).

G4.8.5 TLB conflict aborts

If an address matches multiple entries in the TLB, it is IMPLEMENTATION DEFINED whether a TLB conflict abort is generated.

An implementation can generate TLB conflict aborts on either or both instruction fetches and data accesses. A TLB conflict abort is classified as an MMU fault, see [MMU faults in AArch32 state on page G4-4118](#). This means:

- A TLB conflict abort on an instruction fetch is reported as a Prefetch Abort exception,
- A TLB conflict abort on a data access is reported as a Data Abort exception,

Fault status encodings for TLB conflict aborts are defined for both the Short-descriptor and Long-descriptor translation table formats, see:

- [PL1 fault reporting with the Short-descriptor translation table format on page G4-4128](#)
- [PL1 fault reporting with the Long-descriptor translation table format on page G4-4129](#).

On a TLB conflict abort, the fault address register returns the address that generated the fault. That is, it returns the address that was being looked up in the TLB.

It is IMPLEMENTATION DEFINED whether a TLB conflict abort is a stage 1 abort or a stage 2 abort.

———— Note —————

- An address can hit multiple entries in the TLB if the TLB has been invalidated inappropriately, for example if TLB invalidation required by this manual has not been performed.
- A stage 2 abort cannot be generated if the Non-secure PL1&0 stage 2 address translation is disabled.

The priority of the TLB conflict abort is IMPLEMENTATION DEFINED, because it depends on the form of any TLB that can generate the abort. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.

If an address matches multiple entries in the TLB and no TLB conflict abort not generated, the resulting behavior is CONSTRAINED UNPREDICTABLE, see [CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values on page K1-5461](#). The CONSTRAINED UNPREDICTABLE behavior must not permit access to regions of memory with permissions or attributes that mean they cannot be accessed in the current Security state at the current Privilege level.

G4.9 TLB maintenance requirements

Translation Lookaside Buffers (TLBs) on page G4-4089 describes the ARM architectural provision for TLBs. Although the ARM architecture does not specify the form of any TLB structures, it does define the mechanisms by which TLBs can be maintained. The following sections describe the VMSAv8-32 TLB maintenance instructions:

- *General TLB maintenance requirements.*
- *Maintenance requirements on changing System register values* on page G4-4097.
- *Atomicity of register changes on changing virtual machine* on page G4-4098.
- *Synchronization of changes of ASID and TTBR* on page G4-4099.
- *The scope of TLB maintenance instructions* on page G4-4101.

G4.9.1 General TLB maintenance requirements

TLB maintenance instructions provide a mechanism to invalidate entries from a TLB. As stated at the start of *Translation Lookaside Buffers (TLBs)* on page G4-4089, when address translation is enabled any translation table entry that does not generate a Translation fault, an Address size fault, or an Access flag fault can be allocated to a TLB at any time. This means that software must perform TLB maintenance between updating translation table entries that apply in a particular context and accessing memory locations whose translation is determined by those entries in that context.

———— Note ————

This requirement applies to any translation table entry at any level of the translation tables, including an entry that points to further levels of the tables, provided that the entry in that level of the tables does not cause a Translation fault, an Address size fault, or an Access flag fault.

In addition to any TLB maintenance requirement, when changing the cacheability attributes of an area of memory, software must ensure that any cached copies of affected locations are removed from the caches. For more information see *Cache maintenance requirement created by changing translation table attributes* on page G4-4108.

Because a TLB never holds any translation table entry that generates a Translation fault, an Address size fault, or an Access flag fault, a change from a translation table entry that causes a Translation, Address size, or Access flag fault to one that does not fault, does not require any TLB or branch predictor invalidation.

Special considerations apply to translation table updates that change the memory type, cacheability, or output address of an entry, see *Using break-before-make when updating translation table entries* on page G4-4094.

In addition, software must perform TLB maintenance after updating the System registers if the update means that the TLB might hold information that applies to a current translation context, but is no longer valid for that context. *Maintenance requirements on changing System register values* on page G4-4097 gives more information about this maintenance requirement.

Each of the translation regimes defined in *Figure G4-1* on page G4-4024 is a different context, and:

- For the Non-secure PL1&0 regime, a change in the VMID or ASID value changes the context.
- For the Secure PL1&0 regime, a change in the ASID value changes the context.

For operation in Non-secure PL1 or PL0 modes, a change of *HCR.VM*, unless made at the same time as a change of VMID, requires the invalidation of all TLB entries for the Non-secure PL1&0 translation regime that apply to the current VMID. Otherwise, there is no guarantee that the effect of the change of *HCR.VM* is visible to software executing in the Non-secure PL1 and PL0 modes.

Any TLB maintenance instruction can affect any other TLB entries that are not locked down.

AArch32 state defines {coproc==0b1111, CRn==c8} System instructions for TLB maintenance instructions, and supports the following operations:

- Invalidate all unlocked entries in the TLB.
- Invalidate a single TLB entry, by VA, or VA and ASID for a non-global entry.
- Invalidate all TLB entries that match a specified ASID.
- Invalidate all TLB entries that match a specified VA, regardless of the ASID.
- Operations that apply across multiprocessors in the same Inner Shareable domain.

Note

An address-based TLB maintenance instruction that applies to the Inner Shareable domain does so regardless of the Shareability attributes of the address supplied as an argument to the instruction.

A TLB maintenance instruction that specifies a virtual address that would generate any MMU fault, including a virtual address that is not in the range of virtual addresses that can be translated, does not generate an abort.

EL2 provides additional TLB maintenance instructions for use in AArch32 state at PL2, and has some implications for the effect of the other TLB maintenance instructions, see [The scope of TLB maintenance instructions on page G4-4101](#).

In an implementation that includes EL3, the TLB maintenance instructions take account of the current Security state, as part of the address translation required for the TLB maintenance instruction.

Some TLB maintenance instructions are defined as operating only on instruction TLBs, or only on data TLBs. ARMv8 AArch32 state includes these instructions for backwards compatibility. However, more recent TLB maintenance instructions do not support this distinction. From the introduction of ARMv7, ARM deprecates any use of Instruction TLB maintenance instructions, or of Data TLB maintenance instructions, and developers must not rely on this distinction being maintained in future revisions of the ARM architecture.

The ARM architecture does not dictate the form in which the TLB stores translation table entries. However, for TLB invalidate instructions, the minimum size of the table entry that is invalidated from the TLB must be at least the size that appears in the translation table entry.

[The scope of TLB maintenance instructions on page G4-4101](#) describes the TLB maintenance instructions. The following subsections give more information about the general requirements for TLB maintenance:

- [Using break-before-make when updating translation table entries](#)
- [The interaction of TLB lockdown with TLB maintenance instructions on page G4-4095](#)
- [Ordering and completion of TLB maintenance instructions on page G4-4096](#)

Using break-before-make when updating translation table entries

To avoid possibly creating multiple TLB entries for the same address, and to avoid the effects of TLB caching possibly breaking coherency, ordering guarantees or uniprocessor semantics, or possibly failing to clear the exclusive monitors, the architecture requires the use of a break-before-make sequence when changing translation table entries whenever multiple threads of execution can use the same translation tables and the change to the translation table entries involves any of:

- A change of the memory type.
- A change of the cacheability attributes.
- A change of the output address (OA), if the OA of at least one of the old translation table entries and the new translation table entry is writable.
- A change to the size of block used by the translation system. This applies both:
 - When changing from a smaller size to a larger size, for example by replacing a table mapping with a block mapping in a stage 2 translation table.
 - When changing from a larger size to a smaller size, for example by replacing a block mapping with a table mapping in a stage 2 translation table.
- Creating a global entry when there might be non-global entries in a TLB that overlap with that global entry.

A break-before-make sequence on changing from an old translation table entry to a new translation table entry requires the following steps:

1. Replace the old translation table entry with an invalid entry, and execute a DSB instruction.
2. Invalidate the translation table entry with a broadcast TLB invalidation instruction, and execute a DSB instruction to ensure the completion of that invalidation.
3. Write the new translation table entry, and execute a DSB instruction to ensure that the new entry is visible.

This sequence ensures that at no time are both the old and new entries simultaneously visible to different threads of execution, and therefore the problems described at the start of this subsection cannot arise.

The interaction of TLB lockdown with TLB maintenance instructions

The precise interaction of TLB lockdown with the TLB maintenance instructions is IMPLEMENTATION DEFINED. However, the architecturally-defined TLB maintenance instructions must comply with these rules:

- The effect on locked entries of a TLB invalidate all unlocked entries instruction or a TLB invalidate by VA all ASID instruction is IMPLEMENTATION DEFINED. However, these instructions must implement one of the following options:
 - Have no effect on entries that are locked down.
 - Generate an IMPLEMENTATION DEFINED Data Abort exception if an entry is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the {coproc==0b1111, CRn==c5} fault status register definitions include a fault code for cache and TLB lockdown faults, see [Table G4-24 on page G4-4128](#) for the codes used with the Short-descriptor translation table formats, or [Table G4-25 on page G4-4130](#) for the codes used with the Long-descriptor translation table formats. In an implementation that includes EL2, if EL2 is using AArch32 and the value of HCR.TIDCP is 1, any such exceptions taken from a Non-secure PL1 mode are routed to Hyp mode, see [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-3900](#).

This permits a usage model for TLB invalidate routines, where the routine invalidates a large range of addresses, without considering whether any entries are locked in the TLB.
- The effect on locked entries of a TLB invalidate by VA instruction or a TLB invalidate by ASID match instruction is IMPLEMENTATION DEFINED. However, these instructions must implement one of the following options:
 - A locked entry is invalidated in the TLB.
 - The instruction has no effect on a locked entry in the TLB. In the case of the Invalidate single entry by VA, this means the PE treats the instruction as a NOP.
 - The instruction generates an IMPLEMENTATION DEFINED Data Abort exception if it operates on an entry that is locked down, or might be locked down. For an invalidate instruction performed in AArch32 state, the {coproc==0b1111, CRn==c5} fault status register definitions include a fault code for cache and TLB lockdown faults, see [Table G4-24 on page G4-4128](#) and [Table G4-25 on page G4-4130](#).

———— Note —————

Any implementation that uses an abort mechanism for entries that can be locked down but are not actually locked down must:

- Document the IMPLEMENTATION DEFINED instruction sequences that perform the required invalidation on entries that are not locked down.
- Implement one of the other specified alternatives for the locked entries.

ARM recommends that, when possible, such IMPLEMENTATION DEFINED instruction sequences use the architecturally-defined maintenance instructions. This minimizes the number of customized maintenance operations required.

In addition, an implementation that uses an abort mechanism for handling TLB maintenance instructions on entries that can be locked down but are not actually locked down must also provide a mechanism that ensures that no TLB entries are locked.

Similar rules apply to cache lockdown, see [The interaction of cache lockdown with cache maintenance instructions on page G3-4010](#).

The architecture does not guarantee that any unlocked entry in the TLB remains in the TLB. This means that, as a side-effect of a TLB maintenance instruction, any unlocked entry in the TLB might be invalidated.

Ordering and completion of TLB maintenance instructions

The following rules describe the relations between the memory order model and the TLB maintenance instructions:

- A TLB invalidate instruction is complete when all memory accesses using the invalidated TLB entries have been observed by all observers, to the extent that those accesses must be observed. The Shareability and Cacheability of the accessed memory locations determine the extent to which the accesses must be observed.

———— **Note** —————

For a TLB invalidate instruction that affects other PEs, the set of memory accesses that have been observed when the TLB maintenance instruction is complete must include the memory accesses from those processes that used the invalidated TLB entries.

After the TLB invalidate instruction is complete, no new memory accesses using the invalidated TLB entries will be observed by those observers.

———— **Note** —————

This requirement does not mean that speculative memory accesses cannot be performed using those entries if it is impossible to tell that those memory accesses have been observed by the observers.

-
- A TLB maintenance instruction is only guaranteed to be complete after the execution of a DSB instruction.
 - An ISB instruction, or a return from an exception, causes the effect of all completed TLB maintenance instructions that appear in program order before the ISB or return from exception to be visible to all subsequent instructions, including the instruction fetches for those instructions.
 - An exception causes all completed TLB maintenance instructions, that appear in the instruction stream before the point where the exception is taken, to be visible to all subsequent instructions, including the instruction fetches for those instructions.
 - All TLB maintenance instructions are executed in program order relative to each other.
 - The execution of a Data or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent explicit load or store instruction after both:
 - The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
 - Execution of a subsequent [Context synchronization event](#).
 - The execution of an Instruction or Unified TLB maintenance instruction is only guaranteed to be visible to a subsequent instruction fetch after both:
 - The execution of a DSB instruction to ensure the completion of the TLB maintenance instruction.
 - Execution of a subsequent [Context synchronization event](#).

In all cases in this section where a DMB or DSB is referred to, it refers to a DMB or DSB whose required access type is both loads and stores. A DSB NSH is sufficient to ensure completion of TLB maintenance instructions that apply to a single PE. A DSB ISH is sufficient to ensure completion of TLB maintenance instructions that apply to PEs in the same Inner Shareable domain.

The following rules apply when writing translation table entries. They ensure that the updated entries are visible to subsequent accesses and cache maintenance instructions.

For TLB maintenance, the translation table walk is treated as a separate observer. This means:

- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by an explicit load or store after the execution of both a DSB and an ISB.

However, the architecture guarantees that any writes to the translation tables are not seen by any explicit memory access that occurs in program order before the write to the translation tables.

- A write to the translation tables is only guaranteed to be seen by a translation table walk caused by the instruction fetch of an instruction that follows the write to the translation tables after both a DSB and an ISB.

Therefore, in a uniprocessor system, an example instruction sequence for writing a translation table entry, covering changes to the instruction or data mappings is:

```
STR rx, [Translation table entry] ; write new entry to the translation table
DSB ; ensures visibility of the new entry
Invalidate TLB entry by VA (and ASID if non-global) [page address]
Invalidate BTC
DSB ; ensure completion of the Invalidate TLB instruction
ISB ; ensure table changes visible to instruction fetch
```

G4.9.2 Maintenance requirements on changing System register values

The TLB contents can be influenced by control bits in a number of System registers. This means the TLB must be invalidated after any changes to these bits, unless the changes are accompanied by a change to the VMID or ASID that defines the context to which the bits apply. The general form of the required invalidation sequence is as follows:

```
; Change control bits in System registers
ISB ; Synchronize changes to the control bits
; Perform TLB invalidation of all entries that might be affected by the changed control bits
```

The System register changes that this applies to are:

- Any change to the [NMRR](#), [PRRR](#), [MAIR0](#), [MAIR1](#), [HMAIR0](#) or [HMAIR1](#) registers.
- Any change to the [SCTLR.AFE](#) bit, see [Changing the Access flag enable on page G4-4098](#).
- Any change to any of the [SCTLR](#).{TRE, WXN, UWXN} bits.
- Any change to the Translation table base 0 address in [TTBR0](#).
- Any change to the Translation table base 1 address in [TTBR1](#).
- Any change to [HTTBR.BADDR](#).
- Any change to [VTTBR.BADDR](#).
- Changing [TTBCR.EAE](#), see [Changing the current Translation table format on page G4-4098](#).
- In an implementation that includes EL3, any change to the [SCR.SIF](#) bit.
- In an implementation that includes EL2:
 - Any change to the [HCR.VM](#) bit.
 - Any change to [HCR.PTW](#) bit, see [Changing HCR.PTW on page G4-4098](#).
- When using the Short-descriptor translation table format:
 - Any change to the RGN, IRGN, S, or NOS fields in [TTBR0](#) or [TTBR1](#).
 - Any change to the N, EAE, PD0 or PD1 fields in [TTBCR](#)
- When using the Long-descriptor translation table format:
 - Any change to the EAE, TnSZ, ORGNn, IRGNn, SHn, or EPDn fields in the [TTBCR](#), where n is 0 or 1.
 - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the [HTCR](#).
 - Any change to the T0SZ, ORGN0, IRGN0, or SH0 fields in the [VTCR](#).

Changing the Access flag enable

In a PE that is using the Short-descriptor translation table format, it is **CONSTRAINED UNPREDICTABLE** whether the TLB caches the effect of the **SCTLR.AFE** bit on translation tables. This means that, after changing the **SCTLR.AFE** bit software must invalidate the TLB before it relies on the effect of the new value of the **SCTLR.AFE** bit, otherwise behavior is **CONSTRAINED UNPREDICTABLE**, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-5461.

Note

There is no enable bit for use of the Access flag when using the Long-descriptor translation table format.

Changing HCR.PTW

When EL2 is using AArch32 and the value of the Protected table walk bit, **HCR.PTW**, is 1, a stage 1 translation table access in the Non-secure PL1&0 translation regime, to an address that is mapped to any type of Device memory by its stage 2 translation, generates a stage 2 Permission fault. A TLB associated with a particular VMID might hold entries that depend on the effect of **HCR.PTW**. Therefore, if the value of **HCR.PTW** is changed without a change to the VMID value, all TLB entries associated with the current VMID must be invalidated before executing software in a Non-secure PL1 or PL0 mode. If this is not done, behavior is **CONSTRAINED UNPREDICTABLE**, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-5461.

Changing the current Translation table format

The effect of changing **TTBCR.EAE** when executing in the translation regime affected by **TTBCR.EAE** with any stage of address translation for that translation regime enabled is **CONSTRAINED UNPREDICTABLE**. This means that, when **TTBCR.EAE** is changed for a given context, the TLB must be invalidated before resuming execution in that context, otherwise the effect is **CONSTRAINED UNPREDICTABLE**, see *CONSTRAINED UNPREDICTABLE behaviors due to caching of control or data values* on page K1-5461.

G4.9.3 Atomicity of register changes on changing virtual machine

From the viewpoint of software executing in a Non-secure PL1 or PL0 mode, when there is a switch from one virtual machine to another, the registers that control or affect address translation must be changed atomically. This applies to the registers for:

- Non-secure PL1&0 stage 1 address translations. This means that all of the following registers must change atomically:
 - **PRRR** and **NMRR**, if using the Short-descriptor translation table format.
 - **MAIR0** and **MAIR1**, if using the Long-descriptor translation table format.
 - **TTBR0**, **TTBR1**, **TTBCR**, **DACR**, and **CONTEXTIDR**.
 - The **SCTLR**.
- Non-secure PL1&0 stage 2 address translations. When EL2 is using AArch32, this means that all of the following registers and register fields must change atomically:
 - **VTBR** and **VTCR**.
 - **HMAIR0** and **HMAIR1**.
 - The **HSCTLR**.

Note

Only some bits of **SCTLR** affect the stage 1 translation, and only some bits of **HSCTLR** affect the stage 2 translation. However, in each case, changing these bits requires a write to the register, and that write must be atomic with the other register updates.

These registers apply to execution in Non-secure PL1&0 modes. However, when updated as part of a switch of virtual machines they are updated by software executing in Hyp mode. This means the registers are *out of context* when they are updated, and no synchronization precautions are required.

Note

By contrast, a translation table change associated with a change of ASID, made by software executing at PL1, can require changes to registers that are *in context*. [Synchronization of changes of ASID and TTBR](#) describes appropriate precautions for such a change.

Software executing in Hyp mode, or in Secure state, must not use the registers associated with the Non-secure PL1&0 translation regime for speculative memory accesses.

G4.9.4 Synchronization of changes of ASID and TTBR

A common virtual memory management requirement is to change the ASID and [TTBR](#) together to associate the new ASID with different translation tables, without any change to the current translation regime. When using the Short-descriptor translation table format, different registers hold the ASID and the translation table base address, meaning these two values cannot be updated atomically. Since a PE can perform a speculative memory access at any time, this lack of atomicity is a problem that software must address. Such a change is complicated by:

- The depth of speculative fetch being IMPLEMENTATION DEFINED.
- The use of branch prediction.

When using the Short-descriptor translation table format, the virtual memory management operations must ensure the synchronization of changes of the ContextID and the translation table registers. For example, some or all of the TLBs, branch predictors, and other caching of ASID and translation information might become corrupt with invalid translations. Synchronization is required to avoid either:

- The old ASID being associated with translation table walks from the new translation tables.
- The new ASID being associated with translation table walks from the old translation tables.

There are a number of possible solutions to this problem, and the most appropriate approach depends on the system. [Example G4-3](#), [Example G4-4 on page G4-4100](#), and [Example G4-5 on page G4-4100](#) describe three possible approaches.

Note

Another instance of the synchronization problem occurs if a branch is encountered between changing the ASID and performing the synchronization. In this case the value in the branch predictor might be associated with the incorrect ASID. Software can address this possibility using any of these approaches, but instead software might be written in a way that avoids such branches.

Example G4-3 Using a reserved ASID to synchronize ASID and TTBR changes

In this approach, a particular ASID value is reserved for use by the operating system, and is used only for the synchronization of the ASID and [TTBR](#). This example uses the value of 0 for this purpose, but any value could be used.

This approach can be used only when the size of the mapping for any given virtual address is the same in the old and new translation tables.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change ASID to 0
ISB
Change TTBR
ISB
Change ASID to new value
```

This approach ensures that any non-global pages fetched at a time when it is uncertain whether the old or new translation tables are being accessed are associated with the unused ASID value of 0. Since the ASID value of 0 is not used for any normal operations these entries cannot cause corruption of execution.

Example G4-4 Using translation tables containing only global mappings when changing the ASID

A second approach involves switching the translation tables to a set of translation tables that only contain global mappings while switching the ASID.

The maintenance software uses the following sequence, that must be executed from memory marked as global:

```
Change TTBR to the global-only mappings
ISB
Change ASID to new value
ISB
Change TTBR to new value
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

This approach works without the need for TLB invalidations in systems that have caching of intermediate levels of translation tables, as described in *General TLB maintenance requirements* on page G4-4093, provided that the translation tables containing only global mappings have only level 1 translation table entries of the following kinds:

- Entries that are global.
- Pointers to level 2 tables that hold only global entries, and that are the same level 2 tables that are used for accessing global entries by both:
 - The set of translation tables that were used under the old ASID value.
 - The set of translation tables that will be used with the new ASID value.
- Invalid level 1 entries.

In addition, all sets of translation tables in this example should have the same Shareability and Cacheability attributes, as held in the `TTBR0.{ORGN, IRGN}` or `TTBR1.{ORGN, IRGN}` fields.

If these rules are not followed, then the implementation might cache level 1 translation table entries that require explicit invalidation.

Example G4-5 Disabling non-global mappings when changing the ASID

In systems where only the translation tables indexed by `TTBR0` hold non-global mappings, maintenance software can use the `TTBCR.PD0` field to disable use of `TTBR0` during the change of ASID. This means the system does not require a set of global-only mappings.

The maintenance software uses the following sequence, that must be executed from a memory region with a translation that is accessed using the base address in the `TTBR1` register, and is marked as global:

```
Set TTBCR.PD0 = 1
ISB
Change ASID to new value
Change TTBR to new value
ISB
Set TTBCR.PD0 = 0
```

This approach ensures that no non-global pages can be fetched at a time when it is uncertain whether the old or new ASID value will be used.

When using the Long-descriptor translation table format, `TTBCR.A1` holds the number, 0 or 1, of the TTBR that holds the current ASID. This means the current `TTBR` can also hold the current ASID, and the current translation table base address and ASID can be updated atomically when:

- `TTBR0` is the only `TTBR` being used. `TTBCR.A1` must be set to 0.

- **TTBR0** points to the only translation tables that hold non-global entries, and **TTBCR.A1** is set to 0.
- **TTBR1** points to the only translation tables that hold non-global entries, and **TTBCR.A1** is set to 1.

In these cases, software can update the current translation table base address and ASID atomically, by updating the appropriate TTBR, and does not require a specific routine to ensure synchronization of the change of ASID and base address.

However, in all other cases using the Long-descriptor format, the synchronization requirements are identical to those when using the Short-descriptor formats, and the examples in this section indicate how synchronization might be achieved.

———— **Note** —————

When using the Long-descriptor translation table format, **CONTEXTIDR.ASID** has no significance for address translation, and is only an extension of the Context ID value.

G4.9.5 The scope of TLB maintenance instructions

TLB maintenance instructions provide a mechanism for invalidating entries from TLB caching structures, to ensure that changes to the translation tables are reflected correctly in the TLB caching structures. To support TLB maintenance in multiprocessor systems, there are maintenance operations that apply to the TLBs of all PEs in the same Inner Shareable domain.

The architecture permits the caching of any translation table entry that has been returned from memory without a fault and that does not, itself, cause a Translation Fault, an Address size fault, or an Access Flag fault. This means the TLB:

- Cannot hold an entry that, when used for a translation table lookup, causes a Translation fault, an Address size fault, or an Access Flag fault.
- Can hold an entry for a translation table lookup for a translation that causes a Translation Fault, an Address size fault, or an Access Flag fault at a subsequent level of translation table lookup. For example, it can hold an entry for the level 1 lookup of a translation that causes a Translation fault, an Address size fault, or an Access Flag fault at level 2 or level 3 of lookup.

This means that entries cached in the TLB can include:

- Translation table entries that point to a subsequent table to be used in the current stage of translation.
- In an implementation that includes EL2:
 - Stage 2 translation table entries that are used as part of a stage 1 translation table walk.
 - Stage 2 translation table entries for translating the output address of a stage 1 translation.

Such entries might be held in intermediate TLB caching structures that are distinct from the data caches, in that they are not required to be invalidated as the result of writes of the data. The architecture makes no restriction on the form of these intermediate TLB caching structures.

The architecture does not intend to restrict the form of TLB caching structures used for holding translation table entries. In particular for translation regimes that involve two stages of translation, it recognizes that such caching structures might contain:

- At any level of the translation table walk, entries containing information from stage 1 translation table entries.
- In an implementation that includes EL2:
 - At any level of the translation table walk, entries containing information from stage 2 translation table entries.
 - At any level of the translation table walk, entries combining information from both stage 1 and stage 2 translation table entries.

———— **Note** —————

For the purpose of TLB maintenance, the term *TLB entry* denotes any structure, including temporary working registers in translation table walk hardware, that holds a translation table entry.

Where a TLB maintenance instruction is:

- Required to apply to stage 1 entries, then it must apply to any cached entry in the caching structures that includes any stage 1 information that would be used to translate the address being invalidated, including any entry that combines information from both stage 1 and stage 2 translation table entries.

———— **Note** —————

- Where stage 1 information has been cached in multiple TLB entries, as could occur from splintering a page when caching in the TLB, then the invalidation must apply to each cached entry containing stage 1 information from the page that is used to translate the address being invalidated, regardless of whether or not that cached entry would be used to translate the address being invalidated.
- As stated in *Global and process-specific translation table entries on page G4-4089*, translation table entries from levels of translation other than the final level are treated as being non-global. ARM expects that, in at least some implementations, cached copies of levels of the translation table walk other than the last level are tagged with their ASID, regardless of whether the final level is global. This means that TLB invalidations that involve the ASID require the ASID to match such entries to perform the required invalidation.

-
- Required to apply to stage 2 entries only, then:
 - It is not required to apply to caching structures that combine stage 1 and stage 2 translation table entries.
 - It must apply to caching structures that contain information only from stage 2 translation table entries.
 - Required to apply to both stage 1 and stage 2 entries, then it must apply to any entry in the caching structures that includes information from either a stage 1 translation table entry or a stage 2 translation table entry, including any entry that combines information from both stage 1 and stage 2 translation table entries.

Table G4-22 on page G4-4103 summarizes the required effect of the preferred TLB operations, for execution in AArch32 state, that operate only on TLBs on the PE that executes the instruction. Additional TLB operations:

- Apply across all PEs in the same Inner Shareable domain. Each operation shown in the table has an Inner Shareable equivalent, identified by an IS suffix. For example, the Inner Shareable equivalent of **TLBIALL** is **TLBIALLIS**. See also *EL2 upgrading of TLB maintenance instructions on page G4-4104*.
- Can apply to separate Instruction or Data TLBs, as indicated by a footnote to the table. ARM deprecates any use of these operations.

———— **Note** —————

- The architecture permits a TLB invalidation operation to affect any unlocked entry in the TLB. Table G4-22 on page G4-4103 defines only the entries that each operation must invalidate.
- All TLB operations, including those that operate on a VA match, operate regardless of the value of **SCTLR.M**.

When interpreting the table:

Related operations Each operation description applies also to any equivalent operation that either:

- Applies to all PEs in the same Inner Shareable domain.
- Applies only to a data TLB, or only to an instruction TLB.

So, for example, the **TLBIALL** description applies also to **TLBIALLIS**, **ITLBIALL**, and **DTLBIALL**.

TLB maintenance instructions, functional group on page G4-4202 lists all of the TLB maintenance instructions.

Matches the VA Means the VA argument for the operation must match the VA value in the TLB entry.

Matches the ASID Means the ASID argument for the operation must match the ASID in use when the TLB entry was assigned.

Matches the current VMID

Means the current VMID must match the VMID in use when the TLB entry was assigned. The dependency on the VMID applies even when the value of `HCR.VM` is 0, including situations where there is no use of virtualization. However, `VTTBR.VMID` resets to zero, meaning there is a valid VMID from reset.

Execution at PL2 Descriptions of operations at PL2 apply only to implementations that include EL2.

For the definitions of the translation regimes referred to in the table see *About VMSAv8-32 on page G4-4022*.

Table G4-22 Effect of the TLB maintenance instructions

| Operation | Executed from | | Effect, must invalidate any entry that matches all stated conditions |
|--------------------------|---------------|------------|--|
| | State | Mode | |
| TLBIALL ^a | Secure | PL1 | All entries for the Secure PL1&0 translation regime. That is, all entries that were allocated in Secure state. |
| | Non-secure | PL1 | All entries for stage 1 of the Non-secure PL1&0 translation regime that match the current VMID. |
| | | Hyp | All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime that match the current VMID. |
| TLBIMVA ^a | Secure | PL1 | Any entry for the Secure PL1&0 translation regime that both: <ul style="list-style-type: none"> Matches the VA argument. Matches the ASID argument, or is global. |
| | Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime to which all of the following apply. The entry: <ul style="list-style-type: none"> Matches the VA argument. Matches the ASID argument, or is global. Matches the current VMID. |
| TLBIASID ^a | Secure | PL1 | Any entry for the Secure PL1&0 translation regime that matches the specified ASID and either: <ul style="list-style-type: none"> Is from a level of lookup above the final level. Is a non-global entry from the final level of lookup. |
| | Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: <ul style="list-style-type: none"> Matches the specified ASID and either: <ul style="list-style-type: none"> Is from a level of lookup above the final level. Is a non-global entry from the final level of lookup. Matches the current VMID. |
| TLBIMVAA | Secure | PL1 | Any entry for the Secure PL1&0 translation regime that matches the VA argument. |
| | Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that both: <ul style="list-style-type: none"> Matches the VA argument. Matches the current VMID. |
| TLBIALLNSNH ^b | Secure | Monitor | All entries for stage 1 or stage 2 of the Non-secure PL1&0 translation regime, regardless of the associated VMID. |
| | Non-secure | Hyp | |
| TLBIALLH ^b | Secure | Monitor | All entries for the Non-secure PL2 translation regime. That is, any entry that was allocated in Non-secure state from Hyp mode. |
| | Non-secure | Hyp | |

Table G4-22 Effect of the TLB maintenance instructions (continued)

| Operation | Executed from | | Effect, must invalidate any entry that matches all stated conditions |
|----------------------------|---------------|----------------------|--|
| | State | Mode | |
| TLBIMVAL | Secure | PL1 | Any entry for stage 1 of the Secure PL1&0 translation regime that is from the last level of the translation table walk and both: <ul style="list-style-type: none"> Matches the VA argument. Matches the ASID argument, or is global. |
| | Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that is from the last level of the translation table walk and to which all of the following apply. The entry: <ul style="list-style-type: none"> Matches the VA argument. Matches the ASID argument, or is global. Matches the current VMID. |
| TLBIMVAAL | Secure | PL1 | Any entry for stage 1 of the Secure PL1&0 translation regime that is from the last level of the translation table walk and matches the VA argument. |
| | Non-secure | PL1 or Hyp | Any entry for stage 1 of the Non-secure PL1&0 translation regime that is from the last level of the translation table walk and both: <ul style="list-style-type: none"> Matches the VA argument. Matches the current VMID. |
| TLBIMVAH ^b | Secure | Monitor | Any entry for the Non-secure PL2 translation regime that matches the VA argument. |
| | Non-secure | Hyp | |
| TLBIMVALH ^b | Secure | Monitor | Any entry for the Non-secure PL2 translation regime that is from the last level of the translation table walk and matches the VA argument. |
| | Non-secure | Hyp | |
| TLBIIPAS2 ^{b, c} | Secure | Monitor ^d | Any entry for stage 2 of the PL1&0 translation regime that both: <ul style="list-style-type: none"> Matches the IPA argument. Matches the current VMID. |
| | Non-secure | Hyp | |
| TLBIIPAS2L ^{b, c} | Secure | Monitor ^d | Any entry for stage 2 of the PL1&0 translation regime that is from the last level of translation and both: <ul style="list-style-type: none"> Matches the IPA argument. Matches the current VMID. |
| | Non-secure | Hyp | |

- a. The architecture defines variants of these operations that apply only to instruction TLBs, and only to data TLBs. ARM deprecates any use of these variants. For more information, see the referenced description of the operation.
- b. Available only in an implementation that includes EL2. See also [EL2 upgrading of TLB maintenance instructions](#).
- c. This instruction is CONSTRAINED UNPREDICTABLE if executed in any AArch32 Secure privileged mode, see [Hyp mode TLB maintenance instructions on page K1-5476](#).
- d. This instruction executes as a NOP when SCR.NS == 0.

EL2 upgrading of TLB maintenance instructions

In an implementation that includes EL2, when the value of HCR.FB is 1, the TLB maintenance instructions that are not broadcast across the Inner Shareable domain are upgraded to operate across the Inner Shareable domain when performed in a Non-secure PL1 mode. For example, when the value of HCR.FB is 1, a TLBIMVA operation performed in a Non-secure PL1 mode operates as a TLBIMVAIS operation.

TLB maintenance with different translation granule sizes

If a TLB maintenance instruction specifying a virtual address affecting the PL2 translation regime is broadcast from a PE using AArch32 to a PE using AArch64 using a translation granule size that is different from the AArch32 translation granule size for that same translation regime, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

If a TLB maintenance instruction specifying a virtual address affecting the PL1 translation regime is broadcast from a PE using AArch32 using one translation granule size for that translation regime for a particular ASID, VMID (if applicable), and Security state, to a PE using AArch64 where EL1 for the same ASID, VMID (if applicable), and Security state, is using a translation granule size that is different from the AArch32 translation granule size, the TLB maintenance instruction is not required to perform any invalidation on the recipient PE.

G4.10 Caches in VMSAv8-32

The ARM architecture describes the required behavior of an implementation of the architecture. As far as possible it does not restrict the implemented microarchitecture, or the implementation techniques that might achieve the required behavior.

Maintaining this level of abstraction is difficult when describing the relationship between memory address translation and caches, especially regarding the indexing and tagging policy of caches. This section:

- Summarizes the architectural requirements for the interaction between caches and memory translation.
- Gives some information about the likely implementation impact of the required behavior.

The following sections give this information:

- [Data and unified caches](#).
- [Instruction caches](#).

In addition [Cache maintenance requirement created by changing translation table attributes on page G4-4108](#) describes the cache maintenance required after updating the translation tables to change the attributes of an area of memory.

For more information about cache maintenance see:

- [AArch32 cache and branch predictor support on page G3-3989](#). This section describes the ARM cache maintenance instructions.
- [Cache maintenance instructions, functional group on page G4-4201](#). This section summarizes the System register encodings used for these operations when executing in AArch32 state.

G4.10.1 Data and unified caches

For data and unified caches, the use of memory address translation is entirely transparent to any data access other than as described in [Mismatched memory attributes on page E2-2352](#).

This means that the behavior of accesses from the same observer to different VAs, that are translated to the same PA with the same memory attributes, is fully coherent. This means these accesses behave as follows, regardless of which VA is accessed:

- Two writes to the same PA occur in program order.
- A read of a PA returns the value of the last successful write to that PA.
- A write to a PA that occurs, in program order, after a read of that PA, has no effect on the value returned by that read.

The memory system behaves in this way without any requirement to use barrier or cache maintenance instructions.

In addition, if cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

These properties are consistent with implementing all caches that can handle data accesses as *Physically-indexed, physically-tagged* (PIPT) caches.

G4.10.2 Instruction caches

In the ARM architecture, an instruction cache is a cache that is accessed only as a result of an instruction fetch. Therefore, an instruction cache is never written to by any load or store instruction executed by the PE.

The ARM architecture supports three different behaviors for instruction caches. For ease of reference and description these are identified by descriptions of the associated expected implementation, as follows:

- PIPT instruction caches.
- *Virtually-indexed, physically-tagged* (VIPT) instruction caches.
- ASID and VMID tagged *Virtually-indexed, virtually-tagged* (VIVT) instruction caches.

In AArch32 state, the CTR identifies the form of the instruction caches, see [CTR, Cache Type Register](#) on page G6-4293.

The following subsections describe the behavior associated with these cache types, including any occasions where explicit cache maintenance is required to make the use of memory address translation transparent to the instruction cache:

- [PIPT instruction caches](#).
- [VIPT instruction caches](#).
- [ASID and VMID tagged VIVT instruction caches](#).
- [The IVIPT architecture Extension](#) on page G4-4108.

Note

For software to be portable between implementations that might use any of PIPT instruction caches, VIPT instruction caches, or ASID and VMID tagged VIVT instruction caches, the software must invalidate the instruction cache whenever any condition occurs that would require instruction cache maintenance for at least one of the instruction cache types.

PIPT instruction caches

For PIPT instruction caches, the use of memory address translation is entirely transparent to all instruction fetches other than as described in [Mismatched memory attributes](#) on page E2-2352.

If cache maintenance is performed on a memory location, the effect of that cache maintenance is visible to all aliases of that physical memory location.

An implementation that provides PIPT instruction caches implements the IVIPT Extension, see [The IVIPT architecture Extension](#) on page G4-4108.

VIPT instruction caches

For VIPT instruction caches, the use of memory address translation is transparent to all instruction fetches other than for the effect of memory address translation on instruction cache invalidate by address operations or as described in [Mismatched memory attributes](#) on page E2-2352.

Note

Cache invalidation is the only cache maintenance instruction that can be performed on an instruction cache.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from a VIPT instruction cache is to invalidate the entire instruction cache.

An implementation that provides VIPT instruction caches implements the IVIPT Extension, see [The IVIPT architecture Extension](#) on page G4-4108.

ASID and VMID tagged VIVT instruction caches

For ASID and VMID tagged VIVT instruction caches, if the instructions at any virtual address change, for a given translation regime and a given ASID and VMID, as appropriate, then instruction cache maintenance is required to ensure that the change is visible to subsequent execution. This maintenance is required when writing new values to instruction locations. It can also be required as a result of any of the following situations that change the translation of a virtual address to a physical address, if, as a result of the change to the translation, the instructions at the virtual addresses change:

- For any translation regime other than the Non-secure PL1&0 translation regime, enabling or disabling stage 1 translations.

- For the Non-secure PL1&0 translation regime:
 - When stage 2 translations are enabled, enabling or disabling stage 1 translations unless accompanied by a change of VMID.
 - When stage 2 translations are disabled, enabling or disabling stage 1 translations.
 - Enabling or disabling stage 2 translations.
- Writing new mappings to the translation tables.
- In AArch32 state, any change to the [TTBR0](#), [TTBR1](#), or [TTBCR](#) registers, unless:
 - For a change to the Secure PL1&0 translation regime, the change is accompanied by a change to the ASID.
 - For a change to the stage 1 translations of the Non-secure PL1&0 translation regime, the change is accompanied by a change to the ASID or a change to the VMID.
- In AArch32 state, any change to the [VTTBR](#) or [VTCR](#) registers, unless accompanied by a change to the VMID.

———— **Note** —————

For ASID and VMID tagged VIVT instruction caches only, for a given translation regime and a given ASID and VMID, as appropriate, invalidation is not required if a change to the translations is such that the instructions associated with the non-faulting translations of a virtual address remain unchanged through the change to the translations, even if the physical locations being mapped to by the changed translation have been written as part of changing the translation.

Examples of situations where this might occur include:

- Copy-on-Write.
- Demand Paging of memory locations to/from disk.

This does not apply for VIPT or PIPT instruction caches, because those caches hold copies of physical addresses, and therefore must be invalidated when the contents are written to, to avoid the use of stale entries.

If instruction cache invalidation by address is performed on a memory location, the effect of that invalidation is visible only to the virtual address supplied with the operation. The effect of the invalidation might not be visible to any other virtual address aliases of that physical memory location.

The only architecturally-guaranteed way to invalidate all aliases of a physical address from an ASID and VMID tagged VIVT instruction cache is to invalidate the entire instruction cache.

The IVIPT architecture Extension

An implementation in which the instruction cache exhibits the behaviors described in [PIPT instruction caches on page G4-4107](#), or those described in [VIPT instruction caches on page G4-4107](#), is said to implement the *IVIPT Extension* to the ARM architecture.

The formal definition of the IVIPT Extension to the ARM architecture is that it reduces the instruction cache maintenance requirement to the following condition:

- Instruction cache maintenance is required only after writing new data to a physical address that holds an instruction.

G4.10.3 Cache maintenance requirement created by changing translation table attributes

Any change to the translation tables to change the attributes of an area of memory can require maintenance of the translation tables, as described in [General TLB maintenance requirements on page G4-4093](#). If the change affects the cacheability attributes of the area of memory, including any change between Write-Through and Write-Back attributes, software must ensure that any cached copies of affected locations are removed from the caches, typically

by cleaning and invalidating the locations from the levels of cache that might hold copies of the locations affected by the attribute change. Any of the following changes to the inner cacheability or outer cacheability attribute creates this maintenance requirement:

- Write-Back to Write-Through.
- Write-Back to Non-cacheable.
- Write-Through to Non-cacheable.
- Write-Through to Write-Back.

The cache clean and invalidate avoids any possible coherency errors caused by mismatched memory attributes.

Similarly, to avoid possible coherency errors caused by mismatched memory attributes, the following sequence must be followed when changing the Shareability attributes of a cacheable memory location:

1. Make the memory location Non-cacheable, Outer Shareable.
2. Clean and invalidate the location from them cache.
3. Change the Shareability attributes to the required new values.

G4.11 VMSAv8-32 memory aborts

In a VMSAv8-32 implementation, the following mechanisms cause a PE to take an exception on a failed memory access:

| | |
|------------------------|---|
| Debug exception | An exception caused by the debug configuration, see Chapter G2 AArch32 Self-hosted Debug . |
| Alignment fault | An Alignment fault is generated if the address used for a memory access does not have the required alignment for the operation. For more information see Unaligned data access on page E2-2323 and Alignment faults on page G4-4117 . |
| MMU fault | An MMU fault is a fault generated by the fault checking sequence for the current translation regime. See MMU faults in AArch32 state on page G4-4118 . |
| External abort | Any memory system fault other than a Debug exception, an Alignment fault, or an MMU fault. |

Collectively, these mechanisms are called *aborts*. [Chapter G2 AArch32 Self-hosted Debug](#) and [Chapter H3 Halting Debug Events](#) describe Debug exceptions, and the remainder of this section describes Alignment faults, MMU faults, and External aborts.

The exception generated on a synchronous memory abort:

- On an instruction fetch is called the Prefetch Abort exception.
- On a data access is called the Data Abort exception.

———— Note ————

The Prefetch Abort exception applies to any synchronous memory abort on an instruction fetch. It is not restricted to speculative instruction fetches.

In AArch32 state, asynchronous memory aborts are a type of External abort, and are treated as a type of Data Abort exception.

The following sections describe the abort mechanisms:

- [Routing of aborts taken to AArch32 state](#).
- [VMSAv8-32 MMU fault terminology on page G4-4113](#).
- [The MMU fault-checking sequence on page G4-4113](#).
- [Alignment faults on page G4-4117](#).
- [MMU faults in AArch32 state on page G4-4118](#).
- [External abort on a translation table walk on page G4-4120](#).
- [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#).

An access that causes an abort is said to be aborted. On an abort, System registers are used to record context information. For more information see [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#).

G4.11.1 Routing of aborts taken to AArch32 state

A memory abort is either a Data Abort exception or a Prefetch Abort exception. When executing in AArch32 state, depending on the cause of the abort, and possibly on configuration settings, an abort is taken either:

- To the Exception level of the PE mode from which the abort is taken. In this case the abort is taken to AArch32 state.
- To a higher Exception level. In this case the Exception level to which the abort is taken is either:
 - Using AArch32. In this case, this chapter describes how the abort is handled.
 - Using AArch64. In this case, [Chapter D4 The AArch64 Virtual Memory System Architecture](#) describes how the abort is handled.

For an abort taken to an Exception level that is using AArch32, the mode to which a memory abort is taken depends on the reason for the exception, the mode the PE is in when it takes the exception, and configuration settings, as follows:

Memory aborts taken to Monitor mode

If an implementation includes EL3, when the value of `SCR.EA` is 1, all External aborts are taken to EL3, and if EL3 is using AArch32 they are taken to Monitor mode. This applies to aborts taken from Secure modes and from Non-secure modes. For more information see [Asynchronous exception routing controls on page G1-3841](#).

Note

- Although the referenced section mostly describes the routing of asynchronous exceptions, it includes the `SCR.EA` control that applies to both synchronous external aborts and SError interrupts.
- The `SCR` is implemented only as part of EL3.

Memory aborts taken to Secure Abort mode

If an implementation includes EL3, when the PE is executing in Secure state, all memory aborts that are not routed to EL3 are taken to Secure Abort mode.

Note

The only memory aborts that can be routed to Monitor mode are External aborts.

Memory aborts taken to Hyp mode

If an implementation includes EL2, when the PE is executing in Non-secure state, the following aborts are taken to EL2. If EL2 is using AArch32 this means they are taken to Hyp mode:

- Alignment faults taken:
 - When the PE is in Hyp mode.
 - When the PE is in a Non-secure PL1 or PL0 mode and the exception is generated because the Non-secure PL1&0 stage 2 translation identifies the target of an unaligned access as any type of Device memory.
 - When the PE is in Non-secure User mode and `HCR.TGE` is set to 1. For more information see [Abort exceptions, when the value of HCR.TGE is 1 on page G1-3830](#).
- When the PE is using the Non-secure PL1&0 translation regime:
 - MMU faults from stage 2 translations, for which the stage 1 translation did not cause an MMU fault.
 - Any abort taken during the stage 2 translation of an address accessed in a stage 1 translation table walk that is not routed to Secure Monitor mode, see [Stage 2 fault on a stage 1 translation table walk on page G4-4117](#).
- When the PE is using the Non-secure PL2 translation regime, MMU faults from stage 1 translations.

Note

The Non-secure PL2 translation regime has only one stage of translation.

- External aborts, if **SCR.EA** is set to 0 and any of the following applies:
 - The PE was executing in Hyp mode when it took the exception.
 - The PE was executing in a Non-secure PL0 or PL1 mode when it took the exception, the abort is asynchronous, and **HCR.AMO** is set to 1. For more information see [Asynchronous exception routing controls on page G1-3841](#).
 - The PE was executing in the Non-secure User mode when it took the exception, the abort is synchronous, and **HCR.TGE** is set to 1. For more information see [Abort exceptions, when the value of HCR.TGE is 1 on page G1-3830](#).
 - The abort occurred on a stage 2 translation table walk.
- Debug exceptions, if **HDCR.TDE** is set to 1. For more information, see [Routing debug exceptions to EL2 on page G1-3833](#).

Memory aborts taken to Non-secure Abort mode

In an implementation that does not include EL3, all memory aborts that are taken to an Exception level that is using AArch32 are taken to Abort mode.

Otherwise, when the PE is executing in Non-secure state, the following aborts are taken to Non-secure Abort mode:

- When the PE is in a Non-secure PL1 or PL0 mode, Alignment faults taken for any of the following reasons:
 - **SCTLR.A** is set to 1.
 - An instruction that does not support unaligned accesses is committed for execution, and the instruction accesses an unaligned address.
 - The PL1&0 stage 1 translation identifies the target of an unaligned access as any type of Device memory.

Note

In an implementation that does not include EL2, this case results in a **CONSTRAINED UNPREDICTABLE** memory access, see [Cases where unaligned accesses are CONSTRAINED UNPREDICTABLE on page E2-2324](#) and [Loads and Stores to unaligned locations on page K1-5458](#).

If an implementation includes EL2 and the PE is in Non-secure User mode, these exceptions are taken to Abort mode only if the value of **HCR.TGE** is 0.

- When the PE is using the Non-secure PL1&0 translation regime, an MMU fault from a stage 1 translation.
- External aborts, if all of the following apply:
 - The abort is not on a stage 2 translation table walk.
 - The PE is not in Hyp mode.
 - The value of **SCR.EA** is 0.
 - The abort is asynchronous, and **HCR.AMO** is set to 0.
 - The abort is synchronous, and **HCR.TGE** is set to 0.
- Virtual Aborts, see [Virtual exceptions when an implementation includes EL2 on page G1-3839](#).
- When the value of **HDCR.TDE** is 0, Debug exceptions. For more information, see [Routing debug exceptions to EL2 on page G1-3833](#).

Note

If EL0 is using AArch32 and EL1 is using AArch64 then any of these memory aborts taken from User mode are taken to EL1 as described in [Chapter D4 The AArch64 Virtual Memory System Architecture](#).

Memory aborts with IMPLEMENTATION DEFINED behavior

In addition, a PE can generate an abort for an IMPLEMENTATION DEFINED reason associated with lockdown. In an implementation that includes EL2, whether such an abort is taken to Non-secure Abort mode or is taken to EL2 is IMPLEMENTATION DEFINED, and an implementation might include a mechanism to select whether the abort is routed to Non-secure Abort mode or to EL2.

When the PE is in a Non-secure mode other than Hyp mode, if multiple factors cause an Alignment fault, the abort is taken to Non-secure Abort mode if any of the factors require the abort to be taken to Abort mode. For example, if the `SCTLR.A` bit is set to 1, and the access is an unaligned access to an address that the stage 2 translation tables mark as Device-nGnRnE, then the abort is taken to Non-secure Abort mode.

For more information see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#).

G4.11.2 VMSAv8-32 MMU fault terminology

The ARMv7 Large Physical Address Extension introduced new terminology for faults on a stage of address translation, to provide consistent terminology across all implementations. [Table G4-23](#) shows the terminology used in this manual for an MMU faults, compared with older ARM documentation. The current terms are the same for faults that occur with the Short-descriptor translation table format and with the Long-descriptor format, and also apply to faults in a level 3 lookup when using the Long-descriptor translation table format.

Table G4-23 MMU fault terminology

| Current term | Old term | Note |
|---------------------------|---------------------------|---|
| Level 1 Translation fault | Section Translation fault | - |
| Level 2 Translation fault | Page Translation fault | - |
| Level 3 Translation fault | - | Long-descriptor translation table format only. |
| Level 1 Access flag fault | Section Access flag fault | - |
| Level 2 Access flag fault | Page Access flag fault | - |
| Level 3 Access flag fault | - | Long-descriptor translation table format only. |
| Level 1 Domain fault | Section Domain fault | Short-descriptor translation table format only, except for reporting faults on address translation instructions in the 64-bit <code>PAR</code> , see Determining the PAR format on page G4-4145 . Cannot occur at level 3. |
| Level 2 Domain fault | Page Domain fault | |
| Level 1 Permission fault | Section Permission fault | - |
| Level 2 Permission fault | Page Permission fault | - |
| Level 3 Permission fault | - | Long-descriptor translation table format only. |

In an implementation that includes EL2, MMU faults are also classified by the translation stage at which the fault is generated. This means that a memory access from a Non-secure PL1 or PL0 mode can generate:

- A stage 1 MMU fault, for example, a stage 1 Translation fault.
- A stage 2 MMU fault, for example, a stage 2 Translation fault.

G4.11.3 The MMU fault-checking sequence

This section describes the MMU checks made for the memory accesses required for instruction fetches and for explicit memory accesses:

- If an instruction fetch faults it generates a Prefetch Abort exception.
- If an data memory access faults it generates a Data Abort exception.

For more information about Prefetch Abort exceptions and Data Abort exceptions see [Handling exceptions that are taken to an Exception level using AArch32 on page G1-3812](#).

In VMSAv8-32, all memory accesses require VA to PA translation. Therefore, when a corresponding stage of address translation is enabled, each access requires a lookup of the translation table descriptor for the accessed VA. For more information, see [Translation tables on page G4-4035](#) and subsequent sections of this chapter. MMU fault checking is performed for each level of translation table lookup. If an implementation includes EL2 and is operating in Non-secure state, MMU fault checking is performed for each stage of address translation.

Note

In an implementation that includes EL2, if a PE is executing in Non-secure state, the operating system or similar Non-secure system software defines the stage 1 translation tables in the IPA address space, and typically is unaware of the stage 2 translation from IPA to PA. However, each Non-secure stage 1 translation table access is subject to stage 2 address translation, and might be faulted at that stage.

The MMU fault checking sequence is largely independent of the translation table format, as the figures in this section show. The differences are:

When using the Short-descriptor format

- There are one or two levels of lookup.
- Lookup always starts at level 1.
- The final level of lookup checks the Domain field of the descriptor and:
 - Faults if there is no access to the Domain.
 - Checks the access permissions only for Client domains.

When using the Long-descriptor format

- There are one, two, or three levels of lookup.
- Lookup starts at either level 1 or level 2.
- Domains are not supported. All accesses are treated as Client domain accesses.

The fault-checking sequence shows a translation from an Input address to an Output address. For more information about this terminology, see [About address translation for VMSAv8-32 on page G4-4026](#).

Note

The descriptions in this section do not include the possibility that the attempted address translation generates a TLB conflict abort, as described in [TLB conflict aborts on page G4-4091](#).

[MMU faults in AArch32 state on page G4-4118](#) describes the faults that an MMU fault-checking sequence can report.

[Figure G4-17 on page G4-4115](#) shows the process of fetching a descriptor from the translation table. For the top-level fetch for any translation, the descriptor is fetched only if the input address passes any required alignment check. As the figure shows, in an implementation that includes EL2, if the translation is stage 1 of the Non-secure PL1&0 translation regime, then the descriptor address is in the IPA address space, and is subject to a stage 2 translation to obtain the required PA. This stage 2 translation requires a recursive entry to the fault checking sequence.

Note

[Figure G4-17 on page G4-4115](#) and [Figure G4-18 on page G4-4116](#) give an overview of the fault checking performed by the MMU. See [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#) for the complete set of possible faults and their prioritization.

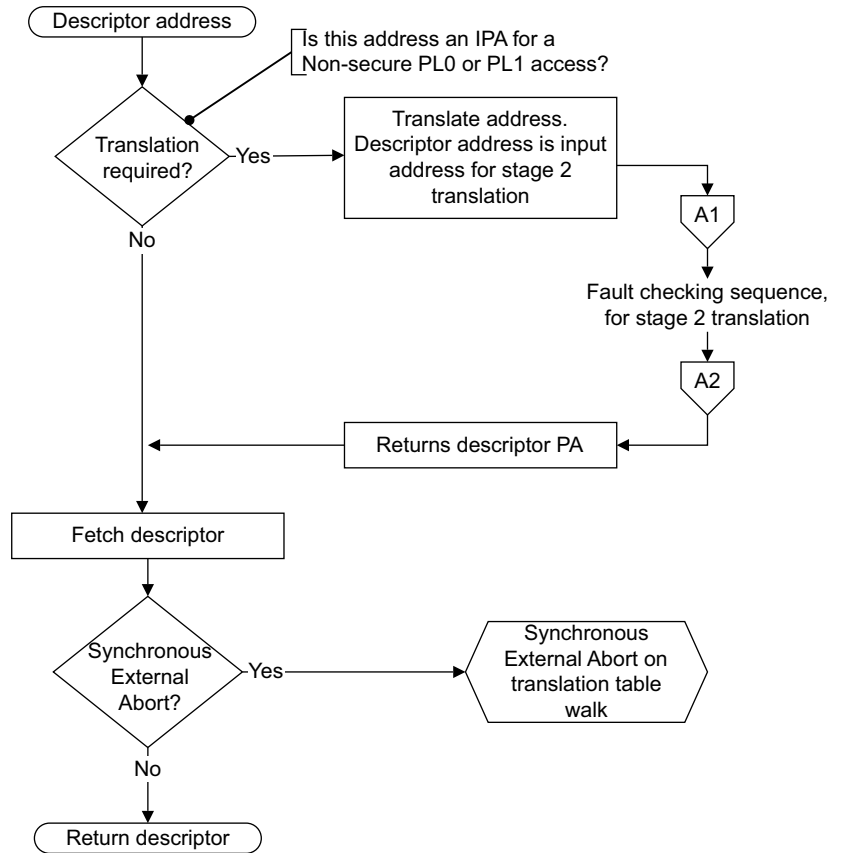

Figure G4-17 Fetching the descriptor in a VMSAv8-32 translation table walk

Figure G4-18 shows the full VMSAv8-32 fault checking sequence, including the alignment check on the initial access.

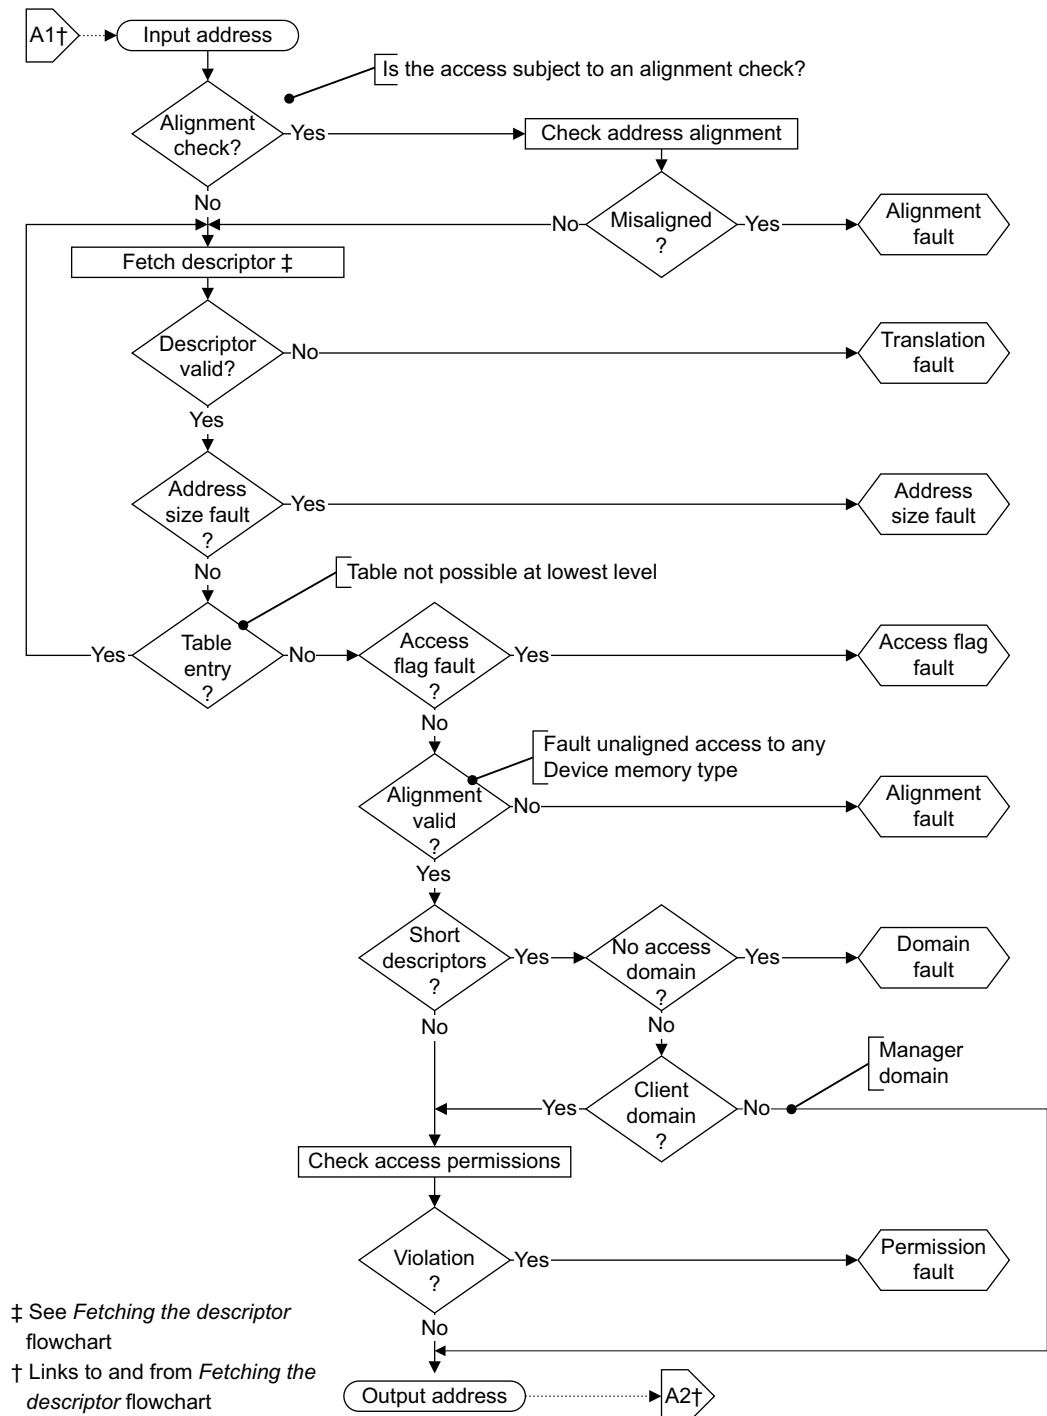

Figure G4-18 VMSAv8-32 fault checking sequence

Stage 2 fault on a stage 1 translation table walk

When an implementation that includes EL2 is operating in a Non-secure PL1 or PL0 mode, any memory access goes through two stages of translation:

- Stage 1, from VA to IPA.
- Stage 2, from IPA to PA.

———— Note ————

In a virtualized system that is using AArch32, typically, a Guest OS operating in a Non-secure PL1 mode defines the translation tables and translation table register entries controlling the Non-secure PL1&0 stage 1 translations. A Guest OS has no awareness of the stage 2 address translation, and therefore believes it is specifying translation table addresses in the physical address space. However, it actually specifies these addresses in its IPA space. Therefore, to support virtualization, translation table addresses for the Non-secure PL1&0 stage 1 translations are always defined in the IPA address space.

On performing a translation table walk for the stage 1 translations, the descriptor addresses must be translated from IPA to PA, using a stage 2 translation. This means that a memory access made as part of a stage 1 translation table lookup might generate, on a stage 2 translation:

- A Translation fault, Access flag fault, or Permission fault.
- A synchronous external abort on the memory access.

If **SCR.EA** is set to 1, a synchronous external abort is taken to EL3, and if EL3 is using AArch32 it is taken to Secure Monitor mode. Otherwise, these faults are reported as stage 2 memory aborts. When EL2 is using AArch32, **HSR.ISS[7]** is set to 1, to indicate a stage 2 fault during a stage 1 translation table walk, and the part of the ISS field that might contain details of the instruction is invalid. For more information see [Use of the HSR on page G4-4137](#).

Alternatively, a memory access made as part of a stage 1 translation table lookup might target an area of memory with the any type of Device memory attribute assigned on the stage 2 translation of the address accessed. When the value of the **HCR.PTW** bit is 1, such an access generates a stage 2 Permission fault.

———— Note ————

- On most systems, such a mapping to a Device memory type on the stage 2 translation is likely to indicate a Guest OS error, where the stage 1 translation table is corrupted. Therefore, it is appropriate to trap this access to the hypervisor.

A TLB might hold entries that depend on the effect of **HCR.PTW**. Therefore, if **HCR.PTW** is changed without changing the current VMID, the TLBs must be invalidated before executing in a Non-secure PL1 or PL0 mode. For more information see [Changing HCR.PTW on page G4-4098](#).

A cache maintenance instruction performed from a Non-secure PL1 mode can cause a stage 1 translation table walk that might generate a stage 2 Permission fault, as described in this section. This is an exception to the general rule that a cache maintenance instruction cannot generate a Permission fault.

G4.11.4 Alignment faults

The ARM memory architecture requires support for strict alignment checking. This checking is controlled by **SCTLR.A**. In addition, some instructions do not support unaligned accesses, regardless of the value of **SCTLR.A**. [Unaligned data access on page E2-2323](#) defines when Alignment faults are generated, for both values of **SCTLR.A**.

An Alignment fault can occur on an access for which the stage of address translation is disabled.

Any unaligned access to memory region with any Device memory type attribute generates an Alignment fault.

[Routing of aborts taken to AArch32 state on page G4-4110](#) defines the mode to which an Alignment fault is taken.

The prioritization of Alignment faults depends on whether the fault was generated because of an access to a Device memory type, or for another reason. For more information see [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#).

G4.11.5 MMU faults in AArch32 state

This section describes the faults that might be detected during one of the fault-checking sequences described in *The MMU fault-checking sequence* on page G4-4113. Unless indicated otherwise, information in this section applies to the fault checking sequences for both the Short-descriptor translation table format and the Long-descriptor translation table format.

MMU faults are always synchronous.

When an MMU fault generates an abort for a region of memory, no memory access is made if that region is or could be marked as any type of Device memory.

The following subsections describe the MMU faults that might be detected during a fault checking sequence:

- *Permission fault.*
- *Translation fault* on page G4-4119.
- *Address size fault* on page G4-4119.
- *Access flag fault* on page G4-4119.
- *Domain fault, Short-descriptor format translation tables* only on page G4-4120.
- *TLB conflict aborts* on page G4-4091.

See also *External abort on a translation table walk* on page G4-4120.

Note

- Although the TLB conflict abort is classified as an MMU fault, it is described in the section *Translation Lookaside Buffers (TLBs)* on page G4-4089.
- In VMSAv8-64 an external abort on a translation table walk is classified as an MMU fault. However, in VMSAv8-32, for consistency with earlier versions of the architecture these aborts are not classified as MMU faults.

Permission fault

A Permission fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. See *Access permissions* on page G4-4068 for information about conditions that cause a Permission fault.

Note

When using the Short-descriptor translation table format, the translation table descriptors are checked for Permission faults only for accesses to memory regions in Client domains.

A TLB might hold a translation table entry that cause a Permission fault. Therefore, if the handling of a Permission fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in *Ordering and completion of TLB maintenance instructions* on page G4-4096.

Note

In an implementation that includes EL2, this maintenance requirement applies to Permission faults in both stage 1 and stage 2 translations.

Cache or branch predictor maintenance operations cannot cause a Permission fault, except that:

- A stage 1 translation table walk performed as part of a cache or branch predictor maintenance operation can generate a stage 2 Permission fault as described in *Stage 2 fault on a stage 1 translation table walk* on page G4-4117.
- A DCIMVAC issued in Non-secure state that attempts to update a location for which it does not have stage 2 write access can generate a stage 2 Permission fault, as described in *AArch32 data cache maintenance instructions (DC*)* on page G3-4001.

Translation fault

A Translation fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. A Translation fault is generated if bits[1:0] of a translation table descriptor identify the descriptor as either a Fault encoding or a reserved encoding. For more information see:

- [VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4041](#).
- [VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4050](#).

In addition, a Translation fault is generated if the input address for a translation either does not map onto an address range of a **TTBR**, or the **TTBR** range that it maps onto is disabled. In these cases the fault is reported as a level 1 Translation fault on the translation stage at which the mapping to a region described by a **TTBR** failed.

The architecture guarantees that any translation table entry that causes a Translation fault is not cached, meaning the TLB never holds such an entry. Therefore, when a Translation fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

A data or unified cache maintenance instruction by VA can generate a Translation fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate a Translation fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate a Translation fault.

Address size fault

An Address size fault can be generated at any level of lookup, and the reported fault code identifies the lookup level.

An Address size fault is generated if the translation table entries or the **TTBR** for the stage of translation have nonzero address bits above the most significant bit of the maximum output address size. Because VMSAv8-32 supports a maximum PA and IPA size of 40 bits, this means any case where a translation table entry or the **TTBR** holds an address for which A[47:40] is nonzero generates an Address size fault.

A data or unified cache maintenance instruction by VA can generate an Address size fault. It is IMPLEMENTATION DEFINED whether an instruction cache invalidate by VA operation can generate an Address size fault.

It is IMPLEMENTATION DEFINED whether a branch predictor maintenance operation can generate an Address size fault.

The architecture guarantees that any translation table entry that causes an Address size fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Address size fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Access flag fault

An Access flag fault can be generated at any level of lookup, and the reported fault code identifies the lookup level. An Access flag fault is generated only if all of the following apply:

- The translation tables support an Access flag bit:
 - The Short-descriptor format supports an Access flag only when **SCTLR.AFE** is set to 1.
 - The Long-descriptor format always supports an Access flag.
- A translation table descriptor with the Access flag bit set to 0 is loaded.

For more information about the Access flag bit see:

- [VMSAv8-32 Short-descriptor translation table format descriptors on page G4-4041](#)
- [VMSAv8-32 Long-descriptor translation table format descriptors on page G4-4050](#).

The architecture guarantees that any translation table entry that causes an Access flag fault is not cached, meaning the TLB never holds such an entry. Therefore, when an Access flag fault occurs, the fault handler does not have to perform any TLB maintenance instructions to remove the faulting entry.

Whether any cache maintenance instruction by VA can generate Access flag faults is IMPLEMENTATION DEFINED.

Whether branch predictor invalidate by VA operations can generate Access flag faults is IMPLEMENTATION DEFINED.

For more information, see [The Access flag on page G4-4074](#).

Domain fault, Short-descriptor format translation tables only

When using the Short-descriptor translation table format, a Domain fault can be generated at level 1 or level 2 of lookup. The reported fault code identifies the lookup level. The conditions for generating a Domain fault are:

- Level 1** When a level 1 descriptor fetch returns a valid Section level 1 descriptor, the domain field of that descriptor is checked against the [DACR](#). A level 1 Domain fault is generated if this check fails.
- Level 2** When a level 2 descriptor fetch returns a valid level 2 descriptor, the domain field of the level 1 descriptor that required the level 2 fetch is checked against the [DACR](#), and a level 2 Domain fault is generated if this check fails.

For more information, see [Domains, Short-descriptor format only](#) on page G4-4073.

Domain faults cannot occur on cache or branch predictor maintenance operations.

A TLB might hold a translation table entry that cause a Domain fault. Therefore, if the handling of a Domain fault results in an update to the associated translation tables, the software that updates the translation tables must invalidate the appropriate TLB entry, to prevent the stale information in the TLB being used on a subsequent memory access. For more information, see the translation table entry update examples in [Ordering and completion of TLB maintenance instructions](#) on page G4-4096.

Any change to the [DACR](#) must be synchronized by a [Context synchronization event](#). For more information see [Synchronization of changes to AArch32 System registers](#) on page G4-4163.

G4.11.6 External abort on a translation table walk

An external abort on a translation table walk can be either synchronous or asynchronous. For more information on external aborts, see [External aborts](#) on page G3-4014.

An external abort on a translation table walk is reported:

- If the external abort is synchronous, using:
 - A synchronous Prefetch Abort exception if the translation table walk is for an instruction fetch.
 - A synchronous Data Abort exception if the translation table walk is for a data access.
- If the external abort is asynchronous, using an SError interrupt, which is taken as an asynchronous Data Abort exception.

If an implementation reports the error in the translation table walk asynchronously from executing the instruction whose instruction fetch or memory access caused the translation table walk, these aborts behave essentially as interrupts. The aborts are masked when [PSTATE.A](#) is set to 1, otherwise they are reported using the Data Abort exception.

Behavior of external aborts on a translation table walk caused by address translation instructions

The address translation instructions summarized in [Address translation instructions, functional group](#) on page G4-4204 require translation table walks. An external abort can occur in the translation table walk. The abort generates a Data Abort exception, and can be synchronous or asynchronous. For more information, see [Handling of faults and aborts during an address translation instruction](#) on page G4-4146.

G4.11.7 AArch32 state prioritization of synchronous aborts from a single stage of address translation

[Exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 describes the prioritization of exceptions taken from an Exception level that is using AArch32. This section gives additional information about the prioritization of MMU faults from VMSAv8-32 translation regimes.

If a single instruction generates aborts on more than one memory access, the architecture does not define any prioritization between those aborts.

In general, the ARM architecture does not define when asynchronous events are taken, and therefore the prioritization of asynchronous events is IMPLEMENTATION DEFINED.

———— **Note** ————

The priority numbering in this list only shows the relative priorities of aborts from a single stage of address translation in a VMSAv8-32 translation regime. This numbering has no global significance and, for example, does not correlate with the equivalent AArch64 list in *AArch64 state prioritization of synchronous aborts from a single stage of address translation* on page D4-1807.

For a single stage of translation in a VMSAv8-32 translation regime, the following numbered list shows the priority of the possible memory management faults on a memory access. In this list:

- For memory accesses that undergo two stages of translation, the *italic entries show where the faults from the stage 2 translation can occur*. A stage 2 fault within a stage 1 translation table walk follows the same prioritization of faults.
- For synchronous external aborts from translation table walks see also *Synchronous external abort errors from address translation caching structures* on page G4-4122.

The priority order, from highest priority to lowest priority, is:

1. Alignment fault not caused by memory type. This is possible for a stage 1 translation only.
2. Translation fault due to the input address being out of the address range to be translated or requiring an AArch32 **TTBR** that is disabled. This includes **VTCR.SL0** being inconsistent with **VTCR.TOSZ** or programmed to a reserved value.
3. Address size fault on an AArch32 **TTBR** caused by the physical address being out of the range implemented.
4. *Second stage abort on a level 1 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.*
5. Synchronous parity or ECC error on a level 1 lookup of a translation table walk.
6. Synchronous external abort on a level 1 lookup level of a translation table walk.
7. Translation fault on a level 1 translation table entry.
8. Address size fault on a level 1 lookup translation table entry caused by the output address being out of the range implemented.
9. *Second stage abort on a level 2 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.*
10. Synchronous parity or ECC error on a level 2 lookup of a translation table walk.
11. Synchronous external abort on a level 2 lookup level of a translation table walk.
12. Translation fault on a level 2 translation table entry.
13. Address size fault on a level 2 lookup translation table entry caused by the output address being out of the range implemented.
14. *Second stage abort on a level 3 lookup of a stage 1 table walk. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented. This is second stage abort during a first stage translation table walk.*
15. Synchronous parity or ECC error on a level 3 lookup of a translation table walk.
16. Synchronous external abort on a level 3 lookup level of a translation table walk.
17. Translation fault on a level 3 translation table entry.
18. Address size fault on a level 3 lookup translation table entry caused by the output address being out of the range implemented.

19. Access Flag fault.
20. Alignment fault caused by the memory type.
21. Domain fault.

———— **Note** —————

Domain faults are possible only when using the VMSAv8-32 Short-descriptor translation table format, see [Domain fault, Short-descriptor format translation tables only on page G4-4120](#).

22. Permission fault.
23. *A fault from the stage 2 translation of the memory access. When stage 2 address translation is enabled this includes an Address size fault caused by the physical address being out of the range implemented.*
24. Synchronous parity or ECC error on the memory access.
25. Synchronous External Abort on the memory access.

———— **Note** —————

- The prioritization of TLB Conflict aborts is IMPLEMENTATION DEFINED, as the exact cause of these aborts depends on the form of TLBs implemented. However, the TLB conflict abort must have higher priority than any abort that depends on a value held in the TLB.
- The prioritization of IMPLEMENTATION DEFINED MMU faults for a Load-Exclusive or Store-Exclusive to an unsupported memory type is IMPLEMENTATION DEFINED.

See also [The MMU fault-checking sequence on page G4-4113](#).

Synchronous external abort errors from address translation caching structures

A caching structure used for caching translation table walks might support:

- An arbitrary number of levels of translation table lookup.
- One or more stages of translation, that might not correspond to the stages of an address translation lookup.

This might mean that, on a synchronous external abort arising from the caching structure, such as from a parity or ECC error, the PE cannot precisely determine one or both of the translation stage and level of lookup at which the error occurred. In this case:

- If the PE cannot determine precisely the translation stage at which the error occurred, it is reported and prioritized as a stage 1 error.
- If the PE cannot determine precisely the lookup level at which the error occurred, the level is reported and prioritized as either:
 - The lowest-numbered level that could have given rise to the error.
 - Level 1 if the PE cannot determine any information about the level.

G4.12 Exception reporting in a VMSAv8-32 implementation

This section describes exception reporting, in AArch32 state, in a VMSAv8-32 implementation. That is, it describes only the reporting of exceptions that are taken to an Exception level that is using AArch32. EL2 provides an enhanced reporting mechanism for exceptions taken to the Non-secure EL2 mode, Hyp mode. This means that, for VMSAv8-32, the exception reporting depends on the mode to which the exception is taken.

Note

The enhanced reporting mechanism for exceptions that are taken to Hyp mode is generally similar to the reporting of exceptions that are taken to an Exception level that is using AArch64.

About exception reporting introduces the general approach to exception reporting, and the following sections then describe exception reporting at different privilege levels:

- *Reporting exceptions taken to PL1 modes on page G4-4124.*
- *Fault reporting in PL1 modes on page G4-4127.*
- *Summary of register updates on faults taken to PL1 modes on page G4-4131.*
- *Reporting exceptions taken to Hyp mode on page G4-4133.*
- *Use of the HSR on page G4-4137.*
- *Summary of register updates on exceptions taken to Hyp mode on page G4-4140.*

Note

The registers used for exception reporting also report information about debug exceptions. For more information see:

- *Data Abort exceptions, taken to a PL1 mode on page G4-4125.*
 - *Prefetch Abort exceptions, taken to a PL1 mode on page G4-4127.*
 - *Reporting exceptions taken to Hyp mode on page G4-4133.*
-

G4.12.1 About exception reporting

In an implementation that includes EL2 and EL3, exceptions can be taken to:

- Monitor mode, if EL3 is using AArch32.
- Hyp mode, if EL2 is using AArch32.
- A Secure or Non-secure PL1 mode.

Monitor mode is a PL1 mode, but:

- It is accessible only when EL3 is using AArch32.
- It is present only in Secure state.
- When EL3 is using AArch32, System register controls route some exceptions from Non-secure state to Monitor mode. These are the only cases where taking an exception to an Exception level that is using AArch32 changes the Security state of the PE.

Exception reporting in Hyp mode differs significantly from that in the other modes, but in general, exception reporting returns:

- Information about the exception:
 - On taking an exception to Hyp mode, the *Hyp Syndrome Register*, **HSR**, returns syndrome information.
 - On taking an exception to any other mode, a *Fault Status Register* (FSR) returns status information.
- For synchronous exceptions, one or more addresses associated with the exceptions, returned in *Fault Address Registers* (FARs). For a permitted exception to this requirement see *Fault address reporting on synchronous external aborts on page G4-4124*.

In all modes, additional IMPLEMENTATION DEFINED registers can provide additional information about exceptions.

Note

- [PE mode for taking exceptions on page G1-3822](#) describes how the mode to which an exception is taken is determined.
 - EL2 provides:
 - Specific exception types, that can only be taken from Non-secure PL1 and PL0 modes, and are always taken to Hyp mode.
 - Routing controls that can route some exceptions from Non-secure PL1 and PL0 modes to Hyp mode. These exceptions are reported using the same mechanism as the Hyp mode reporting of VMSAv8-32 memory aborts, as described in this section.
-

Memory system faults generate either a Data Abort exception or a Prefetch Abort exception, as summarized in:

- [Reporting exceptions taken to PL1 modes.](#)
- [Memory fault reporting in Hyp mode on page G4-4135.](#)

On an access that might have multiple aborts, the MMU fault checking sequence and the prioritization of aborts determine which abort occurs. For more information, see [The MMU fault-checking sequence on page G4-4113](#) and [AArch32 state prioritization of synchronous aborts from a single stage of address translation on page G4-4120](#).

Fault address reporting on synchronous external aborts

The general architectural requirement is that, on a synchronous abort, the faulting address is recorded in a *Fault Address Register* (FAR). This requirement is relaxed for the case of a synchronous external abort that is not a synchronous external abort on a translation table walk. In this case only:

- It is IMPLEMENTATION DEFINED whether the faulting address is recorded in a FAR.
- A bit in a fault reporting register, the FnV bit, indicates whether a valid address is recorded.

For exceptions taken to an Exception level that is using AArch32, the details of this reporting depend on whether the exception is taken to:

- A PL1 mode, as described in [Reporting exceptions taken to PL1 modes.](#)
- Hyp mode, as described in [Reporting exceptions taken to Hyp mode on page G4-4133.](#)

G4.12.2 Reporting exceptions taken to PL1 modes

The following sections give general information about the reporting of exceptions when they are taken to a Secure or Non-secure PL1 mode:

- [Registers used for reporting exceptions taken to PL1 modes on page G4-4125.](#)
- [Data Abort exceptions, taken to a PL1 mode on page G4-4125.](#)
- [Prefetch Abort exceptions, taken to a PL1 mode on page G4-4127.](#)

[Fault reporting in PL1 modes on page G4-4127](#) then describes the fault reporting in these modes, including the encodings used for reporting the faults.

Note

[Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#) describes how the Secure and Non-secure PL1 modes map onto the Exception levels.

Registers used for reporting exceptions taken to PL1 modes

AArch32 state defines the following registers, and register encodings, for exceptions taken to PL1 modes:

- The **DFSR** holds information about a Data Abort exception.
- The **DFAR** holds the faulting address for some synchronous Data Abort exceptions.
- The **IFSR** holds information about a Prefetch Abort exception.
- The **IFAR** holds the faulting address for some synchronous Prefetch Abort exceptions.

In addition, if implemented, the optional ADFSR and AIFSR can provide additional fault information, see [Auxiliary Fault Status Registers](#).

Auxiliary Fault Status Registers

AArch32 state defines the following Auxiliary Fault Status Registers:

- The Auxiliary Data Fault Status Register, **ADFSR**.
- The Auxiliary Instruction Fault Status Register, **AIFSR**.

The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED. An implementation can use these registers to return additional fault status information. An example use of these registers is to return more information for diagnosing parity or ECC errors.

An implementation that does not need to report additional fault information must implement these registers as UNK/SBZP. This ensures that an attempt to access these registers from software executing at PL1 does not cause an Undefined Instruction exception.

Data Abort exceptions, taken to a PL1 mode

On taking a Data Abort exception to a PL1 mode:

- If the exception is on an instruction cache or branch predictor maintenance operation by VA, its reporting depends on the value of **TTBCR.EAE**. For more information about the registers used when reporting the exception, see [Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4126](#).
- Otherwise, the **DFSR** is updated with details of the fault, including the appropriate fault status code. If the Data Abort exception is synchronous, **DFSR.WnR** is updated to indicate whether the faulted instruction was a read or a write. However, if the fault is on a cache maintenance instruction, or on an address translation instruction, **WnR** is set to 1, to indicate a fault on a write instruction, and the **CM** bit is set to 1.

See the register description for more information about the returned fault information. See also [Data Abort on a Watchpoint exception on page G4-4126](#).

If the Data Abort exception is

- Synchronous, the **DFAR** is updated with the VA that caused the exception, but see [Fault address reporting on synchronous external aborts on page G4-4124](#) for a permitted exception to this requirement.
- Asynchronous, the **DFAR** becomes UNKNOWN.

DFSR.WnR and **DFSR.CM** are UNKNOWN on an asynchronous Data Abort exception.

For all Data Abort exceptions, if the implementation includes EL3, the Security state of the PE in the mode to which the Data Abort exception is taken determines whether the Secure or Non-secure **DFSR** and **DFAR** are updated.

Data Abort on an instruction cache or branch predictor maintenance instruction by VA

If an instruction cache invalidation by VA or branch predictor invalidation by VA operation generates a Data Abort exception that is taken to a PL1 mode, the **DFAR** is updated to hold the faulting VA. However, the reporting of the fault depends on the value of **TTBCR.EAE**:

TTBCR.EAE == 0

When the value of **TTBCR.EAE** is 0, it is IMPLEMENTATION DEFINED which of the following is used when reporting the fault:

- The **DFSR** indicates an Instruction cache maintenance instruction fault, and the **IFSR** is valid and indicates the cause of the fault, a Translation fault or Access flag fault.
- The **DFSR** indicates the cause of the fault, a Translation fault or Access flag fault. The **IFSR** is UNKNOWN.

In either case:

- **DFSR.WnR** is set to 1.
- **DFSR.CM** is set to 1, to indicate a fault on a cache maintenance instruction.

TTBCR.EAE == 1

When the value of **TTBCR.EAE** is 1:

- **DFSR.CM** is set to 1, to indicate a fault on a cache maintenance instruction.
- **DFSR.STATUS** indicates the cause of the fault, a Translation or Access flag fault.
- **DFSR.WnR** is set to 1.
- The **IFSR** is UNKNOWN.

Data Abort on a Watchpoint exception

On taking a Data Abort exception caused by a watchpoint:

- **DFSR.FS** is updated to indicate a debug exception.
- **DFSR**.{WnR, Domain} are UNKNOWN.
- **DFAR** is set to the address that generated the watchpoint

Note

- **LR_abt** indicates the address of the instruction that triggered the watchpoint.
- In some ARMv7 AArch32 implementations, the **DBGWFAR** is set to the address of the instruction that triggered the watchpoint. In ARMv8 this register is **RES0**.

A watchpointed address can be any byte-aligned address. The address reported in **DFAR** might not be the watchpointed address, and:

- For a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:
 - The lowest address accessed by the instruction that triggered the watchpoint.
 - The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

- In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.
- The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 **DC ZVA** operation.

- For a watchpoint due to a Data Cache operation, the address is the address passed to the instruction. This might be an address that is above the watchpointed location.

Prefetch Abort exceptions, taken to a PL1 mode

For a Prefetch Abort exception generated by an instruction fetch, the Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction, no Prefetch Abort exception is generated.

In addition, Breakpoint Instruction, Breakpoint, and Vector Catch exceptions, generate a Prefetch Abort exception, see the following for more information:

- [Exception syndrome information and preferred return address on page G2-3936](#) for Breakpoint Instruction exceptions.
- [Exception syndrome information and preferred return address on page G2-3958](#) for Breakpoint exceptions.
- [Exception syndrome information and preferred return address on page G2-3980](#) for Vector Catch exceptions.

On taking a Prefetch Abort exception to a PL1 mode:

- The **IFSR** is updated with details of the fault, including the appropriate fault code. If appropriate, the fault code indicates that the exception was generated by a debug exception.
See the register description for more information about the returned fault information.
- For a Prefetch Abort exception generated by an instruction fetch, the **IFAR** is updated with the VA that caused the exception, but see [Fault address reporting on synchronous external aborts on page G4-4124](#) for a permitted exception to this requirement.
- For a Prefetch Abort exception generated by a debug exception, the **IFAR** is UNKNOWN.

If the implementation includes EL3, the security state of the PE in the mode to which it takes the Prefetch Abort exception determines whether the exception updates the Secure or Non-secure **IFSR** and **IFAR**.

G4.12.3 Fault reporting in PL1 modes

The FSRs provide fault information, including an indication of the fault that occurred. The following subsections describe fault reporting in PL1 modes for each of the translation table formats:

- [PL1 fault reporting with the Short-descriptor translation table format on page G4-4128](#).
- [PL1 fault reporting with the Long-descriptor translation table format on page G4-4129](#).

[Reserved encoding in the IFSR and DFSR encodings tables on page G4-4131](#) gives some additional information about the encodings for both formats.

[Summary of register updates on faults taken to PL1 modes on page G4-4131](#) shows which registers are updated on each of the reported faults.

[Reporting of External aborts taken from Non-secure state to Monitor mode](#) describes how the fault status register format is determined for those aborts. For all other aborts, the current translation table format determines the format of the fault status registers.

Reporting of External aborts taken from Non-secure state to Monitor mode

When an External abort is taken from Non-secure state to Monitor mode:

- For a Data Abort exception, the Secure **DFSR** and **DFAR** hold information about the abort.
- For a Prefetch Abort exception, the Secure **IFSR** and **IFAR** hold information about the abort.
- The abort does not affect the contents of the Non-secure copies of the fault reporting registers.

Normally, the current translation table format determines the format of the **DFSR** and **IFSR**. However, when **SCR.EA** is set to 1, to route external aborts to Monitor mode, and an external abort is taken from Non-secure state, this section defines the **DFSR** and **IFSR** format.

For an External abort taken from Non-secure state to Monitor mode, the **DFSR** or **IFSR** uses the format associated with the Long-descriptor translation table format, as described in *PL1 fault reporting with the Long-descriptor translation table format on page G4-4129*, if any of the following applies:

- The Secure **TTBCR.EAE** bit is set to 1.
- The External abort is synchronous and either:
 - It is taken from Hyp mode.
 - It is taken from a Non-secure PL1 or PL0 mode, and the Non-secure **TTBCR.EAE** bit is set to 1.

Otherwise, the **DFSR** or **IFSR** uses the format associated with the Short-descriptor translation table format, as described in *PL1 fault reporting with the Short-descriptor translation table format*.

PL1 fault reporting with the Short-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 when address translation is using the Short-descriptor translation table format.

On taking an exception, bit[9] of the FSR is RAZ, or set to 0, if the PE is using this FSR format.

An FSR encodes the fault in a 5-bit FS field, that comprises FSR[10, 3:0]. [Table G4-24](#) shows the encoding of that field. *Summary of register updates on faults taken to PL1 modes on page G4-4131* shows:

- Whether the corresponding FAR is updated on the fault. That is:
 - For a fault reported in the **IFSR**, whether the **IFAR** holds a valid address.
 - For a fault reported in the **DFSR**, whether the **DFAR** holds a valid address.
- For faults that update **DFSR**, whether **DFSR.Domain** is valid

When reading [Table G4-24](#):

- FS values not shown in the table are reserved.
- FS values shown as **DFSR** only are reserved for the **IFSR**.

Table G4-24 FSR encodings when using the Short-description translation table format

| FS | Source | | Notes |
|-------|--|---------|---|
| 00001 | Alignment fault | | DFSR only. Fault on initial lookup |
| 00100 | Fault on instruction cache maintenance | | DFSR only |
| 01100 | Synchronous external abort on translation table walk ^a | Level 1 | - |
| 01110 | | Level 2 | |
| 11100 | Synchronous parity or ECC error on translation table walk ^a | Level 1 | - |
| 11110 | | Level 2 | |
| 00101 | Translation fault ^a | Level 1 | MMU fault |
| 00111 | | Level 2 | |
| 00011 | Access flag fault ^a | Level 1 | MMU fault |
| 00110 | | Level 2 | |
| 01001 | Domain fault ^a | Level 1 | MMU fault |
| 01011 | | Level 2 | |

Table G4-24 FSR encodings when using the Short-description translation table format (continued)

| FS | Source | Notes |
|-------|---|--|
| 01101 | Permission fault ^a | Level 1 |
| 01111 | | Level 2 |
| 00010 | Debug exception | See Chapter G2 AArch32 Self-hosted Debug |
| 01000 | Synchronous external abort | - |
| 10000 | TLB conflict abort | See TLB conflict aborts on page G4-4091 |
| 10100 | IMPLEMENTATION DEFINED | Lockdown |
| 10101 | IMPLEMENTATION DEFINED | Unsupported Exclusive access |
| 11001 | Synchronous parity or ECC error on memory access | - |
| 10110 | SError interrupt ^c | DFSR only |
| 11000 | SError interrupt ^c from a parity or ECC error on memory access | DFSR only |

- See [The level associated with MMU faults on a Short-descriptor translation table lookup](#).
- Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use
- Including asynchronous external abort on a data access, a translation table walk, or an instruction fetch.

The level associated with MMU faults on a Short-descriptor translation table lookup

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, Permission fault, or Domain fault, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Supersection, Section, or Page descriptor.

Also see [Synchronous external abort errors from address translation caching structures on page G4-4122](#).

The Domain field in the DFSR

The DFSR includes a Domain field. This is inherited from previous versions of the VMSA. The IFSR does not include a Domain field. [Summary of register updates on faults taken to PL1 modes on page G4-4131](#) describes when DFSR.Domain is valid.

ARM deprecates any use of the Domain field in the DFSR. The Long-descriptor translation table format does not support a Domain field, and future versions of the ARM architecture might not support a Domain field in the Short-descriptor translation table format. ARM strongly recommends that new software does not use this field.

For both Data Abort exceptions and Prefetch Abort exceptions, software can find the domain information by performing a translation table read for the faulting address and extracting the Domain field from the translation table entry.

PL1 fault reporting with the Long-descriptor translation table format

This subsection describes the fault reporting for a fault taken to a PL1 mode when address translation is using the Long-descriptor translation table format.

When the PE takes an exception, bit[9] of the FSR is set to 1 if the PE is using this FSR format.

The FSRs encode the fault in a 6-bit STATUS field, that comprises FSR[5:0]. [Table G4-25](#) shows the encoding of that field. In addition:

- For a fault taken to a PL1 mode, [Summary of register updates on faults taken to PL1 modes on page G4-4131](#) shows whether the corresponding FAR is updated on the fault. That is:
 - For a fault reported in the **IFSR**, whether the **IFAR** holds a valid address.
 - For a fault reported in the **DFSR**, whether the **DFAR** holds a valid address.
- For a fault taken to the Hyp mode, [Summary of register updates on exceptions taken to Hyp mode on page G4-4140](#) shows what registers are updated on the fault.

Table G4-25 FSR encodings when using the Long-descriptor translation table format

| STATUS ^a | Source | Notes |
|---------------------|--|--|
| 0000LL | Address size fault. LL bits indicate level ^b . | MMU fault |
| 0001LL | Translation fault. LL bits indicate level ^b . | MMU fault |
| 0010LL | Access flag fault. LL bits indicate level ^b . | MMU fault |
| 0011LL | Permission fault. LL bits indicate level ^b . | MMU fault |
| 010000 | Synchronous external abort. | - |
| 011000 | Synchronous parity or ECC error on memory access. | - |
| 010001 | SError interrupt ^c . | DFSR only |
| 011001 | SError interrupt ^c from a parity or ECC error on memory access. | DFSR only |
| 0101LL | Synchronous external abort on translation table walk. LL bits indicate level ^b . | - |
| 0111LL | Synchronous parity or ECC error on memory access on translation table walk. LL bits indicate level ^b . | - |
| 100001 | Alignment fault. | Fault on initial lookup |
| 100010 | Debug exception. | See Chapter G2 AArch32 Self-hosted Debug |
| 110000 | TLB conflict abort. | See TLB conflict aborts on page G4-4091 |
| 110100 | IMPLEMENTATION DEFINED. | Lockdown, DFSR only |
| 110101 | IMPLEMENTATION DEFINED. | Unsupported Exclusive access |
| 1111LL | Domain fault. LL bits indicate level ^b . | MMU fault. 64-bit PAR only, level 1 or level 2 only. Never used in DFSR , IFSR , or HSR ^d |

- a. STATUS values not shown in this table are reserved. STATUS values not supported in the **IFSR** or **DFSR** are reserved for the register or registers in which they are not supported.
- b. See [The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4131](#).
- c. Including asynchronous external abort on a data access, a translation table walk, or an instruction fetch.
- d. A Domain fault can be reported using the Long-descriptor STATUS encodings only as a result of a fault on an address translation instruction. For more information see [MMU fault on an address translation instruction on page G4-4146](#).

The level associated with MMU faults on a Long-descriptor translation table lookup

For MMU faults, [Table G4-26](#) shows how the LL bits in the xFSR.STATUS field encode the lookup level associated with the fault.

Table G4-26 Use of LL bits to encode the lookup level at which the fault occurred

| LL bits | Meaning |
|---------|---|
| 00 | Address size fault Address size fault in TTBR0 or TTBR1 . All other faults Reserved. |
| 01 | Level 1. |
| 10 | Level 2. |
| 11 | Level 3. When xFSR.STATUS indicates a Domain fault, this value is reserved. |

The lookup level associated with a fault is:

- For a fault generated on a translation table walk, the lookup level of the walk being performed.
- For a Translation fault, the lookup level of the translation table that gave the fault. If a fault occurs because a stage of address translation is disabled, or because the input address is outside the range specified by the appropriate base address register or registers, the fault is reported as a level 1 fault.
- For an Access flag fault, the lookup level of the translation table that gave the fault.
- For a Permission fault, including a Permission fault caused by hierarchical permissions, the lookup level of the final level of translation table accessed for the translation. That is, the lookup level of the translation table that returned a Block or Page descriptor.

Also see [Synchronous external abort errors from address translation caching structures](#) on page G4-4122.

Reserved encoding in the IFSR and DFSR encodings tables

With both the Short-descriptor and the Long-descriptor FSR format, the fault encodings reserve a single encoding for Cache and TLB lockdown faults. The details of these faults and any associated subsidiary registers are IMPLEMENTATION DEFINED.

G4.12.4 Summary of register updates on faults taken to PL1 modes

For faults that generate exceptions that are taken to a PL1 mode, [Table G4-27](#) on page G4-4132 shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

For faults that update the **DFSR** using the Short-descriptor format FSR encodings, [Table G4-28 on page G4-4133](#) shows whether **DFSR.Domain** is valid.

Table G4-27 Effect of a fault taken to a PL1 mode on the reporting registers

| Fault | | IFSR | IFAR | DFSR | DFAR |
|---|---------------|-------------|----------------------|-------------|----------------------|
| Faults reported as Prefetch Abort exceptions: | | | | | |
| MMU fault, always synchronous | | Yes | Yes | - | - |
| Synchronous external abort on translation table walk | | Yes | Yes | - | - |
| Synchronous parity or ECC error on translation table walk | | Yes | Yes | - | - |
| Synchronous external abort | | Yes | IMP DEF ^a | - | - |
| Synchronous parity or ECC error on memory access | | Yes | Yes | - | - |
| TLB conflict abort | | Yes | Yes | - | - |
| Fault reported as Data Abort exception: | | | | | |
| Alignment fault, always synchronous | | - | - | Yes | Yes |
| MMU fault, always synchronous | | - | - | Yes | Yes |
| Fault on instruction cache maintenance, when using Long-descriptor translation table format ^b | | UNK | - | Yes | Yes |
| Fault on instruction cache maintenance, when using Short descriptor translation table format ^c | <i>either</i> | Yes | - | Yes | Yes |
| | <i>or</i> | UNK | - | Yes | Yes |
| Synchronous external abort on translation table walk | | - | - | Yes | Yes |
| Synchronous parity or ECC error on translation table walk | | - | - | Yes | Yes |
| Synchronous external abort | | - | - | Yes | IMP DEF ^a |
| Synchronous parity or ECC error on memory access | | - | - | Yes | Yes |
| SError interrupt | | - | - | Yes | UNK |
| SError interrupt from a parity or ECC error on memory access | | - | - | Yes | UNK |
| TLB conflict abort | | - | - | Yes | Yes |
| Debug exceptions: | | | | | |
| Breakpoint, Breakpoint Instruction, or Vector Catch ^d | | Yes | UNK | - | - |
| Watchpoint ^e | | - | - | Yes | Yes |

a. IMPLEMENTATION DEFINED. The **IFSR.FnV** or **DFSR.FnV** bit indicates whether the register holds a valid address. See [Fault address reporting on synchronous external aborts on page G4-4124](#).

b. When using the Long-descriptor translation table format, there is not a specific fault code for a fault on an instruction cache maintenance instruction. For more information see [Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4126](#).

c. The two lines of this entry show the alternative ways of reporting the fault when using the Short-descriptor translation table format. It is IMPLEMENTATION DEFINED which methods is used, see [Data Abort on an instruction cache or branch predictor maintenance instruction by VA on page G4-4126](#).

d. Generates a Prefetch Abort exception.

e. Generates a Data Abort exception.

For those faults for which [Table G4-27 on page G4-4132](#) shows that the **DFSR** is updated, if the fault is reported using the Short-descriptor FSR encodings, [Table G4-28](#) shows whether **DFSR.Domain** is valid. In this table, UNK indicates that the fault makes **DFSR.Domain** UNKNOWN.

Table G4-28 Validity of Domain field on faults that update the **DFSR when using the Short-descriptor encodings**

| DFSR.FS | Source | | DFSR.Domain | Notes |
|--------------------|---|---------|--------------------|--------------|
| 00001 | Alignment fault | | UNK | - |
| 00100 | Fault on instruction cache maintenance instruction | | UNK | - |
| 01100 | Synchronous external abort on translation table walk | Level 1 | UNK | - |
| 01110 | | Level 2 | Valid | |
| 11100 | Synchronous parity or ECC error on translation table walk | Level 1 | UNK | - |
| 11110 | | Level 2 | Valid | |
| 00101 | Translation fault | Level 1 | UNK | MMU fault |
| 00111 | | Level 2 | Valid | |
| 00011 ^a | Access flag fault | Level 1 | UNK | MMU fault |
| 00110 | | Level 2 | Valid | |
| 01001 | Domain fault | Level 1 | Valid | MMU fault |
| 01011 | | Level 2 | Valid | |
| 01101 | Permission fault | Level 1 | UNK | MMU fault |
| 01111 | | Level 2 | UNK | |
| 01000 | Synchronous external abort | | UNK | - |
| 10000 | TLB conflict abort | | UNK | - |
| 11001 | Synchronous parity or ECC error on memory access | | UNK | - |
| 10110 | SError interrupt ^b | | UNK | - |
| 11000 | SError interrupt ^b from a parity or ECC error on memory access | | UNK | - |
| 00010 | Watchpoint | | UNK | |

- a. Previously, this encoding was a deprecated encoding for Alignment fault. The extensive changes in the memory model in VMSAv8-32 mean there should be no possibility of confusing the new use of this encoding with its previous use
- b. Including asynchronous external abort on a data access, a translation table walk, or an instruction fetch.

G4.12.5 Reporting exceptions taken to Hyp mode

Hyp mode is the Non-secure EL2 mode. It is entered by taking an exception to Hyp mode.

————— **Note** —————

Software executing in Monitor mode, or at EL3 when EL3 is using AArch64, can perform an exception return to Hyp mode. This means Hyp mode can be entered either by taking an exception, or by a permitted exception return.

When EL2 is using AArch32, the following exceptions are taken to Hyp mode:

- SError interrupt exceptions, IRQ exceptions, and FIQ exceptions, from Non-secure PL0 and PL1 modes, if not routed to Secure Monitor mode, and if configured by the AMO, FMO or IMO bits. For more information see [Asynchronous exception routing controls on page G1-3841](#).
- When **HCR.TGE** is set to 1, all exceptions that would be routed to Non-secure PL1 modes.

For more information, see [Routing exceptions from Non-secure EL0 to EL2 on page G1-3828](#).

- When `HDCR.TDE` is set to 1, any debug exception that would otherwise be taken to a Non-secure PL1 mode, see [Routing debug exceptions to EL2 on page G1-3833](#).
- The privilege rules for taking exceptions mean that any exception taken from Hyp mode, if not routed to EL3, must be taken to Hyp mode.
- Hypervisor Call exceptions, and Hyp Trap exceptions, are always taken to Hyp mode. These exceptions are supported only as part of EL2.

When EL2 is implemented, various operations from Non-secure PL0 and PL1 modes can be *trapped* to Hyp mode, using the Hyp Trap exception. For more information, see [EL2 configurable controls on page G1-3894](#).

These exceptions include any memory system fault that occurs:

- On a memory access from Hyp mode.
- On memory access from a Non-secure PL0 or PL1 mode:
 - On a stage 2 translation, from IPA to PA.
 - On the stage 2 translation of an address accessed in performing a stage 1 translation table walk.

[Memory fault reporting in Hyp mode on page G4-4135](#) gives more information about these faults.

The following exceptions provide *syndrome* information in the `HSR`:

- Any synchronous exception taken to Hyp mode.
- Some exceptions taken from Debug state that would be taken to Hyp mode if the PE was in Non-debug state, see [Exceptions in Debug state on page H2-4874](#).

———— **Note** —————

- In Debug state, the PE does not change mode on taking an exception.
- As [Exceptions in Debug state on page H2-4874](#) describes, some other exceptions taken from Debug state make the `HSR UNKNOWN`.

The syndrome information in the `HSR` includes the fault status code otherwise provided by the fault status register, and extends the fault reporting compared to that available for an exception taken to a PL1 mode. For more information, see [Use of the HSR on page G4-4137](#).

In addition, for a Debug exception taken to Hyp mode, `DBGDSCRint.MOE` or `DBGDTRRExt.MOE` shows what caused the Debug exception. This bit is valid regardless of whether the Debug exception was taken from Hyp mode or from another Non-secure mode.

[Registers used for reporting exceptions taken to Hyp mode](#) lists all of the registers used for exception reporting in Hyp mode.

Registers used for reporting exceptions taken to Hyp mode

The following registers are used for reporting exceptions taken to Hyp mode:

- The `HSR` holds syndrome information for the exception.
- The `HDFAR` holds the VA associated with a Data Abort exception.
- The `HIFAR` holds the VA associated with a Prefetch Abort exception.
- The `HPFAR` holds bits[39:12] of the IPA associated with some aborts on stage 2 address translations.

In addition, if implemented, the optional `HADFSR` and `HAIFSR` can provide additional fault information, see [Hyp Auxiliary Fault Syndrome Registers](#).

Hyp Auxiliary Fault Syndrome Registers

EL2 also defines encodings for the following Hyp Auxiliary Fault Syndrome Registers:

- The Hyp Auxiliary Data Fault Syndrome Register, `HADFSR`.
- The Hyp Auxiliary Instruction Fault Syndrome Register, `HAIFSR`.

An implementation can use these registers to return additional fault status information for aborts taken to Hyp mode. They are the Hyp mode equivalents of the registers described in *Auxiliary Fault Status Registers* on page G4-4125. An example use of these registers is to return more information for diagnosing parity or ECC errors.

The architectural requirements for the [HADFSR](#) and [HAIFSR](#) are:

- The position of these registers is architecturally-defined, but the content and use of the registers is IMPLEMENTATION DEFINED.
- An implementation with no requirement for additional fault reporting can implement these registers as UNK/SBZP, but the architecture does not require it to do so.

Memory fault reporting in Hyp mode

Prefetch Abort and Data Abort exceptions taken to Hyp mode report memory faults. For these aborts, the [HSR](#) contains the following fault status information:

- The [HSR.EC](#) field indicates the type of abort, as [Table G4-29](#) shows.
- The [HSR.ISS](#) field holds more information about the abort. In particular:
 - Bits[5:0] of this field hold the STATUS field for the abort, using the encodings defined in *PL1 fault reporting with the Long-descriptor translation table format* on page G4-4129.
 - Other subfields of the ISS give more information about the exception, equivalent to the information returned in the FSR for a memory fault reported at PL1.

See the descriptions of the ISS fields for the memory faults, referenced from the *Syndrome description* column of [Table G4-29](#), for information about the returned fault information.

Table G4-29 HSR.EC encodings for aborts taken to Hyp mode

| HSR.EC | Abort | Syndrome description |
|--------|--|--|
| 0x20 | Prefetch Abort taken from Non-secure PL0 or PL1 mode | <i>ISS encoding for an exception from a Prefetch Abort on page G6-4406</i> |
| 0x21 | Prefetch Abort taken from Hyp mode | |
| 0x24 | Data Abort taken from Non-secure PL0 or PL1 mode | <i>ISS encoding for an exception from a Data Abort on page G6-4408</i> |
| 0x25 | Data Abort taken from Hyp mode | |

For more information, see *Use of the HSR* on page G4-4137.

A Prefetch Abort exception is taken synchronously with the instruction that the abort is reported on. This means:

- If the PE attempts to execute the instruction a Prefetch Abort exception is generated.
- If an instruction fetch is issued but the PE does not attempt to execute the prefetched instruction, no Prefetch Abort exception is generated for that instruction. For example, if the execution flow branches round a prefetched instruction that would abort if the PE attempted to execute it, no Prefetch Abort exception is generated.

Register updates on exception reporting in Hyp mode

The use of the [HSR](#), and of the other registers listed in *Registers used for reporting exceptions taken to Hyp mode* on page G4-4134, depends on the cause of the Abort. In reporting these faults, in general:

- If the fault generates a synchronous Data Abort exception, the [HDFAR](#) holds the associated VA, but see *Fault address reporting on synchronous external aborts* on page G4-4124 for a permitted exception to this requirement.
- If the fault generates a Prefetch Abort exception, the [HIFAR](#) holds the associated VA, but see *Fault address reporting on synchronous external aborts* on page G4-4124 for a permitted exception to this requirement.

- In the following cases, the **HPFAR** holds the faulting IPA:
 - A Translation or Access flag fault on a stage 2 translation.
 - A Translation, Access flag, or Permission fault on the stage 2 translation of an address accessed in a stage 1 translation table walk.
 - A stage 2 Address size fault.

In all other cases, the **HPFAR** is UNKNOWN.

- On a Data Abort exception that is taken to Hyp mode, the **HIFAR** is UNKNOWN.
- On a Prefetch Abort exception that is taken to Hyp mode, the **HDFAR** is UNKNOWN.

In addition, the reporting of particular aborts is as follows:

Abort on the stage 1 translation for a memory access from Hyp mode

The **HDFAR** or **HIFAR** holds the VA that caused the fault. The STATUS subfield of **HSR.ISS** indicates the type of fault, Translation, Address size, Access flag, or Permission. The **HPFAR** is UNKNOWN.

Abort on the stage 2 translation for a memory access from a Non-secure PL1 or PL0 mode

This includes aborts on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation. The **HDFAR** or **HIFAR** holds the VA that caused the fault. The STATUS subfield of **HSR.ISS** indicates the type of fault, Translation, Address size, Access flag, or Permission.

For any Access flag fault or Translation fault, and also for any Permission fault on the stage 2 translation of a memory access made as part of a translation table walk for a stage 1 translation, the **HPFAR** holds the IPA that caused the fault. Otherwise, the **HPFAR** is UNKNOWN.

Abort caused by a synchronous external abort, or synchronous parity or ECC error, and taken to Hyp mode

The **HDFAR** or **HIFAR** holds the VA that caused the fault, but see [Fault address reporting on synchronous external aborts on page G4-4124](#) for a permitted exception to this requirement. The **HPFAR** is UNKNOWN.

Data Abort caused by a Watchpoint exception and routed to Hyp mode because HDCR.TDE is set to 1

When **HDCR.TDE** is set to 1, a Watchpoint exception generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Data Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

HDFAR is set to the address that generated the watchpoint.

Note

ELR_hyp indicates the address of the instruction that triggered the watchpoint.

A watchpointed address can be any byte-aligned address. The address reported in **HDFAR** might not be the watchpointed address, and, for a watchpoint due to an operation other than a Data Cache maintenance instruction, can be any address between and including:

- The lowest address accessed by the instruction that triggered the watchpoint.
- The highest watchpointed address accessed by that instruction.

If multiple watchpoints are set in this range, there is no guarantee of which watchpoint is generated.

Note

In particular, there is no guarantee of generating the watchpoint with the lowest address in the range.

The address must also be within a naturally-aligned block of memory of an IMPLEMENTATION DEFINED power-of-two size, containing a watchpoint address accessed by that location.

Note

The IMPLEMENTATION DEFINED power-of-two size must be no larger than the block size of the AArch64 [DC ZVA](#) operation.

See also [Watchpoint exceptions](#) on page G2-3961.

In all cases, [HPFAR](#) is UNKNOWN.

Prefetch Abort caused by a Breakpoint Instruction exception and taken to Hyp mode

This abort is generated if a BKPT instruction is executed in Hyp mode. The abort leaves the [HIFAR](#) and [HPFAR](#) UNKNOWN.

See also [Breakpoint Instruction exceptions](#) on page G2-3935.

Prefetch Abort caused by a Breakpoint Instruction, Breakpoint, or Vector Catch exception, and routed to Hyp mode because HDCR.TDE is set to 1

When [HDCR.TDE](#) is set to 1, a debug exception, generated in a Non-secure PL1 or PL0 mode, that would otherwise generate a Prefetch Abort exception, is routed to Hyp mode and generates a Hyp Trap exception.

The abort leaves the [HIFAR](#) and [HPFAR](#) UNKNOWN. This is identical to the reporting of a Prefetch Abort exception caused by a Debug exception on a BKPT instruction that is executed in Hyp mode.

Note

The difference between these two cases is:

- The Debug exception on a BKPT instruction executed in Hyp mode generates a Prefetch Abort exception, taken to Hyp mode, and reported in the [HSR](#) using EC value 0x21.
- Aborts generated because [HDCR.TDE](#) is set to 1 generate a Hyp Trap exception, and are reported in the [HSR](#) using EC value 0x20.

Use of the HSR

The [HSR](#) holds syndrome information for any synchronous exception taken to Hyp mode. Compared with the reporting of exceptions taken to PL1 modes, the [HSR](#):

- Always provides details of the fault. The [DFSR](#) and [IFSR](#) are not used.
- Provides more extensive information, for a wider range of exceptions.

Note

IRQ and FIQ exceptions taken to Hyp mode do not report any syndrome information in the [HSR](#).

[HSR, Hyp Syndrome Register](#) on page G6-4393 describes the [HSR](#), this section summarizes the general form of the register, to show how it encodes exception syndrome information. The register comprises:

- A 6-bit Exception class field, EC, that indicates the cause of the exception.
- An instruction length bit, IL. When an exception is caused by trapping an instruction to Hyp mode, this bit indicates the length of the trapped instruction, as follows:

| | |
|----------|-----------------------------|
| 0 | 16-bit instruction trapped. |
| 1 | 32-bit instruction trapped. |
- An instruction specific syndrome field, ISS. Architecturally, this field could be defined independently for each defined Exception class (EC), but in practice several ISS formats are common to more than one [EC](#).

The format of the HSR depends on the value of the EC field, as follows:

0b000000 < EC ≤ 0b001100

The ISS part of the returned value includes the CV and COND fields described in [Encoding of ISS\[24:20\] when 0b000000 < EC ≤ 0b001100](#). Figure G4-19 shows the HSR format in this case.

Figure G4-19 HSR format when the ISS includes CV and COND fields

EC == 0b000000 or EC 0b001100 There are no generic fields within the ISS. Figure G4-20 shows the HSR format in this case.

Figure G4-20 HSR format when the ISS does not include a COND field

Encoding of ISS[24:20] when 0b000000 < EC ≤ 0b001100

For EC values that are nonzero and less than or equal to 0b001100, ISS[24:20] provides the condition code field for the trapped instruction, together with a valid flag for this field. The encoding of this part of the ISS field is:

- CV, ISS[24]** Condition code valid. Possible values of this bit are:
 - 0** The COND field is not valid.
 - 1** The COND field is valid

COND, ISS[23:20]

The condition code for the trapped instruction. This field is valid only when CV is set to 1. If CV is set to 0, this field is UNK/SBZP.

The full descriptions of the HSR.ISS formats give more information about the CV field.

Note

In some circumstances, it is IMPLEMENTATION DEFINED whether a conditional instruction that fails its condition code check generates an Undefined Instruction exception, see [Conditional execution of undefined instructions on page G1-3851](#).

HSR exception classes

Table G4-30 shows the encoding of the HSR exception class field, EC. Values of EC not shown in the table are reserved. For each EC value, the table references a subsection of the description of the HSR that describes the associated ISS format and gives information about the cause of the exception, for example the configuration required to enable the associated trap.

Table G4-30 HSR.EC field encoding

| EC | Exception class | ISS description, or notes |
|----------|--|--|
| 0b000000 | Unknown reason | <i>ISS encoding for exceptions with an unknown reason on page G6-4396.</i> |
| 0b000001 | Trapped WFI or WFE instruction | <i>ISS encoding for an exception from a WFI or WFE instruction on page G6-4397.</i> |
| 0b000011 | Trapped MCR or MRC access with (coproc==0b1111) | <i>ISS encoding for an exception from an MCR or MRC access on page G6-4398.</i> |
| 0b000100 | Trapped MCRR or MRRC access with (coproc==0b1111) | <i>ISS encoding for an exception from an MCRR or MRRC access on page G6-4400.</i> |
| 0b000101 | Trapped MCR or MRC access with (coproc==0b1110) | <i>ISS encoding for an exception from an MCR or MRC access on page G6-4398.</i> |
| 0b000110 | Trapped LDC or STC access | <i>ISS encoding for an exception from an LDC or STC instruction on page G6-4401.</i> |
| 0b000111 | Advanced SIMD or floating-point functionality trapped by a HCPTR.{TASE, TCP10} control | <i>ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR on page G6-4403.</i> |
| 0b001000 | Trapped VMRS access, from ID group traps, that is not reported using EC 0b000111 | <i>ISS encoding for an exception from an MCR or MRC access on page G6-4398.</i> This trap is not taken if the HCPTR settings trap the access. |
| 0b001100 | Trapped MRRC access with (coproc==0b1110) | <i>ISS encoding for an exception from an MCRR or MRRC access on page G6-4400.</i> |
| 0b001110 | Illegal exception return to AArch32 state | <i>ISS encoding for an exception from an Illegal state or PC alignment fault on page G6-4408.</i> |
| 0b010001 | Exception on SVC execution in AArch32 state routed to EL2 | <i>ISS encoding for an exception from HVC or SVC instruction execution on page G6-4404.</i> |
| 0b010010 | HVC instruction execution in AArch32 state, when HVC is not disabled | |
| 0b010011 | Trapped execution of SMC instruction in AArch32 state | <i>ISS encoding for an exception from SMC instruction execution on page G6-4405.</i> |
| 0b100000 | Prefetch Abort from a lower Exception level | <i>ISS encoding for an exception from a Prefetch Abort on page G6-4406.</i> |
| 0b100001 | Prefetch Abort taken without a change in Exception level | |
| 0b100010 | PC alignment exception. | <i>ISS encoding for an exception from an Illegal state or PC alignment fault on page G6-4408.</i> |
| 0b100100 | Data Abort from a lower Exception level | <i>ISS encoding for an exception from a Data Abort on page G6-4408.</i> |
| 0b100101 | Data Abort taken without a change in Exception level | |

All EC encodings not shown in Table G4-29 on page G4-4135 are reserved by ARM.

G4.12.6 Summary of register updates on exceptions taken to Hyp mode

For memory system faults that generate exceptions that are taken to Hyp mode, [Table G4-31](#) shows the registers affected by each fault. In this table:

- Yes indicates that the register is updated.
- UNK indicates that the fault makes the register value UNKNOWN.
- A null entry, -, indicates that the fault does not affect the register.

———— **Note** —————

For a list of the MMU faults see [MMU faults in AArch32 state on page G4-4118](#).

Table G4-31 Effect of an exception taken to Hyp mode on the reporting registers

| Fault | HSR | HIFAR | HDFAR | HPFAR |
|---|-----|-------------------------|----------------------|-------|
| Faults reported as Prefetch Abort exceptions: | | | | |
| MMU fault ^a at stage 1. | Yes | Yes | UNK | UNK |
| Translation or Access flag MMU fault ^a at stage 2. | Yes | Yes | UNK | Yes |
| Other ^b MMU fault ^a at stage 2. | Yes | Yes | UNK | UNK |
| Stage 2 MMU fault ^a on a stage 1 translation. | Yes | Yes | UNK | Yes |
| Synchronous external abort on translation table walk. | Yes | Yes | UNK | UNK |
| Synchronous parity or ECC error on translation table walk. | Yes | Yes | UNK | UNK |
| Synchronous external abort. | Yes | IMP DEF ^c | UNK | UNK |
| Synchronous parity or ECC error on memory access. | Yes | Yes | UNK | UNK |
| Fault reported as Data Abort exception: | | | | |
| MMU fault ^a at stage 1. | Yes | UNK | Yes | UNK |
| Translation or Access flag MMU fault ^a at stage 2. | Yes | UNK | Yes | Yes |
| Other ^b MMU fault ^a at stage 2. | Yes | UNK | Yes | UNK |
| Stage 2 MMU fault ^a on a stage 1 translation. | Yes | UNK | Yes | Yes |
| Synchronous external abort on translation table walk. | Yes | UNK | Yes | UNK |
| Synchronous parity or ECC error on translation table walk. | Yes | UNK | Yes | UNK |
| Synchronous external abort. | Yes | UNK | IMP DEF ^c | UNK |
| Synchronous parity or ECC error on memory access. | Yes | UNK | Yes | UNK |
| SError interrupt | Yes | UNK | UNK | UNK |
| SError interrupt from a parity or ECC error on memory access. | Yes | UNK | UNK | UNK |
| Debug exception: | | | | |
| Breakpoint Instruction ^d , generates a Prefetch Abort exception. | Yes | UNK | - | UNK |

Table G4-31 Effect of an exception taken to Hyp mode on the reporting registers (continued)

| Fault | HSR | HIFAR | HDFAR | HPFAR |
|---|-----|-------|-------|-------|
| Debug exception routed to Hyp mode because HDCCR.TDE is set to 1. Generates a Hyp Trap exception. | | | | |
| Breakpoint Instruction or Vector Catch | Yes | UNK | - | UNK |
| Watchpoint | Yes | - | Yes | UNK |

- a. For more information see [Classification of MMU faults taken to Hyp mode](#)
- b. MMU fault other than a Translation fault or an Access flag fault.
- c. IMPLEMENTATION DEFINED. The FnV bit in the HSR.ISS field indicates whether the register holds a valid address. See [Fault address reporting on synchronous external aborts on page G4-4124](#).
- d. All other debug exceptions are not permitted in Hyp mode.

———— **Note** ————

Unlike [Table G4-27 on page G4-4132](#), the Hyp mode fault reporting table does not include an entry for a fault on an instruction cache maintenance instruction. That is because, when the fault is taken to Hyp mode, the reporting indicates the cause of the fault, for example a Translation fault, and ISS.CM is set to 1 to indicate that the fault was on a cache maintenance instruction, see [ISS encoding for an exception from a Data Abort on page G6-4408](#).

Classification of MMU faults taken to Hyp mode

This subsection gives more information about the MMU faults shown in [Table G4-31 on page G4-4140](#).

———— **Note** ————

All MMU faults are synchronous.

The table uses the following descriptions for MMU faults taken to Hyp mode:

MMU fault at stage 1

This is an MMU fault generated on a stage 1 translation performed in the Non-secure PL2 translation regime.

MMU fault at stage 2

This is an MMU fault generated on a stage 2 translation performed in the Non-secure PL1&0 translation regime.

As the table shows, for the faults in this group:

- Translation and Access flag faults update the [HPFAR](#)
- Permission faults leave the [HPFAR](#) UNKNOWN.

MMU stage 2 fault on a stage 1 translation

This is an MMU fault generated on the stage 2 translation of an address accessed in a stage 1 translation table walk performed in the Non-secure PL1&0 translation regime. For more information about these faults see [Stage 2 fault on a stage 1 translation table walk on page G4-4117](#).

[Figure G4-1 on page G4-4024](#) shows the different translation regimes and associated stages of translation.

G4.13 Address translation instructions

The System register encoding space includes encodings for instructions that either:

- Translate a *virtual address* (VA) to a *physical address* (PA).
- Translate a *virtual address* (VA) to an *intermediate physical address* (IPA).

[Address translation instructions, functional group on page G4-4204](#) summarizes these instructions.

When using the Short-descriptor translation table format, all translations performed by these instructions take account of TEX remap when this is enabled, see [Short-descriptor format memory region attributes, with TEX remap on page G4-4080](#).

An address translation instruction that executes successfully returns the output address, a PA or an IPA, in the [PAR](#). This is a 64-bit register, that can hold addresses of up to 40 bits.

It is IMPLEMENTATION DEFINED whether the address translation instructions return the values held in a TLB or the result of a translation table walk. Therefore, ARM recommends that these instructions are not used at a time when the TLB entries might be different from the underlying translation tables held in memory.

The following sections give more information about these instructions:

- [Address translation instruction naming and operation summary](#).
- [Encoding and availability of the address translation instructions on page G4-4144](#).
- [Determining the PAR format on page G4-4145](#).
- [Handling of faults and aborts during an address translation instruction on page G4-4146](#).

G4.13.1 Address translation instruction naming and operation summary

Some older documentation uses the original names for the address translation instructions that were included in the original ARMv7 documentation. [Table G4-32](#) summarizes the instructions that are available in AArch32 state, and relates the old instruction names to the current names.

Table G4-32 Naming of address translation instructions

| Name | Old name | Description |
|--|---------------------------------------|--|
| ATS1CPR , ATS1CPW , ATS1CUR , ATS1CUW | V2PCWPR, V2PCWPW, V2PCWUR, V2PCWUW | See ATS1Cxx , Address translation stage 1, current security state on page G4-4143 |
| ATS12NSOPR , ATS12NSOPW , ATS12NSOUR , ATS12NSOUW | V2POWPR, V2POWPW, V2POWUR, V2POWUW | See ATS12NSOxx , Address translation stages 1 and 2, Non-secure state only on page G4-4143 |
| ATS1HR , ATS1HW | Not applicable ^a | See ATS1Hx , Address translation stage 1, Hyp mode on page G4-4144 |

a. Instructions are part of EL2 and have no equivalent in the older descriptions.

In an implementation that does not include EL2, there is no distinction between stage 1 translations and stage 1 and 2 combined translations.

For the *stage 1 current state* and *stages 1 and 2 Non-secure state only* instructions, the meanings of the last two letters of the names are:

| | |
|-----------|-----------------------------|
| PR | PL1 mode, read operation. |
| PW | PL1 mode, write operation. |
| UR | User mode, read operation. |
| UW | User mode, write operation. |

———— **Note** —————

User mode can be described as the unprivileged mode. It is the only PL0 mode.

For the *stage 1 Hyp mode* instructions, the last letter of the instruction name is **R** for the read operation and **W** for the write operation.

See also [Encoding and availability of the address translation instructions on page G4-4144](#).

ATS1Cxx, Address translation stage 1, current security state

Any VMSAv8-32 implementation supports the ATS1Cxx instructions. They can be executed by any software executing at PL1 or higher, in either Security state.

The ATS1Cxx instructions are [ATS1CPR](#), [ATS1CPW](#), [ATS1CUR](#), and [ATS1CUW](#). These instructions perform the address translations of the PL1&0 translation regime.

In an implementation that includes EL2, when executed in Non-secure state, these instructions return the IPA that is the output address of the stage 1 translation. [Figure G4-1 on page G4-4024](#) shows the different translation regimes.

———— Note —————

The Non-secure PL1 and PL0 modes have no visibility of the stage 2 address translations, that can be defined only at PL2, and translate IPAs to be PAs.

See [Determining the PAR format on page G4-4145](#) for the format used when returning the result of these instructions.

ATS12NSOxx, Address translation stages 1 and 2, Non-secure state only

A VMSAv8-32 implementation supports the ATS12NSOxx instructions only if it includes EL2. In an implementation that includes EL2, in AArch32 state, they can be executed:

- By software executing in Non-secure state at EL2. This means by software executing in Hyp mode.
- If the implementation includes EL3, when EL3 is using AArch32, by software executing in Secure state at PL1.

The ATS12NSOxx instructions are [ATS12NSOPR](#), [ATS12NSOPW](#), [ATS12NSOUR](#), and [ATS12NSOUW](#).

In an implementation that includes EL3, when EL3 is using AArch64 and EL1 is using AArch32, any execution of an ATS12NSOxx instruction at Secure EL1 is trapped as an exception that is taken to EL3.

In an implementation that does not include EL2, but includes EL3, when EL3 is using AArch32 these instructions are not UNDEFINED but each instruction behaves in the same way as the equivalent [ATS1Cxx](#) instruction.

If an implementation does not include EL2 and does not include EL3 then these instructions are CONSTRAINED UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see [Unallocated System register access instructions on page K1-5460](#).

ARM deprecates use of these instructions from any Secure PL1 mode other than Monitor mode.

In Secure state and in Non-secure Hyp mode these instructions perform the translations made by the Non-secure PL1&0 translation regime.

These instructions always return the PA and final attributes generated by the translation. That is, for an implementation that includes EL2, they return:

- The result of the two stages of address translation for the specified Non-secure input address.
- The memory attributes obtained by the combination of the stage 1 and stage 2 attributes.

———— **Note** —————

From Hyp mode, the [ATS1Cxx](#) and [ATS12NSOxx](#) instructions both return the results of address translations that would be performed in the Non-secure modes other than Hyp mode. The difference is:

- The [ATS1Cxx](#) instructions return the Non-secure PL1 view of the associated address translation. That is, they return the IPA output address corresponding to the VA input address.
- The [ATS12NSOxx](#) instructions return the EL2, or Hyp mode, view of the associated address translation. That is, they return the PA output address corresponding to the VA input address, generated by two stages of translation.

See [Determining the PAR format on page G4-4145](#) for the format used when returning the result of these instructions.

ATS1Hx, Address translation stage 1, Hyp mode

A VMSAv8-32 implementation supports the [ATS1Hx](#) instructions only if it includes EL2. They can be executed by:

- Software executing in Non-secure state at PL2. This means by software executing in Hyp mode.
- Software executing in Secure state in Monitor mode.

The [ATS1Hx](#) instructions are [ATS1HR](#) and [ATS1HW](#). In an implementation that includes EL3, these instructions are CONstrained UNPREDICTABLE if executed in a Secure PL1 mode other than Monitor mode, see [Hyp mode VA to PA address translation instructions on page K1-5476](#).

If an implementation does not include EL2 then these instructions are CONstrained UNPREDICTABLE, with the permitted behavior that the instructions are UNDEFINED, see [Unallocated System register access instructions on page K1-5460](#).

These instructions perform the translations made by the Non-secure EL2 translation regime. The instruction takes a VA input address and returns a PA output address.

These instructions always return a result in a 64-bit format [PAR](#).

G4.13.2 Encoding and availability of the address translation instructions

Software executing at PL0 never has any visibility of the address translation instructions, but software executing at PL1 or higher can use the unprivileged address translation instructions to find the address translations used for memory accesses by software executing at PL0 and PL1.

———— **Note** —————

For information about translations when the stage of address translation is disabled see [The effects of disabling address translation stages on VMSAv8-32 behavior on page G4-4031](#).

[Table G4-33](#) shows the encodings for the address translation instructions, and their availability in different implementations in different PE modes and states.

Table G4-33 Address translation instructions in AArch32 state

| opc1 | CRm | opc2 | Name | Type | Description |
|---|-----|------|-------------------------|------|---|
| All VMSAv8-32 implementations, in all modes, at PL1 or higher, see ATS1Cxx, Address translation stage 1, current security state on page G4-4143 | | | | | |
| 0 | c8 | 0 | ATS1CPR | WO | PL1 stage 1 read translation, current state |
| | | 1 | ATS1CPW | WO | PL1 stage 1 write translation, current state |
| | | 2 | ATS1CUR | WO | Unprivileged stage 1 read translation, current state |
| | | 3 | ATS1CUW | WO | Unprivileged stage 1 write translation, current state |

Table G4-33 Address translation instructions in AArch32 state (continued)

| opc1 | CRm | opc2 | Name | Type | Description |
|---|-----|------|----------------------------|------|---|
| Implementation includes EL2, in Non-secure Hyp mode and Secure PL1 modes, see ATS12NSOxx , <i>Address translation stages 1 and 2, Non-secure state only</i> on page G4-4143 | | | | | |
| 0 | c8 | 4 | ATS12NSOPR | WO | Non-secure PL1 stage 1 and 2 read translation |
| | | 5 | ATS12NSOPW | WO | Non-secure PL1 stage 1 and 2 write translation |
| | | 6 | ATS12NSOUR | WO | Non-secure unprivileged stage 1 and 2 read translation |
| | | 7 | ATS12NSOUW | WO | Non-secure unprivileged stage 1 and 2 write translation |
| Implementation includes EL2, in Non-secure Hyp mode and Secure Monitor mode, see ATS1Hx , <i>Address translation stage 1, Hyp mode</i> on page G4-4144 | | | | | |
| 4 | c8 | 0 | ATS1HR | WO | Hyp mode stage 1 read translation |
| | | 1 | ATS1HW | WO | Hyp mode stage 1 write translation |

The result of an instruction is always returned in the [PAR](#). The [PAR](#) is a RW register and:

- In all implementations, the 32-bit format [PAR](#) is accessed using an MCR or MRC instruction with CRn set to c7, CRm set to c4, and opc1 and opc2 both set to 0.
- The 64-bit format [PAR](#) is accessed using an MCRR or MRRC instruction with CRm set to c7, and opc1 set to 0.

Address translation instructions that are not available in a particular implementation are reserved and CONSTRAINED UNPREDICTABLE. For example:

- In an implementation that does not include EL2, the encodings with an opc1 value of 4 are reserved and CONSTRAINED UNPREDICTABLE. These are the [ATS1Hx](#) operations.
- In an implementation that does not include either EL2 or EL3, the encodings with opc2 values of 4-7 are reserved and CONSTRAINED UNPREDICTABLE. These are the [ATS12NSOxx](#) operations.

The CONSTRAINED UNPREDICTABLE behavior of these encodings is that they are UNDEFINED, see [Unallocated System register access instructions](#) on page K1-5460.

G4.13.3 Determining the [PAR](#) format

The [PAR](#) is a 64-bit register, that supports both 32-bit and 64-bit [PAR](#) formats. This section describes how the [PAR](#) format is determined, for returning a result from each of the groups of address translation instructions. The returned result might be the translated address, or might indicate a fault on the translation, see [Handling of faults and aborts during an address translation instruction](#) on page G4-4146.

ATS1Cxx instructions

Address translations for the current state. From modes other than Hyp mode:

- [TTBCR.EAE](#) determines whether the result is returned using the 32-bit or the 64-bit [PAR](#) format.
- If the implementation includes EL3, the translation performed is for the current security state and, depending on that state:
 - The Secure or Non-secure [TTBCR.EAE](#) determines the [PAR](#) format.
 - The result is returned to the Secure or Non-secure instance of the [PAR](#)

Instructions executed in Hyp mode always return a result to the Non-secure [PAR](#), using the 64-bit format.

ATS12NSOxx instructions

Address translations for the Non-secure PL1 and PL0 modes. These instructions return a result using the 64-bit [PAR](#) format if at least one of the following is true:

- The Non-secure [TTBCR.EAE](#) bit is set to 1.
- The implementation includes EL2, and the value of [HCR.VM](#) is 1.

Otherwise, the instruction returns a result using the 32-bit [PAR](#) format.

Instructions executed in a Secure PL1 mode return a result to the Secure [PAR](#). Instructions executed in Hyp mode return a result to the Non-secure [PAR](#).

ATS1Hx instructions

Address translations from Hyp mode. These instructions always return a result using the 64-bit [PAR](#) format.

Instructions executed in Secure Monitor mode return a result to the Secure [PAR](#). Instructions executed in Non-secure Hyp mode return a result to the Non-secure [PAR](#).

G4.13.4 Handling of faults and aborts during an address translation instruction

When a stage of address translation is enabled, any corresponding address translation instruction requires a translation table lookup, and this might require a translation table walk. However, the input address for the translation might be a faulting address, either because:

- The translation table entries used for the translation indicate a fault.
- A stage 2 fault or an external abort occurs on the required translation table walk.

[VMSAv8-32 memory aborts on page G4-4110](#) describes the faults that might occur on a translation table walk in AArch32 state.

How the fault is handled, and whether it generates an exception, depends on the cause of the fault, as described in:

- [MMU fault on an address translation instruction](#).
- [External abort during an address translation instruction on page G4-4147](#).
- [Stage 2 fault on a current state address translation instruction on page G4-4147](#).

MMU fault on an address translation instruction

In the following cases, an MMU fault on an address translation is reported in the [PAR](#), and no abort is taken. This applies:

- For a faulting address translation instruction executed in Hyp mode, or in a Secure PL1 mode.
- For a faulting address translation instruction executed in a Non-secure PL1 mode, for cases where the fault would generate a stage 1 abort if it occurred on the equivalent load or store operation.

[Using the PAR to report a fault on an address translation instruction on page G4-4147](#) gives more information about how these faults are reported.

————— Note —————

- The Domain fault encodings shown in [Table G4-25 on page G4-4130](#) are used only for reporting a fault on an address translation instruction that uses the 64-bit [PAR](#) format. That is, they are used only in an implementation that includes EL2, and are used for reporting a Domain fault on either:
 - An [ATS1Cxx](#) operation from Hyp mode.
 - An [ATS12NSOxx](#) operation when [HCR.VM](#) is set to 1.These encodings are never used for fault reporting in the [DFSR](#), [IFSR](#), or [HSR](#).
- For an address translation instruction executed in a Non-secure PL1 mode, for a fault that would generate a stage 2 abort if it occurred on the equivalent load or store operation, the stage 2 abort is generated as described in [Stage 2 fault on a current state address translation instruction on page G4-4147](#).

Using the PAR to report a fault on an address translation instruction

For a fault on an address translation instruction for which no abort is taken, the PAR is updated with the following information, to indicate the fault:

- The fault code, that would normally be written to the Fault status register. The code used depends on the current translation table format, as described in either:
 - [PL1 fault reporting with the Short-descriptor translation table format on page G4-4128.](#)
 - [PL1 fault reporting with the Long-descriptor translation table format on page G4-4129.](#)See also the Note at the start of [Determining the PAR format on page G4-4145](#) about the Domain fault encodings shown in [Table G4-25 on page G4-4130.](#)
- A status bit, that indicates that the translation operation failed.

The fault does not update any Fault Address Register.

External abort during an address translation instruction

As stated in [External abort on a translation table walk on page G4-4120](#), an external abort on a translation table walk generates a Data Abort exception. The abort can be synchronous or asynchronous, and behaves as follows:

Synchronous external abort on a translation table walk

The fault status and fault address registers of the Security state to which the abort is taken are updated. The fault status register indicates the appropriate external abort on a Translation fault, and the fault address register indicates the input address for the translation.

The PAR is UNKNOWN.

Asynchronous external abort on a translation table walk

The fault status register of the Security state to which the abort is taken is updated, to indicate the asynchronous external abort. No fault address registers are updated.

The PAR is UNKNOWN.

Stage 2 fault on a current state address translation instruction

If the PE is in a Non-secure PL1 mode and performs one of the ATStC** operations, then a fault in the stage 2 translation of an address accessed in a stage 1 translation table lookup generates an exception. This is equivalent to the case described in [Stage 2 fault on a stage 1 translation table walk on page G4-4117](#). When this fault occurs on an ATStC** address translation instruction:

- A Hyp Trap exception is taken to Hyp mode.
- The PAR is UNKNOWN.
- The HSR indicates that:
 - The fault occurred on a translation table walk.
 - The operation that faulted was a cache maintenance instruction.
- The HPFAR holds the IPA that faulted.
- The HDFAR holds the VA that the executing software supplied to the address translation instruction.

G4.14 About the System registers for VMSAv8-32

The System registers and System instructions that are accessible in AArch32 state are almost all in the encoding space described in *The AArch32 System register interface* on page G1-3877. This section gives general information about these registers, which comprise:

- Registers in the (coproc==0b1111) encoding space, that provide control and status information for the PE in Non-debug state.
- Registers in the (coproc==0b1110) encoding space, including:
 - Debug registers.
 - Trace registers.
 - Legacy execution environment registers.

VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space on page G4-4172 summarizes the registers in the (coproc==0b1110) encoding space, and indicates where these registers are described, either in this manual or in other architecture specifications.

VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space on page G4-4175 summarizes the registers in the (coproc==0b1111) encoding space, and indicates where in this manual these registers are described.

This section gives general information about the AArch32 System registers, and the conventions used in describing these registers.

———— Note —————

Many implementations include other interfaces to some System registers, for example a memory-mapped interface to some debug System registers. These are described in the appropriate sections of this manual.

This section is organized as follows:

- *About AArch32 System register accesses.*
- *General behavior of System registers* on page G4-4151.
- *Classification of System registers* on page G4-4154.
- *Synchronization of changes to AArch32 System registers* on page G4-4163.
- *Fixed values in register diagrams* on page G4-4169.
- *Principles of the ID scheme for fields in ID registers* on page G4-4169.

G4.14.1 About AArch32 System register accesses

The following subsections give more information about accesses to the AArch32 System registers:

- *Ordering of reads of System registers.*
- *Accessing 32-bit System registers* on page G4-4149.
- *Accessing 64-bit System registers* on page G4-4150.

Ordering of reads of System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that the data dependencies between the instructions, specified in *Synchronization of changes to AArch32 System registers* on page G4-4163, are met.

———— Note —————

In particular, System registers holding self-incrementing counts, for example the Performance Monitors counters or the Generic Timer counter or timers, can be read *early*. This means that, for example, if a memory communication is used to communicate a read of the Generic Timer counter, an ISB must be inserted between the read of the memory location used for this communication and the read of the Generic Timer counter if it is required that the Generic Timer counter returns a count value that is later than the memory communication.

Accessing 32-bit System registers

Software accesses most 32-bit System registers using the generic MCR and MRC System register access instructions, specifying some or all of the parameters { coproc, CRn, opc1, CRm, opc2 }, where:

| | |
|--------|---|
| coproc | Identifies the primary region of the System register encoding space. Takes one of the values: p14 Encoded as 0b1110. p15 Encoded as 0b1111. |
| CRn | Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and CRn is the most significant identifier for the required register within that group. In the (coproc==0b1111) encoding space, CRn is the most significant identifier for the required register. |
| opc1 | Takes a value in the range 0-7, encoded as its 3-bit binary value. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and can take the following values: 0 Debug System registers. 1 Trace System registers. 7 Legacy Jazelle System registers. In the (coproc==0b1111) encoding space, opc1 can take any value in the range 0-7. |
| CRm | Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111. |
| opc2 | Takes a value in the range 0-7, encoded as its 3-bit binary value. opc2 is optional in the MCR and MRC instruction syntax, and if no value is specified the encoding defaults to 0b000. |
| Rt | A general-purpose register to hold a 32-bit value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110. |

This means an MCR or MRC access to a specific 32-bit System register uses:

- A unique combination of coproc, CRn, opc1, CRm, and opc2, to specify the required System register.
- A general-purpose register, Rt, for the transferred 32-bit value.

See also:

- [MCR on page F5-2804](#).
- [MRC on page F5-2826](#).

A small number of AArch32 debug System registers are accessed using LDC or STC instructions. In these cases, the register to be accessed is identified in the instruction syntax by the use of p14, c5 where:

| | |
|-----|---|
| p14 | Identifies that the access is to the (coproc==0b1110) encoding space. |
| c5 | Identifies the target debug System register. |

See the instruction descriptions:

- [LDC \(immediate\) on page F5-2695](#).
- [LDC \(literal\) on page F5-2697](#).
- [STC on page F5-3032](#).

The only uses of LDC and STC permitted in ARMv8-A are:

- An LDC access to load data from memory to [DBGDTRTXint](#), see [LDC \(immediate\) on page F5-2695](#) and [LDC \(literal\) on page F5-2697](#).
- An STC access to store data to memory from [DBGDTRRXint](#), see [STC on page F5-3032](#).

A small number of AArch32 System registers are accessed using MRS, MSR, VMRS, or VMSR instructions, see the appropriate register and instruction description for more information, see:

- [MRS](#) on page F5-2830.
- [MSR \(immediate\)](#) on page F5-2840,
- [MSR \(register\)](#) on page F5-2842.
- [VMRS](#) on page F6-3525.
- [VMSR](#) on page F6-3528.

———— **Note** —————

- For example:
 - The [APSR](#), [CPSR](#), and [SPSR](#) are accessed using MRS or MSR instructions.
 - The [MVFR0](#), [MVFR1](#), and [MVFR2](#) are accessed using VMRS or VMSR instructions.
- In addition, the banked register forms of the MRS and MSR instructions can be used to access some System registers associated with PE modes other than the mode in which the PE is currently executing, see [MRS \(Banked register\)](#) on page F5-2832 and [MSR \(Banked register\)](#) on page F5-2836.

Accessing 64-bit System registers

Software accesses a 64-bit System register using the generic MCRR and MRRC System register access instructions, specifying the parameters {coproc, CRm, opc1}, where:

| | |
|--------|---|
| coproc | Identifies the primary region of the System register encoding space. Takes one of the values: p14 Encoded as 0b1110. p15 Encoded as 0b1111. |
| CRm | Takes a value in the range c0-c15, encoded the corresponding 4-bit binary value, 0b0000-0b1111. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and CRm is the most significant identifier for the required register within that group. In the (coproc==0b1111) encoding space, CRm is the most significant identifier for the required register. |
| opc1 | Takes a value in the range 0-15, encoded as its 3-bit binary value. In the (coproc==0b1110) encoding space, the opc1 value identifies the System register functional group, and can take the following values: 0 Debug System registers. 1 Trace System registers. In the (coproc==0b1111) encoding space, opc1 can take any value in the range 0-15. |
| Rt | A general-purpose register to hold bits[31:0] of the value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110. |
| Rt2 | A general-purpose register to hold bits[63:32] of the value to transfer to or from the System register. Takes a value in the range R0-R14, encoded as the corresponding 4-bit binary value, 0b0000-0b1110. |

This means an MCRR or MRRC access to a specific 64-bit System register uses:

- A unique combination of coproc, CRm and opc1, to specify the required 64-bit System register.
- Two general-purpose registers, each holding 32 bits of the value to transfer.

This means a PE can access a 64-bit System register using:

- An MCRR instruction to write to a System register, see [MCRR](#) on page F5-2806.
- An MRRC instruction to read a System register, see [MRRC](#) on page F5-2806.

When using an MCRR or MRRC instruction the System register access is 64-bit atomic.

Some 64-bit registers also have an MCR and MRC encoding. The MCR and MRC encodings for these registers access the least significant 32 bits of the register. For example, to access the [PAR](#), software can:

- Use the following instructions to access all 64 bits of the register:
MRRC p15, 0, <Rt>, <Rt2>, c7 ; Read 64-bit PAR into Rt (low word) and Rt2 (high word)
MCRR p15, 0, <Rt>, <Rt2>, c7 ; Write Rt (low word) and Rt2 (high word) to 64-bit PAR

- Use the following instructions to access the least-significant 32 bits of the register:
 MRC p15, 0, <Rt>, c7, c4, 0 ; Read PAR[31:0] into Rt
 MCR p15, 0, <Rt>, c7, c4, 0 ; Write Rt to PAR[31:0]

G4.14.2 General behavior of System registers

Except where indicated, System registers are 32-bits wide. As stated in *About AArch32 System register accesses on page G4-4148*, there are some 64-bit registers, and these include cases where software can access either a 32-bit view or a 64-bit view of a register. The register summaries, and the individual register descriptions, identify the 64-bit registers and how they can be accessed.

The following sections give information about the general behavior of these registers. Unless otherwise indicated, information applies to all AArch32 System registers:

- *Read-only bits in read/write registers.*
- *UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses.*
- *Read-only and write-only register encodings on page G4-4153.*
- *Reset behavior of AArch32 System registers on page G4-4153.*

See also *About AArch32 System register accesses on page G4-4148* and *Fixed values in register diagrams on page G4-4169*.

Read-only bits in read/write registers

Some read/write registers include bits that are read-only. These bits ignore writes.

An example of this is the `SCTLR.NMFI` bit, `SCTLR[27]`.

UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for AArch32 System register accesses

This section defines UNPREDICTABLE and UNDEFINED behaviors for accesses to System registers, including those cases where the ARMv8 behavior is CONSTRAINED UNPREDICTABLE.

In AArch32 state the following operations are UNDEFINED:

- All LDC and STC accesses, except for the LDC access to `DBGDTRTXint` and the STC access to `DBGDTRRXint` specified in *Table G4-44 on page G4-4174*.
- All MCRR and MRRC operations to the (coproc==0b111x) encoding space, except for those explicitly defined as accessing 64-bit System registers specified in *Table G4-43 on page G4-4173* and *Table G4-45 on page G4-4179*.

Unless otherwise indicated in the individual register descriptions:

- Reserved fields in registers are RES0.
- Assigning a reserved value to a field has a CONSTRAINED UNPREDICTABLE effect, see *Reserved values in System and memory-mapped registers and translation table entries on page K1-5477*.

The following subsections give more information about UNPREDICTABLE, CONSTRAINED UNPREDICTABLE, and UNDEFINED behavior for accesses to the (coproc==0b111x) encoding space:

- *Accesses to unallocated encodings in the (coproc==0b111x) encoding space.*
- *Additional rules for MCR and MRC accesses to System registers on page G4-4152.*
- *Effects of EL3 and EL2 on System register accesses on page G4-4152.*

Accesses to unallocated encodings in the (coproc==0b111x) encoding space

In ARMv8-A, accesses to unallocated register encodings in the (coproc==0b111x) encoding space are UNDEFINED, see *Unallocated System register access instructions on page K1-5460*.

Additional rules for MCR and MRC accesses to System registers

The following operations are CONstrained UNPREDICTABLE for all encodings in the (coproc==0b111x) encoding space:

- All MCR operations from the PC.
- All MRC operations to APSR_nzcv, except for the (coproc==0b1110) MRC operation to APSR_nzcv from [DBGDSCRint](#).

The CONstrained UNPREDICTABLE behavior of these operations is that they are UNDEFINED, see [Unallocated System register access instructions on page K1-5460](#).

For registers and operations that are accessible from a particular Privilege level, any attempt to access those registers from a lower Privilege level is UNDEFINED.

Some individual registers can be made inaccessible by setting configuration bits, possibly including IMPLEMENTATION DEFINED configuration bits, to disable access to the register. The effects of the architecturally-defined configuration bits are defined individually in this manual. Unless explicitly stated otherwise in this manual, setting a configuration bit to disable access to a register results in the register becoming UNDEFINED for MRC and MCR accesses.

See also [Read-only and write-only register encodings on page G4-4153](#).

Effects of EL3 and EL2 on System register accesses

EL2 and EL3 introduce classes of System registers, described in [Classification of System registers on page G4-4154](#). Some of these classes of register are either:

- Accessible only from certain modes or states.
- Accessible from certain modes or states only when configuration settings permit the access.

Accesses to these registers that are not permitted are UNDEFINED, meaning execution of the register access instruction generates an Undefined Instruction exception.

Note

This section applies only to registers that are accessible from some modes and states. That is, it applies only to register access instructions using an encoding that, under some circumstances, would perform a valid register access.

The following register classes restrict access in this way:

Restricted access System registers

This register class is defined in any implementation that includes EL3.

Restricted access registers other than the [NSACR](#) are accessible only from Secure EL3 modes. All other accesses to these registers are UNDEFINED.

The [NSACR](#) is a special case of a Restricted access register and:

- The [NSACR](#) is:
 - Read/write accessible from Secure PL1 modes.
 - Is Read-only accessible from Non-secure PL2 and PL1 modes.
- All other accesses to the [NSACR](#) are UNDEFINED.

For more information, including behavior when EL3 is using AArch64 or is not implemented, see [Restricted access System registers on page G4-4156](#).

Configurable access System registers

This register class is defined in any implementation that includes EL3.

Most Configurable access registers are accessible from Non-secure state only if control bits in the [NSACR](#) permit Non-secure access to the register. Otherwise, a Non-secure access to the register is UNDEFINED.

For other Configurable access registers, control bits in the **NSACR** control the behavior of bits or fields in the register when it is accessed from Non-secure state. That is, Non-secure accesses to the register are permitted, but the **NSACR** controls how they behave. The only architecturally-defined register of this type is the **CPACR**.

For more information, see *Configurable access System registers* on page G4-4157.

EL2-mode System registers

This register class is defined only in an implementation that includes EL2.

EL2-mode registers are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode when **SCR.NS** is set to 1.

All other accesses to these registers are UNDEFINED.

For more information, see *Hyp mode read/write registers in the (coproc==0b1111) encoding space* on page G4-4157 and *Hyp mode encodings for shared (coproc==0b1111) System registers* on page G4-4159.

EL2-mode write-only operations

This register class is defined only in an implementation that includes EL2.

EL2-mode write-only operations are accessible only from:

- The Non-secure EL2 mode, Hyp mode.
- Secure Monitor mode, regardless of the value of **SCR.NS**.

Write accesses to these operations are:

- CONSTRAINED UNPREDICTABLE in Secure EL3 modes other than Monitor mode.
- UNDEFINED in Non-secure modes other than Hyp mode.

For more information, see *Hyp mode (coproc==0b1111) write-only System instructions* on page G4-4159.

In addition, in any implementation that includes EL3, when EL3 is using AArch32, if write access to a register is disabled by the **CP15SSDISABLE** signal then any MCR access to that register is UNDEFINED.

Read-only and write-only register encodings

Some System registers are *read-only* (RO) or *write-only* (WO). For example:

- Most identification registers are read-only.
- Most encodings that perform an operation, such as a cache maintenance instruction, are write-only.

If a particular Privilege level defines a register to be:

- RO, then any attempt to write to that register, at that Privilege level, is UNDEFINED. This means that any access to that register with $L == 0$ is UNDEFINED.
- WO, then any attempt to read from that register, at that Privilege level, is UNDEFINED. This means that any access to that register with $L == 1$ is UNDEFINED.

For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED.

————— **Note** —————

This section applies only to registers that this manual defines as RO or WO. It does not apply to registers for which other access permissions are explicitly defined.

Reset behavior of AArch32 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.

- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception Level that is using AArch32, see:

- [PE state on reset into AArch32 state on page G1-3869](#).
- The appropriate Trace architecture specification, for the Trace System registers.

When the PE resets into an Exception Level that is using AArch64, PE state that relates to execution in AArch32 state, including the System register values, is UNKNOWN. The only exception to this is state that applies to execution in both AArch64 state and AArch32 state and that has a defined reset value on the reset into AArch64 state. An example of such PE state is the [EDPRSR.SR](#) bit.

For a PE reset into an Exception level that is using AArch32, the architecture defines which AArch32 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and [PE state on reset into AArch32 state on page G1-3869](#) summarizes these architectural requirements. Otherwise, RW registers reset to an architecturally UNKNOWN value.

———— **Note** —————

In an implementation that includes EL3, unless this manual explicitly states otherwise, only the Secure instance of a Banked register is reset to the defined value. This means that software must program the Non-secure instance of the register with the required values. Typically, this programming is part of the PE boot sequence.

Pseudocode description of resetting System registers

The [AArch32.ResetControlRegisters\(\)](#) pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and [PE state on reset into AArch32 state on page G1-3869](#).

———— **Note** —————

For debug and trace System registers this function resets registers as defined for the appropriate level of reset.

G4.14.3 Classification of System registers

Features provided by EL3 and EL2 integrate with many features of the architecture. Therefore, the descriptions of the individual System registers include information about how these Exception levels affect the register. This section:

- Summarizes how EL3 and EL2 affect the implementation of the System registers, and the classification of those registers.
- Summarizes how EL3 controls access to the System registers.
- Describes an EL3 signal that can control access to some registers in the (coproc==0b1111) encoding space.

It contains the following subsections:

- [Banked System registers on page G4-4155](#).
- [Restricted access System registers on page G4-4156](#).
- [Configurable access System registers on page G4-4157](#).
- [EL2-mode System registers on page G4-4157](#).
- [Common System registers on page G4-4160](#).
- [The CP15SDISABLE input signal on page G4-4161](#).

- [Access to registers from Monitor mode on page G4-4162.](#)

Note

EL3 defines the register classifications of Banked, Restricted access, Configurable, and Common. EL2 defines the EL2-mode classification.

It is IMPLEMENTATION DEFINED whether each IMPLEMENTATION DEFINED register is Banked, Restricted access, Configurable, EL2-mode, or Common.

Banked System registers

In an implementation that includes EL3 using AArch32, some System registers are Banked. Banked System registers have two copies, one Secure and one Non-secure. The `SCR.NS` bit selects the Secure or Non-secure instance of the register. [Table G4-34](#) shows which registers in the (`coproc==0b1111`) encoding space are Banked in this way, and the permitted access to each register. No registers in the (`coproc==0b1110`) encoding space are Banked.

Table G4-34 Banked (`coproc==0b1110`) System registers

| Banked register | Permitted accesses ^a |
|---|---|
| CSSELR , Cache Size Selection Register | Read/write only at EL1 or higher |
| SCTLR , System Control Register ^b | Read/write only at EL1 or higher |
| ACTLR , Auxiliary Control Register | Read/write only at EL1 or higher |
| ACTLR2 , Auxiliary Control Register 2 | Read/write only at EL1 or higher. |
| TTBR0 , Translation Table Base 0 | Read/write only at EL1 or higher |
| TTBR1 , Translation Table Base 1 | Read/write only at EL1 or higher |
| TTBCR , Translation Table Base Control | Read/write only at EL1 or higher |
| DACR , Domain Access Control Register | Read/write only at EL1 or higher |
| DFSR , Data Fault Status Register | Read/write only at EL1 or higher |
| IFSR , Instruction Fault Status Register | Read/write only at EL1 or higher |
| ADFSR , Auxiliary Data Fault Status Register | Read/write only at EL1 or higher |
| AIFSR , Auxiliary Instruction Fault Status Register | Read/write only at EL1 or higher |
| DFAR , Data Fault Address Register | Read/write only at EL1 or higher |
| IFAR , Instruction Fault Address Register | Read/write only at EL1 or higher |
| PAR , Physical Address Register | Read/write only at EL1 or higher |
| PRRR , Primary Region Remap Register | Read/write only at EL1 or higher |
| NMRR , Normal Memory Remap Register | Read/write only at EL1 or higher |
| VBAR , Vector Base Address Register | Read/write only at EL1 or higher |
| CONTEXTIDR , Context ID Register | Read/write only at EL1 or higher |
| TPIDRURW , User Read/Write Thread ID | Read/write at all privilege levels, including EL0 |
| TPIDRURO , User Read-only Thread ID | Read-only at EL0 Read/write at EL1 or higher |
| TPIDRPRW , EL1 only Thread ID | Read/write only at EL1 or higher |

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- b. Some bits are common to the Secure and the Non-secure copies of the register, see [SCTLR, System Control Register](#) on page G6-4547.

A Banked System register can contain a mixture of:

- Fields that are Banked.
- Fields that are read-only in Non-secure PL1 or PL2 modes but read/write in the Secure state.

The System Control Register [SCTLR](#) is an example of a register of that contains this mixture of fields.

The Secure copies of the Banked System registers are sometimes referred to as the Secure Banked System registers. The Non-secure copies of the Banked System registers are sometimes referred to as the Non-secure Banked System registers.

Restricted access System registers

In an implementation that includes EL3, some System registers are present only in the Secure security state. These are called *Restricted access* registers, and their read/write access permissions are:

- In Non-secure state, software cannot modify Restricted access registers.
- For the [NSACR](#), in Non-secure state:
 - Software running at PL1 or higher can read the register.
 - Unprivileged software, meaning software running at PL0, cannot read the register.

This means that Non-secure software running at PL1 or higher can read the access permissions for System registers that have Configurable access.

If EL3 is using AArch64 then any read of the [NSACR](#) from Non-secure EL2 using AArch32, or Non-secure EL1 using AArch32, returns the value 0x00000C00.

- For all other Restricted access registers, Non-secure software cannot read the register.

In an implementation that does not include EL3:

- [SDER](#) is implemented only in Secure state.
- Any read of the [NSACR](#) returns the value 0x00000C00.
- All other accesses to Restricted access System registers are UNDEFINED.

[Table G4-35](#) shows the Restricted access System registers in the (coproc==0b1111) encoding space. There are no Restricted access registers in the (coproc==0b1110) encoding space.

Table G4-35 Restricted access (coproc==0b1111) System registers

| Register | Permitted accesses ^a |
|--|---|
| SCR , Secure Configuration | Read/write in Secure PL1 modes |
| SDCR , Secure Debug Configuration Register | Read/write in Secure PL1 modes |
| SDER , Secure Debug Enable | Read/write in Secure PL1 modes |
| NSACR , Non-Secure Access Control | Read/write in Secure PL1 modes Read-only in Non-secure PL1 and PL2 modes |
| MVBAR , Monitor Vector Base Address | Read/write in Secure PL1 modes |

a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

Configurable access System registers

Secure software can configure the access to some System registers. These registers are called Configurable access registers, and the control can be:

- A bit in the control register determines whether the register is:
 - Accessible from Secure state only.
 - Accessible from both Secure and Non-secure states.
- A bit in the control register changes the accessibility of a register bit or field. For example, setting a bit in the control register might mean that a RW field behaves as RAZ/WI when accessed from Non-secure state.

Bits in the [NSACR](#) control access.

In an AArch32 implementation that includes EL3:

- There are no Configurable access System registers in the (coproc==0b1110) encoding space.
- The only required Configurable access register in the (coproc==0b1111) encoding space is the [CPACR](#).
- The following Advanced SIMD and floating point System registers are Configurable access:
 - Floating-point Status and Control Register, [FPSCR](#)
 - Floating-point Exception register, [FPEXC](#).
 - Floating-point System ID register, [FPSID](#).
 - Media and VFP Feature Register 0, [MVFR0](#).
 - Media and VFP Feature Register 1, [MVFR1](#).
 - Media and VFP Feature Register 2, [MVFR2](#).

EL2-mode System registers

In an implementation that includes EL2, if EL2 can use AArch32, the implementation provides a number of registers for use in the EL2 mode, Hyp mode. As with other System register encodings, some of these register encodings provide write-only operations. When the implementation includes EL3 and EL3 is using AArch32, these registers are also accessible from Monitor mode when the value of [SCR.NS](#) is 1.

The following subsections describe the EL2-mode registers:

- *Hyp mode read/write registers in the (coproc==0b1111) encoding space.*
- *Hyp mode encodings for shared (coproc==0b1111) System registers on page G4-4159.*
- *Hyp mode (coproc==0b1111) write-only System instructions on page G4-4159.*

There are no EL2-mode registers in the (coproc==0b1110) encoding space.

Hyp mode read/write registers in the (coproc==0b1111) encoding space

These registers are implemented only in Non-secure state, and in Non-secure state they are accessible only from Hyp mode.

Except for accesses to [CNTVOFF](#) in an implementation that includes EL3 but not EL2, the behavior of accesses to these registers is as follows:

- In Secure state, the registers can be accessed from EL3 when [SCR.NS](#) is set to 1, see *Access to registers from Monitor mode on page G4-4162*.
- The following accesses are UNDEFINED:
 - Accesses from Non-secure PL1 modes.
 - Accesses in Secure state when [SCR.NS](#) is set to 0.

In an implementation that includes EL3 but not EL2, the behavior of accesses to [CNTVOFF](#) is as follows:

- Any access from Secure Monitor mode is CONSTRAINED UNPREDICTABLE, regardless of the value of [SCR.NS](#). The CONSTRAINED UNPREDICTABLE behavior is that the access is UNDEFINED, see *Unallocated System register access instructions on page K1-5460*.
- All other accesses are UNDEFINED.

Note

Except for **CNTVOFF**, the Hyp mode registers are part of EL2, meaning they are implemented only if the implementation includes EL2. However, conceptually, **CNTVOFF** is part of any implementation of the Generic Timer, see *Status of the CNTVOFF register on page G5-4223*. This means the behavior of **CNTVOFF** in an implementation that does not include EL2 is not covered by the general definition of the behavior of the Hyp mode (coproc==0b1111) read/write registers.

Table G4-36 shows the Hyp mode read/write System registers, in the (coproc==0b1111) encoding space:

Table G4-36 Hyp mode (coproc==0b1111) read/write System registers

| Register | Width | Permitted accesses ^a |
|----------------------|--------|---|
| VPIDR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| VMPIDR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HSCTLR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HACTLR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HACTLR2 | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode. |
| HCR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HDCCR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HCPTR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HSTR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HACR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HTCR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| VTCTCR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HTTBR | 64-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| VTTBR | 64-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HADFSR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HAIFSR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HSR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HPFAR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HMAIR0 | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HMAIR1 | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HAMAIRO | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HAMAIR1 | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HVBAR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| HTPIDR | 32-bit | Read/write. In Non-secure state, accessible only from Hyp mode |
| CNTVOFF ^b | 64-bit | Read/write. In Non-secure state, accessible only from Hyp mode |

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
- b. Implemented in any implementation of the Generic Timer. See, also, the Note earlier in this section.

Hyp mode encodings for shared (coproc==0b1111) System registers

Some Hyp mode registers share the Secure instance of an existing Banked register. In this case the implementation includes an encoding for the register that is accessible only in Hyp mode, or in Monitor mode when `SCR.NS` is set to 1.

For these registers, the following accesses are UNDEFINED:

- Accesses from Non-secure PL1 modes.
- Accesses in Secure state when `SCR.NS` is set to 0.

Table G4-37 lists the Hyp mode encodings for shared registers.

Table G4-37 Hyp mode (coproc==0b1111) System register encodings for shared registers

| Register | Permitted accesses ^a | Shared register |
|-----------------------|--|-----------------------------|
| HDFAR | Read/write. Accessible from Hyp mode, or from Monitor mode when <code>SCR.NS</code> is set to 1. | Secure DFAR |
| HIFAR | Read/write. Accessible from Hyp mode, or from Monitor mode when <code>SCR.NS</code> is set to 1. | Secure IFAR |

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.

In Monitor mode, the Secure copies of these registers can be accessed either:

- Using the [DFAR](#) or [IFAR](#) encoding with `SCR.NS` set to 0.
- Using the [HDFAR](#) or [HIFAR](#) encoding with `SCR.NS` set to 1.

However, between accessing a register using one alias and accessing the register using the other alias, a [Context synchronization event](#) is required to ensure the ordering of the accesses.

Hyp mode (coproc==0b1111) write-only System instructions

Architecturally, these encodings are an extension of the Banked register encodings described in [Banked System registers](#) on page G4-4155, where:

- The implementation does not implement the operation in Secure state.
- In Non-secure state, the operation is accessible only at EL2, that is, only from Hyp mode.

In Secure state:

- These instructions can be accessed from Monitor mode regardless of the value of `SCR.NS`, see [Access to registers from Monitor mode](#) on page G4-4162.
- Accesses to these instructions are CONstrained UNpredictable if executed in a Secure mode other than Monitor mode, see [Hyp mode TLB maintenance instructions](#) on page K1-5476 and [Hyp mode VA to PA address translation instructions](#) on page K1-5476.

Accesses to these instructions are UNDEFINED if accessed from a Non-secure PL1 mode.

Table G4-38 shows the EL2-mode write-only instructions in the (coproc==0b1111) encoding space:

Table G4-38 Hyp mode (coproc==0b1111) write-only System instructions

| Register | Width | Permitted accesses ^a |
|-------------------------------|--------|--|
| ATS1HR | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| ATS1HW | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| TLBIALLHIS | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| TLBIMVAHIS | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| TLBIALLNSNHIS | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |

Table G4-38 Hyp mode (coproc==0b1111) write-only System instructions (continued)

| Register | Width | Permitted accesses ^a |
|-------------|--------|--|
| TLBIALLH | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| TLBIMVAH | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |
| TLBIALLNSNH | 32-bit | Write-only. Accessible only from Hyp mode and Monitor mode |

a. This section describes the behavior of write accesses that are not permitted. See also *Read-only and write-only register encodings* on page G4-4153.

For more information about these operations, see *ATSIHx, Address translation stage 1, Hyp mode* on page G4-4144.

Common System registers

Some System registers and operations are common to the Secure and Non-secure Security states. These are described as the *Common access* registers, or simply as the *Common* registers. These registers include:

- Read-only registers that hold configuration information.
- Register encodings used for various memory system operations, rather than to access registers.
- The *ISR*.
- All System registers in the (coproc==0b1110) encoding space.

Table G4-39 shows the Common System registers in the (coproc==0b1111) encoding space. These registers are not affected by whether EL3 is implemented.

Table G4-39 Common (coproc==0b1111) System registers

| Register | Permitted accesses ^a |
|--|---|
| MIDR, Main ID Register | Read-only, only at EL1 or higher |
| CTR, Cache Type Register | Read-only, only at EL1 or higher |
| TCMTR, TCM Type Register ^b | Read-only, only at EL1 or higher |
| TLBTR, TLB Type Register ^b | Read-only, only at EL1 or higher |
| MPIDR, Multiprocessor Affinity Register | Read-only, only at EL1 or higher |
| REVIDR, Revision ID | Read-only, only at EL1 or higher |
| ID_PFR0, ID_PFR1, Processor Feature Registers | Read-only, only at EL1 or higher |
| ID_DFR0, Debug Feature Register 0 | Read-only, only at EL1 or higher |
| ID_AFR0, Auxiliary Feature Register 0 | Read-only, only at EL1 or higher |
| ID_MMFR0-ID_MMFR4, Memory Model Feature Registers | Read-only, only at EL1 or higher |
| ID_ISAR0-ID_ISAR5, Instruction Set Attribute Registers | Read-only, only at EL1 or higher |
| CCSIDR, Cache Size ID Register | Read-only, only at EL1 or higher |
| CLIDR, Cache Level ID Register | Read-only, only at EL1 or higher |
| AIDR, Auxiliary ID Register ^b | Read-only, only at EL1 or higher |
| FCSEIDR, FCSE PID Register | Read/write, only at EL1 or higher |
| Cache and branch predictor maintenance instruction | See <i>Cache maintenance instructions, functional group</i> on page G4-4201 |

Table G4-39 Common (coproc==0b1111) System registers (continued)

| Register | Permitted accesses ^a |
|---|--|
| Address translation instructions | See <i>Address translation instructions, functional group</i> on page G4-4204 |
| CP15DMB , CP15DSB , CP15ISB Data barrier operations | Write-only at all privilege levels, including EL0 |
| TLB maintenance instructions | Write-only, only at EL1 or higher, see <i>TLB maintenance instructions, functional group</i> on page G4-4202 |
| Performance monitors | See <i>Access permissions</i> on page D5-1871 |
| ISR , Interrupt Status Register | Read-only, only at EL1 or higher |

- a. Any attempt to execute an access that is not permitted results in an Undefined Instruction exception.
b. Register or operation details are IMPLEMENTATION DEFINED.

Secure System registers for the (coproc==0b1111) encoding space

The Secure System registers in the (coproc==0b1111) encoding space comprise:

- The Secure copies of the Banked System registers in the (coproc==0b1111) encoding space.
- The Restricted access System registers in the (coproc==0b1111) encoding space.
- The Configurable access System registers in the (coproc==0b1111) encoding space that are configured to be accessible only from Secure state.

In an implementation that includes EL3, the Non-secure System registers are the System registers other than the Secure System registers.

The CP15SDISABLE input signal

When EL3 is using AArch32, it provides an input signal, **CP15SDISABLE**, that disables write access to some of the Secure registers when asserted HIGH. The **CP15SDISABLE** signal has no effect on:

- Register accesses from AArch64 state.
- Register accesses from Secure EL1 when EL3 is using AArch64 and EL1 is using AArch32.

———— Note ————

When EL3 is using AArch32, the interaction between **CP15SDISABLE** and any IMPLEMENTATION DEFINED register is IMPLEMENTATION DEFINED.

[Table G4-40](#) shows the registers and operations affected.

Table G4-40 Secure registers affected by CP15SDISABLE

| Register name | Affected operation |
|---|------------------------------|
| SCTLR , System Control Register | MCR p15, 0, <Rt>, c1, c0, 0 |
| TTBR0 , Translation Table Base Register 0 | MCR p15, 0, <Rt>, c2, c0, 0 |
| TTBCR , Translation Table Base Control Register | MCR p15, 0, <Rt>, c2, c0, 2 |
| DACR , Domain Access Control Register | MCR p15, 0, <Rt>, c3, c0, 0 |
| PRRR , Primary Region Remap Register | MCR p15, 0, <Rt>, c10, c2, 0 |
| NMRR , Normal Memory Remap Register | MCR p15, 0, <Rt>, c10, c2, 1 |

Table G4-40 Secure registers affected by CP15SDISABLE (continued)

| Register name | Affected operation |
|--|------------------------------|
| AMAIRO , Auxiliary Memory Attribute Indirection Register 0 | MCR p15, 0, <Rt>, c10, c3, 0 |
| AMAIR1 , Auxiliary Memory Attribute Indirection Register 1 | MCR p15, 0, <Rt>, c10, c3, 1 |
| VBAR , Vector Base Address Register | MCR p15, 0, <Rt>, c12, c0, 0 |
| MVBAR , Monitor Vector Base Address Register | MCR p15, 0, <Rt>, c12, c0, 1 |

On a reset by the external system that resets the PE into EL3 using AArch32, the **CP15SDISABLE** input signal must be taken LOW. This permits the Reset code to set up the configuration of EL3 features. When the input is asserted HIGH, any attempt to write to the Secure registers shown in [Table G4-40 on page G4-4161](#) results in an Undefined Instruction exception.

The **CP15SDISABLE** input does not affect reading Secure registers, or reading or writing Non-secure registers. It is IMPLEMENTATION DEFINED how the input is changed and when changes to this input are reflected in the PE, and an implementation might not provide any mechanism for driving the **CP15SDISABLE** input HIGH. However, in an implementation in which the **CP15SDISABLE** input can be driven HIGH, changes in the state of **CP15SDISABLE** must be reflected as quickly as possible. Any change must occur before completion of an Instruction Synchronization Barrier operation, issued after the change, is visible to the PE with respect to instruction execution boundaries. Software must perform an Instruction Synchronization Barrier operation meeting the above conditions to ensure all subsequent instructions are affected by the change to **CP15SDISABLE**.

When EL3 is using AArch32, use of **CP15SDISABLE** means key Secure features that are accessible only at PL1 can be locked in a known state. This provides an additional level of overall system security. ARM expects control of **CP15SDISABLE** to reside in the system, in a block dedicated to security.

Access to registers from Monitor mode

When the PE is in Monitor mode, the PE is in Secure state regardless of the value of the [SCR.NS](#) bit. In Monitor mode, the [SCR.NS](#) bit determines whether, for System registers in the (coproc==0b1111) encoding space, valid uses of the MRC, MCR, MRRC and MCRR instructions access the Secure Banked System registers or the Non-secure Banked System registers. That is, when:

NS == 0 Common, Restricted access, and Secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, the registers listed in [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space on page G4-4157](#) and [Hyp mode encodings for shared \(coproc==0b1111\) System registers on page G4-4159](#) are not accessible, and any attempt to access them generates an Undefined Instruction exception.

Note

The operations listed in [Hyp mode \(coproc==0b1111\) write-only System instructions on page G4-4159](#) are accessible in Monitor mode regardless of the value of [SCR.NS](#).

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations performed by these instructions are performed in Secure state.

NS == 1 Common, Restricted access and Non-secure Banked System registers are accessed by MRC, MCR, MRRC and MCRR instructions that target the (coproc==0b1111) encoding space.

If the implementation includes EL2, all the registers and operations listed in the subsections of [EL2-mode System registers on page G4-4157](#) are accessible, using the MRC, MCR, MRRC, or MCRR instructions required to access them from Hyp mode.

System instructions in the (coproc==0b1111) encoding space use the Security state to determine all resources used, that is, all operations by these instructions are performed in Secure state.

The Security state determines whether the Secure or Non-secure Banked registers determine the control state.

———— **Note** —————

Where the contents of a register select the value accessed by an MRC or MCR access to a different register, then the register that is used for selection is being used as control state. For example, [CSSELR](#) selects the current [CCSIDR](#), and therefore [CSSELR](#) is used as control state. Therefore, in Monitor mode:

- [SCR.NS](#) determines whether the Secure or Non-secure [CSSELR](#) is accessible.
- Because the PE is in Secure state, the Secure [CSSELR](#) selects the current [CCSIDR](#).

—————

G4.14.4 Synchronization of changes to AArch32 System registers

In this section, *this PE* means the PE on which accesses are being synchronized.

———— **Note** —————

See [Definitions of direct and indirect reads and writes and their side-effects on page G4-4167](#) for definitions of the terms *direct write*, *direct read*, *indirect write*, and *indirect read*.

—————

A *direct write* to a System register might become visible at any point after the change to the register, but without a [Context synchronization event](#) there is no guarantee that the change becomes visible.

Any direct write to a System register is guaranteed not to affect any instruction that appears, in program order, before the instruction that performed the direct write, and any direct write to a System register must be synchronized before any instruction that appears after the direct write, in program order, can rely on the effect of that write. The only exceptions to this are:

- All direct writes to the same register, using the same encoding, are guaranteed to occur in program order.
- All direct writes to a register are guaranteed to occur in program order relative to all direct reads of the same register using the same encoding.
- Any System register access that an ARM *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- If an instruction that appears in program order before the direct write performs a memory access, such as a memory-mapped register access, that causes an indirect read or write to a register, that memory access is subject to the memory order model. In this case, if permitted by the memory order model, the instruction that appears in program order before the direct write can be affected by the direct write. For information about the memory order model, see [Memory ordering on page E2-2332](#).

These rules mean that an instruction that writes to one of the address translation instructions described in [Address translation instructions on page G4-4142](#) must be explicitly synchronized to guarantee that the result of the address translation instruction is visible in the [PAR](#).

———— **Note** —————

In this case, the direct write to the encoding of the address translation instruction causes an *indirect write* to the [PAR](#). Without a [Context synchronization event](#) after the direct write there is no guarantee that the indirect write to the [PAR](#) is visible.

—————

Conceptually, the explicit synchronization occurs as the first step of any [Context synchronization event](#). This means that if the operation uses the state that had been changed but not synchronized before the operation occurred, the operation is guaranteed to use the state as if it had been synchronized.

———— **Note** —————

- This explicit synchronization is applied as the first step of the execution of any instruction that causes the synchronization operation. This means it does not synchronize any effect of changes to the System registers that might affect the fetch and decode of the instructions that cause the operation, such as breakpoints or changes to translation tables.
- For a synchronous exception, the control state in use at the time the exception is generated determines the exception syndrome information, and this syndrome information is not changed by this synchronization at the start of taking the exception.

Except for the register reads listed in *Registers with some architectural guarantee of ordering or observability* on page G4-4166, if no *Context synchronization event* is performed, direct reads of System registers can occur in any order.

Table G4-41 shows the synchronization requirement between two reads or writes that access the same System register. In the column headings, *First* and *Second* refer to:

- Program order, for any read or write caused by the execution of an instruction by this PE, other than a read or write caused by a memory access made by that instruction.
- The order of arrival of asynchronous reads or writes made by this PE relative to the execution of instructions by this PE.

In addition:

- For indirect reads or writes caused by an external agent, such as a debugger, the mechanism that determines the order of the reads or writes is defined by that external agent. The external agent can provide mechanisms that ensure that any read or write it makes arrives at the PE. These indirect reads and writes are asynchronous to software execution on the PE.
- For indirect reads or writes caused by memory-mapped reads or writes made by this PE, the ordering of the memory accesses is subject to the memory order model, including the effect of the memory type of the accessed memory address. This applies, for example, if this PE reads or writes one of its registers in a memory-mapped register interface.

The mechanism for ensuring completion of these memory accesses, including ensuring the arrival of the asynchronous read or write at the PE, is defined by the system.

———— **Note** —————

Such accesses are likely to be given a Device memory attribute, but requiring this is outside the scope of the architecture.

- For indirect reads or writes caused by autonomous asynchronous events that are counted, for example events caused by the passage of time, the events are ordered so that:
 - Counts progress monotonically.
 - The events arrive at the PE in finite time and without undue delay.

Table G4-41 Synchronization requirements for updates to System registers

| First read or write | Second read or write | <i>Context synchronization event</i> required |
|---------------------|----------------------|---|
| Direct read | Direct read | No |
| | Direct write | No |
| | Indirect read | No ^a |
| | Indirect write | No ^a , but see text in this section for exceptions |

Table G4-41 Synchronization requirements for updates to System registers (continued)

| First read or write | Second read or write | Context synchronization event required |
|---------------------|----------------------|--|
| Direct write | Direct read | No |
| | Direct write | No |
| | Indirect read | Yes ^a |
| | Indirect write | No, but see text in this section for exceptions |
| Indirect read | Direct read | No |
| | Direct write | No |
| | Indirect read | No |
| | Indirect write | No |
| Indirect write | Direct read | Yes, but see text in this section for exceptions |
| | Direct write | No, but see text in this section for exceptions |
| | Indirect read | Yes, but see text in this section for exceptions |
| | Indirect write | No, but see text in this section for exceptions |

- a. Although no synchronization is required between a Direct write and a Direct read, or between a Direct read and an Indirect write, this does not imply that a Direct read causes synchronization of a previous Direct write. This means that the sequence Direct write followed by Direct read followed by Indirect read, with no intervening context synchronization, does not guarantee that the Indirect read observes the result of the Direct write.

If the indirect write is to a register that *Registers with some architectural guarantee of ordering or observability on page G4-4166* shows as having some guarantee of the visibility of an indirect write, synchronization might not be required.

If a direct read or a direct write to a register is followed by an indirect write to that register that is caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the indirect write relative to the direct read or direct write.

If an indirect write caused by a direct write is followed by an indirect write caused by an external agent, or by an autonomous asynchronous event, or as a result of a memory-mapped write, then synchronization is required to guarantee the ordering of the two indirect writes.

If a direct read causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct read, before any subsequent direct or indirect read or write.

If a direct write causes an indirect write, synchronization is required to guarantee that the indirect write is visible to subsequent direct or indirect reads or writes. This synchronization must be performed after the direct write, before any subsequent direct or indirect read or write.

———— **Note** —————

Where a register has more than one encoding, a direct write to the register using a particular encoding is not an indirect write to the same register with a different encoding.

Where an indirect write is caused by the action of an external agent, such as a debugger, or by a memory-mapped read or write by the PE, then an indirect write by that agent to a register using a particular access mechanism, followed by an indirect read by that agent to the same register using the same access mechanism and address does not need synchronization.

For information about the additional synchronization requirements for memory-mapped registers, see *Synchronization requirements for AArch64 System registers on page D7-1889*.

To guarantee the visibility of changes to some registers, additional operations might be required before the *Context synchronization event*. For such a register, the definition of the register identifies these additional requirements.

In this manual, unless the context indicates otherwise:

- *Accessing* a System register refers to a direct read or write of the register.
- *Using* a System register refers to an indirect read or write of the register.

Registers with some architectural guarantee of ordering or observability

For the registers for which Table G4-42 shows that the ordering of direct reads is guaranteed, multiple direct reads of a single register, using the same encoding, occur in program order without any explicit ordering.

For the registers for which Table G4-42 shows that some observability of indirect writes is guaranteed, an indirect write to the register caused by an external agent, an autonomous asynchronous event, or as a result of a memory-mapped write, is both:

- Observable to direct reads of the register, in finite time, without explicit synchronization.
- Observable to subsequent indirect reads of the register without explicit synchronization.

These two sets of registers are similar, as Table G4-42 shows:

Table G4-42 Registers with a guarantee of ordering or observability, VMSAv8-32

| Register | Ordering of direct reads | Observability of indirect writes | Notes |
|--|--------------------------|----------------------------------|--|

In addition to the requirements shown in [Table G4-42 on page G4-4166](#):

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:

- [OSLAR_EL1](#). [OSLAR_EL1](#) is indirectly read to determine whether the subsequent access is permitted.

———— **Note** —————

[OSLAR_EL1](#) maps to the AArch32 System register [DBGOSLAR](#).

- [EDLAR](#), if implemented. [EDLAR](#) is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

———— **Note** —————

This requirements is stricter than the general requirement for the observability of indirect writes.

- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See [DCC and ITR access in Debug state on page H4-4923](#).

The possibility that direct reads can occur *early*, in the absence of context synchronization, described in [Ordering of reads of System registers on page G4-4148](#), still applies to the registers listed in [Table G4-42 on page G4-4166](#).

Definitions of direct and indirect reads and writes and their side-effects

Direct and indirect reads and writes are defined as follows:

Direct read Is a read of a register, using an MRC, MRRC, or STC instruction, that the architecture permits for the current PE state.

If a direct read of a register has a side-effect of changing the value of a register, the effect of a direct read on that register is defined to be an *indirect write*, and has the synchronization requirements of an indirect write. This means the indirect write is guaranteed to have occurred, and to be visible to subsequent direct or indirect reads and writes only if synchronization is performed after the direct read.

———— **Note** —————

The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases.

Direct write Is a write to a register, using an MCR, MCRR, or LDC instruction, that the architecture permits for the current PE state.

In the following cases, the side-effect of the direct write is defined to be an indirect write of the affected register, and has the synchronization requirements of an indirect write:

- If the direct write has a side-effect of changing the value of a register other than the register accessed by the direct write.
- If the direct write has a side-effect of changing the value of the register accessed by the direct write, so that the value in that register might not be the value that the direct write wrote to the register.

In both cases, this means that the indirect write is not guaranteed to be visible to subsequent direct or indirect reads and writes unless synchronization is performed after the direct write.

Note

- As an example of a direct write to a register having an effect that is an indirect write of that register, writing 1 to a [PMCNTENCLR.Px](#) bit is also an indirect write, because if the Px bit had the value 1 before the direct write, the side-effect of the write changes the value of that bit to 0.
- The indirect write described here can affect either the register written to by the direct write, or some other register. The synchronization requirement is the same in both cases. For example, writing 1 to a [PMCNTENCLR.Px](#) bit that is set to 1 also changes the corresponding [PMCNTENSET.Px](#) bit from 1 to 0. This means that the direct write to the [PMCNTENCLR](#) defines indirect writes to both itself and to the [PMCNTENSET](#).

Indirect read Is a use of the register by an instruction to establish the operating conditions for the instruction. Examples of operating conditions that might be determined by an indirect read are the translation table base address, or whether memory accesses are forced to be Non-cacheable.

Indirect reads include situations where the value of one register determines what value is returned by a second register. This means that any read of the second register is an indirect read of the register that determines what value is returned.

Indirect reads also include:

- Reads of the System registers by external agents, such as debuggers, as described in [Debug registers on page G6-4668](#).
- Memory-mapped reads of the System registers made by the PE on which the System registers are implemented.

Where an indirect read of a register has a side-effect of changing the value of a register, that change is defined to be an indirect write, and has the synchronization requirements of an indirect write.

Indirect write Is an update to the value of a register as a consequence of either:

- An exception, operation, or execution of an instruction that is not a direct write to that register.
- The asynchronous operation of an external agent.

This can include:

- The passage of time, as seen in counters or timers, including performance counters.
- The assertion of an interrupt.
- A write from an external agent, such as a debugger.

However, for some registers, the architecture gives some guarantee of visibility without any explicit synchronization, see [Registers with some architectural guarantee of ordering or observability on page G4-4166](#).

Note

Taking an exception is a context-synchronizing operation. Therefore, any indirect write performed as part of an exception entry does not require additional synchronization. This includes the indirect writes to the registers that report the exception, as described in [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#).

G4.14.5 Fixed values in register diagrams

In register diagrams, a fixed bit can be indicated by one of 0, (0), 1, or (1), with the following meanings:

- 0** In any implementation:
- The bit must read as 0.
 - Writes to the bit must be ignored.
 - Software:
 - Can rely on the bit reading as 0.
 - Must use an SBZP policy to write to the bit.
- (0)** The bit should-be-zero. In AArch32 state there are a small number of cases where a bit is (0) in some contexts, and has a different defined behavior in other contexts. See [RES0](#).
- 1** In any implementation:
- The bit must read as 1.
 - Writes to the bit must be ignored.
 - Software:
 - Can rely on the bit reading as 1.
 - Must use an SBOP policy to write to the bit.
- (1)** The bit is should-be-one. In AArch32 state there are a small number of cases where a bit is (1) in some contexts, and has a different defined behavior in other contexts. See [RES1](#).

———— Note —————

In register diagrams, (0) is a synonym for RES0, and (1) is a synonym for RES1, where RES0 and RES1 are defined in the [Glossary](#). However, when used in an instruction encoding diagram, (0) and (1) have the narrower definition that behavior is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE if either:

- A bit marked as (0) has the value 1.
- A bit marked as (1) has the value 0.

G4.14.6 Principles of the ID scheme for fields in ID registers

The ARM architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields*. Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. [AArch32 ID registers to which this scheme applies on page G4-4170](#) identifies the set of ID registers that are accessible from AArch32 state.

———— Note —————

These fields are distinct from register fields that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors, or the amount of memory.

———— Note —————

The presence of an ID register field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, if a value of 0x1 indicates the presence of some instructions, then the value 0x2 will indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {  
    // do something that relies on the value of the feature  
}
```

For ID fields where the value 0x0 defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value 0xF indicates that the feature is not implemented.
- The field value 0x0 indicates that the feature is implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {
    // Software features that depend on the presence of the hardware feature
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. [Example G4-6](#) shows the use of such a field.

Example G4-6 Example of the use of a fractional field

For a field describing some class of functionality:

- The value 0x1 was defined as indicating that item A is present.
- The value 0x2 was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value 0x1 when A and B only are present. This fractional field is valid only when the original ID field has the value 0x1.

This approach means that:

- Software that depends on the test if (value >= 0x2) can rely on features A, B, and C being present,
- Software that depends on the test if (value >= 0x1) can rely on feature A being present.
- If new software needs to check only that features A and B are present then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
    // Software features that depend on A and B only
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

AArch32 ID registers to which this scheme applies

This scheme applies to the following AArch32 system registers:

- The Auxiliary Feature register [ID_AFR0](#).
- The Processor Feature registers [ID_PFR0](#) and [ID_PFR1](#).
- The Debug Feature register [ID_DFR0](#).
- The Memory Model Feature registers [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), and [ID_MMFR4](#).

- The Instruction Set Attribute registers [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), and [ID_ISAR5](#).
- The Media and VFP Feature registers [MVFR0](#), [MVFR1](#), and [MVFR2](#).

———— **Note** —————

Principles of the ID scheme for fields in ID registers on page D7-1893 includes information about the AArch64 System registers and the memory-mapped registers to which this scheme applies.

G4.15 VMSAv8-32 organization of registers in the (coproc==0b1110) encoding space

The System registers in the (coproc==0b1110) encoding space provide a number of distinct control functions, covering:

- Debug.
- Trace.
- Execution environment control, for identification of the trivial Jazelle implementation.

Because these functions are distinct, the descriptions of these registers are distributed, as follows:

- In this manual [Debug registers on page G6-4668](#) describes the Debug registers.
- [The Embedded Trace Macrocell Architecture Specification](#) describes the Trace registers.

This section summarizes the allocation of the System registers in the (coproc==0b1110) encoding space between these different functions, and the register encodings in this space that are reserved.

The 32-bit System register encodings are classified by the {opc1, CRn, opc2, CRm} values required to access them using an MCR or an MRC instruction. The 64-bit System register encodings are classified by the {opc1, CRm} values required to access them using an MCRR or an MRRC instruction. For the registers in the (coproc==0b1110) encoding space, the opc1 value determines the primary allocation of these registers, as follows:

opc1==0 Debug registers.

opc1==1 Trace registers.

opc1==7 Jazelle registers. Jazelle registers are implemented as required for a trivial Jazelle implementation.

Other opc1 values

Reserved.

———— Note ————

Primary allocation of (coproc==0b1110) register function by opc1 value differs from the allocation of (coproc==0b1111) registers, where primary allocation is by CRn value for 32-bit register accesses, or CRm value for 64-bit register accesses.

For the Debug and Jazelle registers, [Table G4-43 on page G4-4173](#) defines:

- The {opc1, CRn, opc2, CRm} values used for accessing the 32-bit registers using the MRC and MCR instructions.
- The {opc1, CRm} values used for accessing the 64-bit register using the MRRC instruction.

Some Debug registers can also be accessed using the LDC and STC instructions. [Table G4-44 on page G4-4174](#) defines the CRn values used for accessing the registers using these instructions.

———— Note ————

The only permitted uses of the LDC and STC instructions are:

- An LDC access to load data from memory to [DBGDTRTXint](#).
- An STC access to store data to memory from [DBGDTRRXint](#).

In the LDC and STC syntax descriptions in this Manual, the required coproc value of p14 and CRn value of c5 are given explicitly.

G4.15.1 Register access instruction arguments, (coproc==0b1110) registers

Table G4-43 shows the MCR, MRC, and MRRC instruction arguments required for accesses to each register that can be visible in the System register interface in the (coproc==0b1110) encoding.

Table G4-43 Mapping of (coproc==0b1110) MCR, MRC, and MRRC instruction arguments to System registers

| opc1 | CRn | opc2 | CRm | Name | Width | Description | | |
|------|--------------------|--------------------|--------------------|--|--------------------|---|---|--|

Table G4-43 Mapping of (coproc==0b1110) MCR, MRC, and MRRC instruction arguments to System registers (continued)

| opc1 | CRn | opc2 | CRm | Name | Width | Description |
|---------------------|-------|------|--------|-------------------------------|--------|--|
| 0 | c7 | 6 | c8 | DBGCLAIMSET | 32-bit | Debug CLAIM Tag Set register |
| | | | c9 | DBGCLAIMCLR | 32-bit | Debug CLAIM Tag Clear register |
| | | | c14 | DBGAUTHSTATUS | 32-bit | Debug Authentication Status register |
| | 7 | | c0 | DBGDEVID2 | 32-bit | Debug Device ID register 2 |
| | | | c1 | DBGDEVID1 | 32-bit | Debug Device ID register 1 |
| | | | c2 | DBGDEVID | 32-bit | Debug Device ID register |
| 1 | c0-c7 | 0-7 | c0-c15 | - | 32-bit | Reserved for OPTIONAL Trace extension |
| 7 | c0 | 0 | c0 | JIDR | 32-bit | Jazelle ID Register ^c |
| | c1 | 0 | c0 | JOSCR | 32-bit | Jazelle OS Control Register ^c |
| | c2 | 0 | c0 | JMCR | 32-bit | Jazelle Main Configuration Register ^c |
| All other encodings | | | | - | 32-bit | Unallocated |

- If EL1 cannot use AArch32 this register is OPTIONAL and deprecated. See the register description for details.
- Not implemented breakpoint and watchpoint register access instructions are unallocated. If EL2 is not implemented or breakpoint *n* is not context-aware, [DBGXVR<n>](#) is unallocated. CRm encodes <*n*>, the breakpoint or watchpoint number.
- Legacy register, see [Legacy feature registers, functional group on page G4-4211](#).

[Table G4-44](#) shows the LDC and STC instruction arguments required for accesses to the Debug registers that can be accessed using these instructions.

Table G4-44 Mapping of LDC and STC instruction arguments to System registers

| CRn | Instruction | Name | Width | Description |
|-----|-------------|-----------------------------|--------|---|
| c5 | LDC | DBGDTRTXint | 32-bit | Debug Data Transfer Register, Transmit, Internal View |
| c5 | STC | DBGDTRRXint | 32-bit | Debug Data Transfer Register, Receive, Internal View |

———— **Note** —————

In the instruction syntax descriptions for the LDC and STC instructions, the required coproc and CRn values are given explicitly as coproc==p14, CRn==c5.

G4.16 VMSAv8-32 organization of registers in the (coproc==0b1111) encoding space

For 32-bit accesses to the System registers in the (coproc==0b1111) encoding space, the ordered set of parameters {CRn, opc1, CRm, opc2} determine the register order. Within this ordering, the CRn value originally provided a functional grouping of these registers. As the number of System registers has increased this ordering has become less appropriate.

This document now:

- Groups the System registers in the (coproc==0b1111) encoding space by functional group, see [Functional grouping of VMSAv8-32 System registers on page G4-4193](#).
- Describes all of the System registers for VMSAv8-32, in [Chapter G6 AArch32 System Register Descriptions](#).
- Gives additional information about the organization of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, in the remainder of this section.

This section presents information as follows:

Register ordering by {CRn, opc1, CRm, opc2}

See:

- [System register summary for \(coproc==0b1111\) encodings by CRn value on page G4-4176](#).
- [Full list of VMSAv8-32 System registers in the \(coproc==0b1111\) encoding space on page G4-4178](#).

Note

The ordered listing of (coproc==0b1111) registers by the {CRn, opc1, CRm, opc2} encoding of the 32-bit registers is most likely to be useful to those implementing AArch32 state, and to those validating such implementations. However, otherwise, the grouping of registers by function is more logical.

Views of the registers, that depend on the current state of the PE

See [AArch32 views of the System registers in the \(coproc==0b1111\) encoding space on page G4-4190](#).

Note

The different register views are particularly significant in implementations that include EL2.

In addition, the indexes in [Appendix K12 Registers Index](#) include all of the System registers.

G4.16.1 System register summary for (coproc==0b1111) encodings by CRn value

Figure G4-21 summarizes the grouping of the System registers in the (coproc==0b1111) encoding space, for a VMSAv8-32 implementation, by the value of CRn used for a 32-bit access to the register.

Figure G4-21 System register groupings for (coproc==0b1111), for 32-bit registers

Note

For the System registers in the (coproc==0b1111) encoding space, Figure G4-21 gives only an overview of the assigned encodings for 32-bit registers for each of the CRn values c0-c15. For more information, see:

- The full list of registers in the (coproc==0b1111) encoding space, in *Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space* on page G4-4178, for the definition of the assigned and unassigned encodings for that register.
- The register definitions in *Chapter G6 AArch32 System Register Descriptions* for any dependencies on the implemented Exception levels.

In general, System register accesses using an unallocated set of {CRn, opc1, CRm, opc2} values are UNDEFINED. *Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0)* on page G4-4177 described the only exceptions to this rule.

The 32-bit System registers with (coproc==0b1111, CRn==c15), and the corresponding 64-bit System registers, are reserved for implementation defined registers. For more information see *Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space* on page G4-4177.

The HSTR.Tn trap on (coproc==0b1111) System registers

As *General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the (coproc==0b1111) encoding space* on page G1-3908 describes, when the value of HSTR.Tn is 1, Non-secure PL1 accesses to System registers in the (coproc==0b1111) encoding space using a CRn or CRm value that corresponds to the value of Tn are trapped to PL2, even if the encoding is UNDEFINED when the value of HSTR.Tn is 0. This applies:

- For 32 bit register accesses when the value of Rn in the MCR or MRC instruction corresponds to Tn.
- For 64 bit register accesses when the value of Rm in the MCRR or MRRC instruction corresponds to Tn.

If there are matching System register encodings that are accessible from Non-secure PL0 then those accesses are also trapped to PL2 when the value of HSTR.Tn is 1.

Behavior of VMSAv8-32 32-bit System registers with (coproc==0b1111, CRn==c0)

In the (coproc==0b1111) encoding space, the 32-bit System registers with (CRn==c0) provide device and feature identification. That is, they provide registers in the functional group described in [Identification registers, functional group](#) on page G4-4194.

[Table G4-45 on page G4-4179](#) shows all of the architecturally required System registers with {coproc==0b1111, CRn==c0}. The behavior of 32-bit System register encodings in this group that are not shown in the table, and encodings that are part of an unimplemented Exception level, depends on the value of opc1, and possibly on the value of CRm and opc2, as follows:

- opc1 == 0 All write accesses to the encodings are UNDEFINED.
For read accesses:
- The following encodings return an UNKNOWN value:
 - CRm==3, opc2=={0, 1, 2}.
 - CRm=={4, 6, 7}, opc2=={0, 1}.
 - CRm==5, opc2=={0, 1, 4, 5}.
 - All other encodings are RES0.
- opc1 > 0 All accesses to the encodings are UNDEFINED.

See also [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space](#) on page G4-4151.

———— Note ————

Some of these registers were previously described as being part of the CPUID identification scheme, see [The CPUID identification scheme](#) on page G4-4195.

Reserved encodings in the VMSAv8-32 System register (coproc==0b1111) space

AArch32 state reserves a number of regions in the (coproc==0b1111) encoding space for IMPLEMENTATION DEFINED System registers. These reservations are defined in terms of the encoding of 32-bit accesses to the System register encoding space. That is, they are defined by the reserved 32-bit {CRn, opc1, CRm, opc2} encodings.

In ARMv8, reserved encodings that do not have an IMPLEMENTATION DEFINED function are UNDEFINED.

The following subsections give more information about these reserved encodings:

- [Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}](#).
- [Reserved 32-bit encodings with {coproc==0b1111, CRn==c10}](#) on page G4-4178.
- [Reserved 32-bit encodings with {coproc==0b1111, CRn==c11}](#) on page G4-4178.
- [Reserved 32-bit encodings with {coproc==0b1111, CRn==c15}](#) on page G4-4178.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c9}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c9}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c9, opc=={0-7}, CRm=={c0-c2, c5-c8}} are reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations.
- Encodings with {coproc==0b1111, CRn==c9, opc=={0-7}, CRm==c15} are reserved for IMPLEMENTATION DEFINED performance monitors.

———— Note ————

These are distinct from the OPTIONAL ARM Performance Monitors Extension, the registers for which use the encoding space {coproc==0b1111, CRn==c9, opc=={0-7}, CRm=={c12-c14}}.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c10}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c10}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c10, opc=={0-7}, CRm=={c0, c1, c4, c8}} are reserved for IMPLEMENTATION DEFINED TLB lockdown operations.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c11}

In the AArch32 encoding space, for 32-bit encodings with {coproc==0b1111, CRn==c11}, the following encodings are reserved for IMPLEMENTATION DEFINED purposes:

- Encodings with {coproc==0b1111, CRn==c11, opc=={0-7}, CRm=={c0-c8, c15}} are reserved for IMPLEMENTATION DEFINED DMA operations for TCM access.

In ARMv8, the remainder of the AArch32 {coproc==0b1111, CRn==c11} encoding space is UNDEFINED.

Reserved 32-bit encodings with {coproc==0b1111, CRn==c15}

ARMv8 reserves the AArch32 System register encodings with (coproc==0b1111, CRn==c15) for IMPLEMENTATION DEFINED purposes, and does not impose any restrictions on the use of these encodings. The documentation of the ARM implementation must describe fully any registers implemented in the {coproc==0b1111, CRn==c15} encoding space. Normally, for processor implementations by ARM, this information is included in the *Technical Reference Manual* for the processor.

Typically, an implementation uses the {coproc==0b1111, CRn==c15} encodings to provide test features, and any required configuration options that are not covered by this Manual.

This reservation means that the AArch32 64-bit encodings with {coproc==0b1111, CRm==c15} are also reserved for IMPLEMENTATION DEFINED purposes, without any restrictions on the use of these encodings.

G4.16.2 Full list of VMSAv8-32 System registers in the (coproc==0b1111) encoding space

Table G4-45 on page G4-4179 shows the System registers in the (coproc==0b1111) encoding space in VMSAv8-32, in the order of the {CRn, opc1, CRm, opc2} parameter values used in MCR or MRC accesses to the 32-bit registers:

- For MCR or MRC accesses to the 32-bit registers, CRn is the primary identifier of the target System register for the access. This applies, also, to MCR or MRC instructions that provide 32-bit accesses to a single word of a 64-bit System register.
- For MCRR or MRRC accesses to the 64-bit registers, CRm is the primary identifier of the target System register for the access. Table G4-45 on page G4-4179 orders the 64-bit registers with the 32-bit registers accessed using the same primary register identifier. For example, the 64-bit encoding of TTBR0, that is accessed with (CRm==c2), is listed with the 32-bit registers that are accessed with (CRn==c2).

Table G4-45 VMSAv8-32 (coproc==0b1111) register summary, in MCR/MRC parameter order

| CRn | opc1 | CRm | opc2 | Name | Width | Description |

| - | 4 | c14 | - | CNTVOFF ^j | 64-bit | Virtual Offset register |
| c14 | 4 | c1 | 0 | CNTHCTL | 32-bit | Timer EL2 Control register |
| | | c2 | 0 | CNTHP_TVAL | 32-bit | EL2 Physical TimerValue register |
| | | | 1 | CNTHP_CTL | 32-bit | EL2 Physical Timer Control register |
| - | 6 | c14 | - | CNTHP_CVAL | 64-bit | EL2 Physical Timer CompareValue register |
| c15 | 0-7 | c0-c15 | 0-7 | - | 32-bit | See Reserved 32-bit encodings with {coproc==0b1111, CRn==c15} on page G4-4178 |

- a. [REVIDR](#) is an optional register. If it is not implemented, the encoding with opc2 set to 6 is an alias of [MIDR](#).
- b. Implemented only as part of EL2, when EL2 is using AArch32. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#).
- c. Implemented only as part of the EL3, when EL3 is using AArch32. Otherwise, as described in [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#), encoding is unallocated and:
 - UNDEFINED, for the registers accessed using CRn set to c12.
 - CONSTRAINED UNPREDICTABLE, for the register accessed using CRn values other than c12.
- d. Introduced in ARMv8.
- e. Introduced in ARMv8. Implemented only if the implementation includes the GIC System registers. For information see [Generic Interrupt Controller System registers, functional groups on page G4-4207](#). As that subsection describes, each ICV_* register uses the same encoding as the corresponding ICC_* register
- f. This register is only accessible in Debug state.
- g. When an implementation is using the Long descriptor translation table format these encodings access the [MAIR0](#) and [MAIR1](#) registers. Otherwise, they access the [PRRR](#) and [NMRR](#).

- h. Introduced in ARMv8. Only one of [RMR \(at EL1\)](#), [HRMR](#), and [RMR \(at EL3\)](#) is implemented, corresponding to the highest implemented Exception level, and the register is implemented only if that Exception level is using AArch32.
- i. Implemented as part of the Generic Timer.
- j. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see [Status of the CNTVOFF register on page G5-4223](#).

G4.16.3 AArch32 views of the System registers in the (coproc==0b1111) encoding space

The following sections summarize the different software views of the System registers in the (coproc==0b1111) encoding space, for VMSAv8-32:

- [PL0 views of the System registers in the \(coproc==0b1111\) encoding space.](#)
- [PL1 views of the System registers in the \(coproc==0b1111\) encoding space on page G4-4192.](#)
- [Non-secure PL2 view of the System registers in the \(coproc==0b1111\) encoding space on page G4-4192.](#)

———— **Note** ————

In previous versions of the ARM architecture, the behavior of accesses to the System registers in the (coproc==0b1111) encoding space were described in relation to the PE modes. In Secure state, the Exception level of the privileged PE modes depends on whether EL3 is using AArch32, or is using AArch64. This means it is simpler to describe the views of the registers in terms of *privilege levels*, PL0-PL2, rather than the *Exception levels* EL1-EL3. This is because each AArch32 PE mode is associated with a particular privilege level, but in Secure state its Exception level can depend on the EL3 Execution state. For more information see [Security state, Exception levels, and AArch32 execution privilege on page G1-3792.](#)

PL0 views of the System registers in the (coproc==0b1111) encoding space

Software executing at PL0, unprivileged, can access only a small subset of the System registers in the (coproc==0b1111) encoding space, as [Table G4-46](#) shows. This table excludes possible PL0 access to the following registers:

- The Performance Monitors Extension, see [Possible PL0 access to the Performance Monitors Extension System registers on page G4-4191.](#)
- The Generic Timer registers, see [Possible PL0 access to the Generic Timer System registers on page G4-4191.](#)

Table G4-46 System registers in the (coproc==0b1111) encoding space accessible from PL0

| Name | Access | Description | Note |
|----------|--------|--|--|
| CP15ISB | WO | Memory barriers on page E2-2335 | ARM deprecates use of these operations |
| CP15DSB | WO | | |
| CP15DMB | WO | | |
| TPIDRURW | RW | TPIDRURW, PL0 Read/Write Software Thread ID Register on page G6-4641 | - |
| TPIDRURO | RO | TPIDRURO, PL0 Read-Only Software Thread ID Register on page G6-4639 | RW at PL1 |

Possible PL0 access to the Performance Monitors Extension System registers

In a VMSAv8-32 implementation that includes the Performance Monitors Extension, when using the System register interface to the Performance Monitors:

- The [PMUSERENR](#) is RO from PL0.
- When:
 - The value of [PMUSERENR.EN](#) is 1, [PMCNTENSET](#), [PMCNTENCLR](#), [PMOVSr](#), [PMSWINC](#), [PMSELR](#), [PMCEID0](#), [PMCEID1](#), [PMCCNTR](#), [PMXEVTYPER](#), [PMXEVCNTR](#), [PMUSERENR](#), [PMOVSSET](#), [PMEVCNTR<n>](#), [PMEVTYPER<n>](#), and [PMCCFILTR](#) are accessible by reads and writes from PL0.
 - The value of [PMUSERENR.ER](#) is 1, [PMXEVCNTR](#) and [PMEVCNTR<n>](#) are accessible by reads and from PL0, and [PMSELR](#) is accessible by reads and writes from PL0.
 - The value of [PMUSERENR.CR](#) is 1, [PMCCNTR](#) is accessible by reads from PL0.
 - The value of [PMUSERENR.SW](#) is 1, [PMSWINC](#) is accessible by writes from PL0.

In general, when the value of a [PMUSERENR](#).{EN, ER, CR, SW} bit is 1, the enabled registers have the same access permissions from PL0 as they do from PL1.

For more information, see:

- [Traps to EL1 of EL0 accesses to Performance Monitors registers on page D1-1570](#).
- [Chapter D5 The Performance Monitors Extension](#), in particular [Access permissions on page D5-1871](#).

Possible PL0 access to the Generic Timer System registers

In a VMSAv8-32 implementation, when using the System register interface to the Generic Timer registers:

- If [CNTKCTL.PLOPCTEN](#) is set to 1, then if the physical counter register [CNTPCT](#) is accessible from PL1 it is also accessible from PL0. For more information see [Accessing the physical counter on page D6-1880](#).
- If [CNTKCTL.PLOPVTEN](#) is set to 1, the virtual counter register [CNTVCT](#) is accessible from PL0. For more information, see [Accessing the virtual counter on page D6-1881](#).
- If at least one of [CNTKCTL](#).{[PLOPCTEN](#), [PLOPVTEN](#)} is set to 1, the [CNTFRQ](#) register is RO from PL0.
- If:
 - [CNTKCTL.PLOPTEN](#) is set to 1, the physical timer registers [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) are accessible from PL0.
 - [CNTKCTL.PLOVTEN](#) is set to 1, the virtual timer registers [CNTV_CTL](#), [CNTV_CVAL](#), and [CNTV_TVAL](#), are accessible from PL0.

For more information, see [Accessing the timer registers on page D6-1883](#).

PL1 views of the System registers in the in the (coproc==0b1111) encoding space

Software executing at PL1 can access all System registers in the (coproc==0b1111) encoding space, with the following exceptions:

Non-secure PL1 software

EL3 restricts or prevents access to some registers by Non-secure PL1 software. In particular:

- The Restricted access System registers are either not accessible to Non-secure PL1 software, or are read-only to Non-secure PL1 software, see [Restricted access System registers on page G4-4156](#).
- Configuration settings determine whether Non-secure PL1 software can access the Configurable access System registers, see [Configurable access System registers on page G4-4157](#).

The individual register descriptions identify these access restrictions.

In an implementation that includes EL2, Non-secure PL1 software has no visibility of the PL2-mode registers summarized in [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space on page G4-4157](#). The individual register descriptions identify these registers as EL2-mode registers.

Secure PL1 software

In general, Secure PL1 software has access to all System registers. However:

- When EL3 is using AArch32, the **CP15SDISABLE** signal disables write access to a number of Secure registers, see [The CP15SDISABLE input signal on page G4-4161](#).
- The PL2-mode registers are accessible from Secure state only if EL3 is using AArch32. When this is the case, Secure PL1 software can access these registers by moving into Monitor mode, and setting **SCR.NS** to 1. [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space on page G4-4157](#) summarizes these registers.

The individual register descriptions identify:

- The registers affected by the **CP15SDISABLE** signal.
- The PL2-mode registers.

Non-secure PL2 view of the System registers in the (coproc==0b1111) encoding space

Non-secure software executing at PL2 can access:

- The registers that are accessible to Non-secure software executing at PL1, as defined in [PL1 views of the System registers in the in the \(coproc==0b1111\) encoding space](#). Access permissions for these registers are identical to those for Non-secure software executing at EL1.
- The PL2-mode registers summarized in [Hyp mode read/write registers in the \(coproc==0b1111\) encoding space on page G4-4157](#), and described in [Virtualization registers, functional group on page G4-4197](#).

G4.17 Functional grouping of VMSAv8-32 System registers

This section describes how the System registers in an VMSAv8-32 implementation divide into functional groups.

[General system control registers on page G6-4231](#) describes each of these registers.

———— Note ————

- [Table G4-45 on page G4-4179](#) lists all of the VMSAv8-32 System registers in the (coproc==0b1111) encoding space, ordered by:
 1. The CRn primary register used when using a 32-bit access to the register.
For 64-bit register accesses using an MCRR or MRRC instruction, the instruction arguments that identify the target register are {coproc, Rm, opc1}. The value of Rm determines where these registers appear in [Table G4-45 on page G4-4179](#), so that these registers appear with the 32-bit registers accessed using that value for CRn. So, for example, the 64-bit access to [TTBR0](#), that uses (CRm==c2), appears with the 32-bit access to [TTBR0](#), that uses (CRn==c2).
 2. The opc1 value used when accessing the register.
 3. For 32-bit registers, the {CRm, opc2} values used when accessing the register.
- The functional groups defined in this section mainly consist of the VMSAv8-32 System registers, but include some additional System registers.
- Some registers belong to more than one functional group.

For other related information see:

- [The AArch32 System register interface on page G1-3877](#) for general information about the access to the AArch32 System registers, including the main register access instructions MRC and MCR
- [About the System registers for VMSAv8-32 on page G4-4148](#) for general information about the System registers for VMSAv8-32, including:
 - Their organization, both by the {coproc, CRn, opc1, CRm, opc2} parameters and by function.
 - Their general behavior.
 - The effect of not implementing some Exception levels on the registers.
 - Different views of the registers, that depend on the state of the PE.
 - Conventions used in describing the registers.

The remainder of this chapter, and [General system control registers on page G6-4231](#), assumes you are familiar with [About the System registers for VMSAv8-32 on page G4-4148](#), and uses conventions and other information from that section without any explanation.

Each of the following sections summarizes a functional group of VMSAv8-32 System registers:

- [Identification registers, functional group on page G4-4194.](#)
- [General system control registers, functional group on page G4-4195.](#)
- [Virtual memory control registers, functional group on page G4-4196.](#)
- [Virtualization registers, functional group on page G4-4197.](#)

| TCMTR | c0 | 0 | c0 | 2 | 32-bit | RO | TCM Type Register |

Table G4-47 Identification registers, VMSAv8-32 (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|------------------------|-----|------|-----|------|--------|------|---|
| TLBTR | c0 | 0 | c0 | 3 | 32-bit | RO | TLB Type Register |
| VMPIDR | c0 | 4 | c0 | 5 | 32-bit | RW | Virtualization Multiprocessor ID Register |
| VPIDR | c0 | 4 | c0 | 5 | 32-bit | RW | Virtualization Processor ID Register |

a. CPUID register, see [The CPUID identification scheme](#).

The other registers in this group are the [FPSID](#), [MVFR0](#), [MVFR1](#), and [MVFR2](#).

The [JIDR](#) holds legacy identification information.

The CPUID identification scheme

The ID_* registers were originally called the CPUID identification scheme registers. A footnote to [Table G4-47 on page G4-4194](#) identifies these registers. However, functionally, there is no value in separating these registers from the slightly larger Identification registers functional group.

G4.17.2 General system control registers, functional group

[Table G4-48](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the General system control registers functional group.

Table G4-48 General system control registers, VMSAv8-32

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|-------------------------|-----|------|-----|------|--------|------|---|
| ACTLR | c1 | 0 | c0 | 1 | 32-bit | RW | Auxiliary Control Register |
| ACTLR2 | c1 | 0 | c0 | 3 | 32-bit | RW | Auxiliary Control Register 2 |
| CPACR | c1 | 0 | c0 | 2 | 32-bit | RW | Architectural Feature Access Control Register |
| HACTLR | c1 | 4 | c0 | 0 | 32-bit | RW | Hyp Auxiliary System Control Register |
| HACTLR2 | c1 | 4 | c0 | 3 | 32-bit | RW | Hyp Auxiliary System Control Register 2 |
| HSCTLR | c1 | 4 | c0 | 0 | 32-bit | RW | Hyp System Control Register |
| SCTLR | c1 | 0 | c0 | 0 | 32-bit | RW | System Control Register |

The following sections summarize the System registers added by the corresponding Exception levels:

- [Security registers, functional group on page G4-4199](#).
- [Virtualization registers, functional group on page G4-4197](#).

G4.17.3 Virtual memory control registers, functional group

Table G4-49 shows the VMSAv8-32 System registers in the (coproc == 0b1111) encoding space that are in the Virtual memory control registers functional group.

Table G4-49 Virtual memory control registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|------------|-----|------|-----|------|--------|------|---|
| AMAIRO | c10 | 0 | c3 | 0 | 32-bit | RW | Auxiliary Memory Attribute Indirection Register 0 |
| AMAIR1 | c10 | 0 | c3 | 1 | 32-bit | RW | Auxiliary Memory Attribute Indirection Register 1 |
| CONTEXTIDR | c13 | 0 | c0 | 1 | 32-bit | RW | Context ID Register |
| DACR | c3 | 0 | c0 | 0 | 32-bit | RW | Domain Access Control Register |
| HAMAIRO | c10 | 4 | c3 | 0 | 32-bit | RW | Hyp Auxiliary Memory Attribute Indirection Register 0 |
| HAMAIR1 | c10 | 4 | c3 | 1 | 32-bit | RW | Hyp Auxiliary Memory Attribute Indirection Register 1 |
| HMAIRO | c10 | 4 | c2 | 0 | 32-bit | RW | Hyp Memory Attribute Indirection Register 0 |
| HMAIR1 | c10 | 4 | c2 | 1 | 32-bit | RW | Hyp Memory Attribute Indirection Register 1 |
| HTCR | c2 | 4 | c0 | 2 | 32-bit | RW | Hyp Translation Control Register |
| HTTBR | - | 4 | c2 | - | 64-bit | RW | Hyp Translation Table Base Register |
| MAIRO | c10 | 0 | c2 | 0 | 32-bit | RW | Memory Attribute Indirection Register 0 |
| MAIR1 | c10 | 0 | c2 | 1 | 32-bit | RW | Memory Attribute Indirection Register 1 |
| NMRR | c10 | 0 | c2 | 1 | 32-bit | RW | Normal Memory Remap Register |
| PRRR | c10 | 0 | c2 | 0 | 32-bit | RW | Primary Region Remap Register |
| SCTLR | c1 | 0 | c0 | 0 | 32-bit | RW | System Control Register |
| TTBCR | c2 | 0 | c0 | 2 | 32-bit | RW | Translation Table Base Control Register |
| TTBR0 | c2 | 0 | c0 | 0 | 32-bit | RW | Translation Table Base Register 0 |
| TTBR0 | - | 0 | c2 | - | 64-bit | RW | Translation Table Base Register 0 |
| TTBR1 | c2 | 0 | c0 | 1 | 32-bit | RW | Translation Table Base Register 1 |
| TTBR1 | - | 1 | c2 | - | 64-bit | RW | Translation Table Base Register 1 |
| VTCCR | c2 | 4 | c1 | 2 | 32-bit | RW | Virtualization Translation Control Register |
| VTTBR | - | 6 | c2 | - | 64-bit | RW | Virtualization Translation Table Base Register |

The [ACTLR](#) and, if implemented, [ACTLR2](#), might provide additional virtual memory control.

G4.17.4 Virtualization registers, functional group

Table G4-50 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Virtualization registers functional group, excluding the System instructions in this group.

Table G4-50 Virtualization registers, excluding System instructions

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|------------|-----|------|-----|------|--------|------|---|
| CNTHCTL | c14 | 4 | c1 | 0 | 32-bit | RW | Counter-timer Hyp Control register |
| CNTHP_CTL | c14 | 4 | c2 | 1 | 32-bit | RW | Counter-timer Hyp Physical Timer Control register |

Table G4-50 Virtualization registers, excluding System instructions (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|----------------------------------|-----|------|-----|------|--------|------|---|
| ICC_HSRE ^a | c12 | 4 | c9 | 5 | 32-bit | RW | Interrupt Controller Hyp System Register Enable register |
| ICH_AP0R0 ^a | c12 | 4 | c8 | 0 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,0) |
| ICH_AP0R1 ^a | c12 | 4 | c8 | 1 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,1) |
| ICH_AP0R2 ^a | c12 | 4 | c8 | 2 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,2) |
| ICH_AP0R3 ^a | c12 | 4 | c8 | 3 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,3) |
| ICH_AP1R0 ^a | c12 | 4 | c9 | 0 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,0) |
| ICH_AP1R1 ^a | c12 | 4 | c9 | 1 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,1) |
| ICH_AP1R2 ^a | c12 | 4 | c9 | 2 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,2) |
| ICH_AP1R3 ^a | c12 | 4 | c9 | 3 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,3) |
| ICH_EISR ^a | c12 | 4 | c11 | 3 | 32-bit | RO | Interrupt Controller End of Interrupt Status Register |
| ICH_ELRSR ^a | c12 | 4 | c11 | 5 | 32-bit | RO | Interrupt Controller Empty List Register Status Register |
| ICH_HCR ^a | c12 | 4 | c11 | 0 | 32-bit | RW | Interrupt Controller Hyp Control Register |
| ICH_LR<n>, n==0-7 ^a | c12 | 4 | c12 | 0-7 | 32-bit | RW | Interrupt Controller List Registers, 0-7 |
| ICH_LR<n>, n==8-15 ^a | c12 | 4 | c13 | 0-7 | 32-bit | RW | Interrupt Controller List Registers, 8-15 |
| ICH_LRC<n>, n==0-7 ^a | c12 | 4 | c14 | 0-7 | 32-bit | RW | Interrupt Controller List Registers Continuation, 0-7 |
| ICH_LRC<n>, n==8-15 ^a | c12 | 4 | c15 | 0-7 | 32-bit | RW | Interrupt Controller List Registers Continuation, 8-15 |
| ICH_MISR ^a | c12 | 4 | c11 | 2 | 32-bit | RO | Interrupt Controller Maintenance Interrupt State Register |
| ICH_VMCR ^a | c12 | 4 | c11 | 7 | 32-bit | RW | Interrupt Controller Virtual Machine Control Register |
| ICH_VTR ^a | c12 | 4 | c11 | 1 | 32-bit | RO | Interrupt Controller VGIC Type Register |
| VMPIDR | c0 | 4 | c0 | 5 | 32-bit | RW | Virtualization Multiprocessor ID Register |
| VPIDR | c0 | 4 | c0 | 0 | 32-bit | RW | Virtualization Processor ID Register |
| VTCCR | c2 | 4 | c1 | 2 | 32-bit | RW | Virtualization Translation Control Register |
| VTTBR | - | 6 | c2 | - | 64-bit | RW | Virtualization Translation Table Base Register |

a. For more information about these registers see *Generic Interrupt Controller System registers, functional groups* on page G4-4207. As that section describes, each ICV_* register uses the same encoding as the corresponding ICC_* register.

Table G4-51 shows the Hyp mode System instructions, in the (coproc==0b1111) encoding space, that are part of this functional group. See also Table G4-50 on page G4-4197.

Table G4-51 Hyp mode System instructions

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|---|-----|------|-----|------|--------|------|--|
| ATS1HR | c7 | 4 | c8 | 0 | 32-bit | WO | Address Translate Stage 1 Hyp mode Read |
| ATS1HW | c7 | 4 | c8 | 1 | 32-bit | WO | Address Translate Stage 1 Hyp mode Write |
| TLBIALLH^a | c8 | 4 | c7 | 0 | 32-bit | WO | Invalidate entire Hyp unified TLB |
| TLBIALLHIS^a | c8 | 4 | c3 | 0 | 32-bit | WO | Invalidate entire Hyp unified TLB |
| TLBIALLNSNH^a | c8 | 4 | c7 | 4 | 32-bit | WO | Invalidate entire Non-secure Non-Hyp unified TLB |
| TLBIALLNSNHIS^a | c8 | 4 | c3 | 4 | 32-bit | WO | Invalidate entire Non-secure Non-Hyp unified TLB |
| TLBIIPAS2^a | c8 | 4 | c4 | 1 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2 |
| TLBIIPAS2IS^a | c8 | 4 | c0 | 1 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Inner Shareable |
| TLBIIPAS2L^a | c8 | 4 | c4 | 5 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Last level |
| TLBIIPAS2LIS^a | c8 | 4 | c0 | 5 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Last level, Inner Shareable |
| TLBIMVAH^a | c8 | 4 | c7 | 1 | 32-bit | WO | Invalidate Hyp unified TLB by VA |
| TLBIMVAHIS^a | c8 | 4 | c3 | 1 | 32-bit | WO | Invalidate Hyp unified TLB by VA |
| TLBIMVALH^a | c8 | 4 | c7 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level, Hyp mode |
| TLBIMVALHIS^a | c8 | 4 | c3 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable |

a. These links are to a summary of the operation, and [The scope of TLB maintenance instructions on page G4-4101](#) describes the operation.

All the encodings shown in [Table G4-50 on page G4-4197](#) and [Table G4-51](#) are unallocated and CONstrained UNpredictable on an implementation that does not include EL2, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#).

G4.17.5 Security registers, functional group

Table G4-52 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Security registers functional group.

Table G4-52 Security registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|---|-----|------|-----|------|--------|------|--|
| ICC_MCTLR^a | c12 | 6 | c12 | 4 | 32-bit | RW | Interrupt Controller Monitor Control Register |
| ICC_MGRPEN1^a | c12 | 6 | c12 | 7 | 32-bit | RW | Interrupt Controller Monitor Interrupt Group 1 Enable register |
| ICC_MSRE^a | c12 | 6 | c12 | 5 | 32-bit | RW | Interrupt Controller Monitor System Register Enable register |
| MVBAR | c12 | 0 | c0 | 1 | 32-bit | RW | Monitor Vector Base Address Register |

Table G4-52 Security registers (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|--------------|-----|------|-----|------|--------|------|------------------------------------|
| NSACR | c1 | 0 | c1 | 2 | 32-bit | RW | Non-Secure Access Control Register |
| RMR (at EL3) | c12 | 0 | c0 | 2 | 32-bit | RW | Reset Management Register |
| SCR | c1 | 0 | c1 | 0 | 32-bit | RW | Secure Configuration Register |
| SDER | c1 | 0 | c1 | 1 | 32-bit | RW | Secure Debug Enable Register |

a. For information about these registers see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

All the encodings shown in [Table G4-52 on page G4-4199](#) are unallocated and CONSTRAINED UNPREDICTABLE on an implementation that does not include EL3, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#).

G4.17.6 Exception and fault handling registers, functional group

[Table G4-53](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Exception and fault handling registers functional group.

Table G4-53 Exception and fault handling registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|--------|-----|------|-----|------|--------|------|---|
| ADFSR | c5 | 0 | c1 | 0 | 32-bit | RW | Auxiliary Data Fault Status Register |
| AIFSR | c5 | 0 | c1 | 1 | 32-bit | RW | Auxiliary Instruction Fault Status Register |
| DFAR | c6 | 0 | c0 | 0 | 32-bit | RW | Data Fault Address Register |
| DFSR | c5 | 0 | c0 | 0 | 32-bit | RW | Data Fault Status Register |
| HADFSR | c5 | 4 | c1 | 0 | 32-bit | RW | Hyp Auxiliary Data Fault Status Register |
| HAIFSR | c5 | 4 | c1 | 1 | 32-bit | RW | Hyp Auxiliary Instruction Fault Status Register |
| HDFAR | c6 | 4 | c0 | 0 | 32-bit | RW | Hyp Data Fault Address Register |
| HIFAR | c6 | 4 | c0 | 2 | 32-bit | RW | Hyp Instruction Fault Address Register |
| HPFAR | c6 | 4 | c0 | 4 | 32-bit | RW | Hyp IPA Fault Address Register |
| HSR | c5 | 4 | c2 | 0 | 32-bit | RW | Hyp Syndrome Register |
| HVBAR | c12 | 4 | c0 | 1 | 32-bit | RW | Hyp Vector Base Address Register |
| IFAR | c6 | 0 | c0 | 2 | 32-bit | RW | Instruction Fault Address Register |
| IFSR | c5 | 0 | c0 | 1 | 32-bit | RW | Instruction Fault Status Register |
| ISR | c12 | 0 | c1 | 0 | 32-bit | RO | Interrupt Status Register |
| MVBAR | c12 | 0 | c0 | 1 | 32-bit | RW | Monitor Vector Base Address Register |
| RVBAR | c12 | 0 | c0 | 1 | 32-bit | RW | Reset Vector Base Address Register |
| VBAR | c12 | 0 | c0 | 0 | 32-bit | RW | Vector Base Address Register |

The PE returns fault information using the fault status registers and the fault address registers. For details of how these registers are used see [Exception reporting in a VMSAv8-32 implementation on page G4-4123](#).

———— **Note** ————

These registers also report information about debug exceptions. For more information see:

- [Data Abort exceptions, taken to a PL1 mode on page G4-4125.](#)
- [Prefetch Abort exceptions, taken to a PL1 mode on page G4-4127.](#)
- [Reporting exceptions taken to Hyp mode on page G4-4133.](#)

G4.17.7 Reset management registers, functional group

[Table G4-54](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Reset management registers functional group.

Table G4-54 Reset management registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|------------------------------|-----|------|-----|------|--------|------|--------------------------------|
| HRMR | c12 | 4 | c0 | 2 | 32-bit | RW | Hyp Reset Management Register |
| RMR (at EL1) | c12 | 0 | c0 | 2 | 32-bit | RW | Reset Management Register, EL1 |
| RMR (at EL3) | c12 | 0 | c0 | 2 | 32-bit | RW | Reset Management Register, EL3 |

G4.17.8 Thread and process ID registers, functional group

[Table G4-55](#) shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Thread and process ID registers functional group.

Table G4-55 VMSAv8-32 Thread and process ID registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type ^a | Description |
|------------------------------------|-----|------|-----|------|--------|-------------------|--|
| HTPIDR^b | c13 | 4 | c0 | 2 | 32-bit | RW | Hyp Software Thread ID Register |
| TPIDRPRW | c13 | 0 | c0 | 4 | 32-bit | RW | PL1 Software Thread ID Register |
| TPIDRURO | c13 | 0 | c0 | 3 | 32-bit | RW, PL0 | PL0 Read-Only Software Thread ID Register |
| TPIDRURW | c13 | 0 | c0 | 2 | 32-bit | RW, PL0 | PL0 Read/Write Software Thread ID Register |

- PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- Implemented only as part of EL2. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151.](#)

G4.17.9 Cache maintenance instructions, functional group

[Table G4-56](#) shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the Cache and branch predictor maintenance instructions functional group.

Table G4-56 Cache and branch predictor maintenance instructions

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description | Limits ^a |
|--------------------------------------|-----|------|-----|------|--------|------|-----------------------------------|---------------------|
| BPIALL^b | c7 | 0 | c5 | 6 | 32-bit | WO | Branch predictor invalidate all | - |
| BPIALLIS^b | c7 | 0 | c1 | 6 | 32-bit | WO | Branch predictor invalidate all | IS |
| BPIMVA^b | c7 | 0 | c5 | 7 | 32-bit | WO | Branch predictor invalidate by VA | - |

Table G4-56 Cache and branch predictor maintenance instructions (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description | Limits ^a |
|---------------------------------------|-----|------|-----|------|--------|------|--|---------------------|
| DCCIMVAC^b | c7 | 0 | c14 | 1 | 32-bit | WO | Data cache clean and invalidate by VA | PoC |
| DCCISW^b | c7 | 0 | c14 | 2 | 32-bit | WO | Data cache clean and invalidate by set/way | - |
| DCCMVAC^b | c7 | 0 | c10 | 1 | 32-bit | WO | Data cache clean by VA | PoC |
| DCCMVAU^b | c7 | 0 | c11 | 1 | 32-bit | WO | Data cache clean by VA | PoU |
| DCCSW^b | c7 | 0 | c10 | 2 | 32-bit | WO | Data cache clean by set/way | - |
| DCIMVAC^b | c7 | 0 | c6 | 1 | 32-bit | WO | Data cache invalidate by VA | PoC |
| DCISW^b | c7 | 0 | c6 | 2 | 32-bit | WO | Data cache invalidate by set/way | - |
| ICIALLU^b | c7 | 0 | c5 | 0 | 32-bit | WO | Instruction cache invalidate all | PoU |
| ICIALLUIS^b | c7 | 0 | c1 | 0 | 32-bit | WO | Instruction cache invalidate all | PoU, IS |
| ICIMVAU^b | c7 | 0 | c5 | 1 | 32-bit | WO | Instruction cache invalidate by VA | PoU |

- a. PoU = to Point of Unification, PoC = to Point of Coherency, IS = Inner Shareable.
b. The links in this column are to a summary of the operation, see [AArch32 cache and branch predictor maintenance instructions on page G3-3999](#).

G4.17.10 TLB maintenance instructions, functional group

[Table G4-57](#) shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the TLB maintenance instructions functional group. [The scope of TLB maintenance instructions on page G4-4101](#) describes the operations.

Table G4-57 TLB maintenance instructions

| Name ^a | CRn | opc1 | CRm | opc2 | Width | Type | Description | Limits ^b |
|---------------------------------------|-----|------|-----|------|--------|------|--|---------------------|
| DTLBIALL^c | c8 | 0 | c6 | 0 | 32-bit | WO | Invalidate entire data TLB | - |
| DTLBIASID^c | c8 | 0 | c6 | 2 | 32-bit | WO | Invalidate data TLB by ASID | - |
| DTLBIMVA^c | c8 | 0 | c6 | 1 | 32-bit | WO | Invalidate data TLB entry by VA | - |
| ITLBIALL^c | c8 | 0 | c5 | 0 | 32-bit | WO | Invalidate entire instruction TLB | - |
| ITLBIASID^c | c8 | 0 | c5 | 2 | 32-bit | WO | Invalidate instruction TLB by ASID | - |
| ITLBIMVA^c | c8 | 0 | c5 | 1 | 32-bit | WO | Invalidate instruction TLB by VA | - |
| TLBIALL^d | c8 | 0 | c7 | 0 | 32-bit | WO | Invalidate entire unified TLB | - |
| TLBIALLH | c8 | 4 | c7 | 0 | 32-bit | WO | Invalidate entire Hyp unified TLB | - |
| TLBIALLHIS | c8 | 4 | c3 | 0 | 32-bit | WO | Invalidate entire Hyp unified TLB | IS |
| TLBIALLIS | c8 | 0 | c3 | 0 | 32-bit | WO | Invalidate entire unified TLB | IS |
| TLBIALLNSNH | c8 | 4 | c7 | 4 | 32-bit | WO | Invalidate entire Non-secure Non-Hyp unified TLB | - |
| TLBIALLNSNHIS | c8 | 4 | c3 | 4 | 32-bit | WO | Invalidate entire Non-secure Non-Hyp unified TLB | IS |

Table G4-57 TLB maintenance instructions (continued)

| Name ^a | CRn | opc1 | CRm | opc2 | Width | Type | Description | Limits ^b |
|------------------------------|-----|------|-----|------|--------|------|--|---------------------|
| TLBIASID | c8 | 0 | c7 | 2 | 32-bit | WO | Invalidate unified TLB by ASID | - |
| TLBIASIDIS | c8 | 0 | c3 | 2 | 32-bit | WO | Invalidate unified TLB by ASID | IS |
| TLBIIPAS2 | c8 | 4 | c4 | 1 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2 | - |
| TLBIIPAS2IS | c8 | 4 | c0 | 1 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Inner Shareable | IS |
| TLBIIPAS2L | c8 | 4 | c4 | 5 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Last level | - |
| TLBIIPAS2LIS | c8 | 4 | c0 | 5 | 32-bit | WO | TLB Invalidate entry by IPA, Stage 2, Last level, Inner Shareable | IS |
| TLBIMVAA | c8 | 0 | c7 | 3 | 32-bit | WO | Invalidate unified TLB by VA, all ASID | - |
| TLBIMVAAIS | c8 | 0 | c3 | 3 | 32-bit | WO | Invalidate unified TLB by VA, all ASID | IS |
| TLBIMVAAL | c8 | 0 | c7 | 7 | 32-bit | WO | TLB Invalidate entry by MVA, All ASID, Last level | - |
| TLBIMVAALIS | c8 | 0 | c3 | 7 | 32-bit | WO | TLB Invalidate entry by MVA, All ASID, Last level, Inner Shareable | IS |
| TLBIMVA | c8 | 0 | c7 | 1 | 32-bit | WO | Invalidate unified TLB by VA | - |
| TLBIMVAH | c8 | 4 | c7 | 1 | 32-bit | WO | Invalidate Hyp unified TLB by VA | - |
| TLBIMVAHIS | c8 | 4 | c3 | 1 | 32-bit | WO | Invalidate Hyp unified TLB by VA | IS |
| TLBIMVAIS | c8 | 0 | c3 | 1 | 32-bit | WO | Invalidate unified TLB by VA | IS |
| TLBIMVAL | c8 | 0 | c7 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level | - |
| TLBIMVALH | c8 | 4 | c7 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level, Hyp mode | - |
| TLBIMVALHIS | c8 | 4 | c3 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level, Hyp mode, Inner Shareable | IS |
| TLBIMVALIS | c8 | 0 | c3 | 5 | 32-bit | WO | TLB Invalidate entry by MVA, Last level | IS |

- a. These links are to a summary of the operation, and [The scope of TLB maintenance instructions on page G4-4101](#) describes the operation.
- b. IS = Inner Shareable.
- c. Deprecated. ARM deprecates use of operations that operate only on an Instruction TLB, or only on a Data TLB.
- d. The mnemonics for the operations with CRm==c7, opc2=={0, 1, 2} were previously UTLBIALL, UTLBIMVA and UTLBIMASID.

G4.17.11 Address translation instructions, functional group

Table G4-58 shows the VMSAv8-32 System instructions in the (coproc==0b1111) encoding space that are in the Address translation instructions functional group.

Table G4-58 Address translation instructions

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|--|-----|------|-----|------|--------|------|---|
| ATS12NSOPR ^{a, c} | c7 | 0 | c8 | 4 | 32-bit | WO | Stages 1 and 2 Non-secure only EL1 read |
| ATS12NSOPW ^{a, c} | c7 | 0 | c8 | 5 | 32-bit | WO | Stages 1 and 2 Non-secure only EL1 write |
| ATS12NSOUR ^{a, c} | c7 | 0 | c8 | 6 | 32-bit | WO | Stages 1 and 2 Non-secure only unprivileged read |
| ATS12NSOUW ^{a, c} | c7 | 0 | c8 | 7 | 32-bit | WO | Stages 1 and 2 Non-secure only unprivileged write |
| ATS1CPR ^c | c7 | 0 | c8 | 0 | 32-bit | WO | Stage 1 Current state EL1 read |
| ATS1CPW ^c | c7 | 0 | c8 | 1 | 32-bit | WO | Stage 1 Current state EL1 write |
| ATS1CUR ^c | c7 | 0 | c8 | 2 | 32-bit | WO | Stage 1 Current state unprivileged read |
| ATS1CUW ^c | c7 | 0 | c8 | 3 | 32-bit | WO | Stage 1 Current state unprivileged write |
| ATS1HR ^{b, c} | c7 | 4 | c8 | 0 | 32-bit | WO | Stage 1 Hyp mode read |
| ATS1HW ^{b, c} | c7 | 4 | c8 | 1 | 32-bit | WO | Stage 1 Hyp mode write |
| PAR | c7 | 0 | c4 | 0 | 32-bit | RW | Physical Address Register |
| | - | 0 | c7 | - | 64-bit | RW | |

- a. Implemented only as part of EL3. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#).
- b. Implemented only as part of EL2. Otherwise, encoding is unallocated and CONSTRAINED UNPREDICTABLE, see [Accesses to unallocated encodings in the \(coproc==0b111x\) encoding space on page G4-4151](#).
- c. These links are to a summary of the operation.

[Address translation instructions on page G4-4142](#) describes these operations.

G4.17.12 Lockdown, DMA, and TCM features, functional group

Table G4-59 shows the VMSAv8-32 reserved encodings in the (coproc==0b1111) encoding space that provide the Lockdown, DMA, and TCM features registers functional group.

Table G4-59 Lockdown, DMA, and TCM features, VMSAv8-32

| Name | CRn | opc1 | CRm | Width | opc2 | Type | Description |
|------------------------|-----|------|-------|--------|------|------|--|
| IMPLEMENTATION DEFINED | c9 | 0-7 | c0-c2 | 32-bit | 0-7 | a | Reserved for IMPLEMENTATION DEFINED branch predictor, cache, and TCM operations. |
| | | | c5-c8 | 32-bit | 0-7 | a | |
| | c10 | 0-7 | c0-c1 | 32-bit | 0-7 | a | Reserved for IMPLEMENTATION DEFINED TLB lockdown operations |
| | | | c4 | 32-bit | 0-7 | a | |
| | | | c8 | 32-bit | 0-7 | a | |
| | c11 | 0-7 | c0-c8 | 32-bit | 0-7 | a | Reserved for IMPLEMENTATION DEFINED DMA operations to and from TCMs |
| | | | c15 | 32-bit | 0-7 | a | |

a. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.17.13 Performance Monitors Extension registers, functional group

Table G4-60 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are the Performance Monitors Extension registers functional group. See also *IMPLEMENTATION DEFINED performance monitors* on page G4-4206.

Table G4-60 Performance Monitors Extension registers

| Name | CRn | opc1 | CRm | opc2 | Width | Description |
|------------------------------|-----|------|-----|------|--------|---|
| PMCCFILTR | c14 | 0 | c15 | 7 | 32-bit | Performance Monitors Cycle Count Filter Register |
| PMCCNTR | c9 | 0 | c13 | 0 | 32-bit | Performance Monitors Cycle Count Register |
| PMCEID0 | c9 | 0 | c12 | 6 | 32-bit | Performance Monitors Common Event Identification register 0 |
| PMCEID1 | c9 | 0 | c12 | 7 | 32-bit | Performance Monitors Common Event Identification register 1 |
| PMCNTENCLR | c9 | 0 | c12 | 2 | 32-bit | Performance Monitors Count Enable Clear register |
| PMCNTENSET | c9 | 0 | c12 | 1 | 32-bit | Performance Monitors Count Enable Set register |
| PMCR | c9 | 0 | c12 | 0 | 32-bit | Performance Monitors Control Register |
| PMEVCNTR<n>, for n==0 to 7 | c14 | 0 | c8 | 0-7 | 32-bit | Performance Monitors Event Count Registers, 0-7 |
| PMEVCNTR<n>, for n==16 to 23 | c14 | 0 | c10 | 0-7 | 32-bit | Performance Monitors Event Count Registers, 16-23 |
| PMEVCNTR<n>, for n==24 to 30 | c14 | 0 | c11 | 0-6 | 32-bit | Performance Monitors Event Count Registers, 24-30 |
| PMEVCNTR<n>, for n==8 to 15 | c14 | 0 | c9 | 0-7 | 32-bit | Performance Monitors Event Count Registers, 8-15 |

Table G4-60 Performance Monitors Extension registers (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Description |
|--|-----|------|-----|------|--------|--|
| PMEVTYPER<n> , for n==0 to 7 | c14 | 0 | c12 | 0-7 | 32-bit | Performance Monitors Event Type Registers, 0-7 |
| PMEVTYPER<n> , for n== 16 to 23 | c14 | 0 | c14 | 0-7 | 32-bit | Performance Monitors Event Type Registers, 16-23 |
| PMEVTYPER<n> , for n== 17 to 30 | c14 | 0 | c15 | 0-6 | 32-bit | Performance Monitors Event Type Registers, 24-30 |
| PMEVTYPER<n> , for n==8 to 15 | c14 | 0 | c13 | 0-7 | 32-bit | Performance Monitors Event Type Registers, 8-15 |
| PMINTENCLR | c9 | 0 | c14 | 2 | 32-bit | Performance Monitors Interrupt Enable Clear register |
| PMINTENSET | c9 | 0 | c14 | 1 | 32-bit | Performance Monitors Interrupt Enable Set register |
| PMOVSRR | c9 | 0 | c12 | 3 | 32-bit | Performance Monitors Overflow Flag Status Register |
| PMOVSSET | c9 | 0 | c14 | 3 | 32-bit | Performance Monitors Overflow Flag Status Set register |
| PMSCLR | c9 | 0 | c12 | 5 | 32-bit | Performance Monitors Event Counter Selection Register |
| PMSWINC | c9 | 0 | c12 | 4 | 32-bit | Performance Monitors Software Increment register |
| PMUSERENR | c9 | 0 | c14 | 0 | 32-bit | Performance Monitors User Enable Register |
| PMXEVCNTR | c9 | 0 | c13 | 2 | 32-bit | Performance Monitors Event Count Register |
| PMXEVTYPER | c9 | 0 | c13 | 1 | 32-bit | Performance Monitors Event Type Select Register |

IMPLEMENTATION DEFINED performance monitors

VMSAv8-32 reserves some additional System register encodings in the (coproc==0b1111) encoding space for optional additional IMPLEMENTATION DEFINED performance monitors. [Table G4-61](#) shows the allocation of these encodings:

Table G4-61 Performance Monitors System register encoding allocations

| CRn | opc1 | CRm | opc2 | Name | Width | Type |
|-----|------|---------|------|---|--------|-----------------------|
| c9 | 0-7 | c12-c14 | 0-7 | Performance Monitors Extension registers, see Table G4-60 on page G4-4205 | 32-bit | RW or RO ^a |
| | | c15 | 0-7 | IMPLEMENTATION DEFINED | 32-bit | b |

a. The table referenced in the *Name* entry shows the type of each of the OPTIONAL Performance Monitors Extension registers.

b. Access depends on the register or operation, and is IMPLEMENTATION DEFINED.

G4.17.14 Generic Timer registers, functional group

Table G4-62 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are the Generic Timer registers functional group.

Table G4-62 Generic Timer registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type ^a | Description |
|----------------------|-----|------|-----|------|--------|-------------------|--|
| CNTRQ | c14 | 0 | c0 | 0 | 32-bit | RW | Counter Frequency register |
| CNTHCTL | c14 | 4 | c1 | 0 | 32-bit | RW | Timer EL2 Control register |
| CNTHP_CTL | c14 | 4 | c2 | 1 | 32-bit | RW | EL2 Physical Timer Control register |
| CNTHP_CVAL | - | 6 | c14 | - | 64-bit | RW | EL2 Physical Timer CompareValue register |
| CNTHP_TVAL | c14 | 4 | c2 | 0 | 32-bit | RW | EL2 Physical TimerValue register |
| CNTKCTL | c14 | 0 | c1 | 0 | 32-bit | RW | Timer EL1 Control register |
| CNTP_CTL | c14 | 0 | c2 | 1 | 32-bit | RW | EL1 Physical Timer Control register |
| CNTP_CVAL | - | 2 | c14 | - | 64-bit | RW | EL1 Physical Timer CompareValue register |
| CNTP_TVAL | c14 | 0 | c2 | 0 | 32-bit | RW | EL1 Physical TimerValue register |
| CNTPCT | - | 0 | c14 | - | 64-bit | RW | Physical Count register |
| CNTV_CTL | c14 | 0 | c3 | 1 | 32-bit | RW | Virtual Timer Control register |
| CNTV_CVAL | - | 3 | c14 | - | 64-bit | RW | Virtual Timer CompareValue register |
| CNTV_TVAL | c14 | 0 | c3 | 0 | 32-bit | RW | Virtual TimerValue register |
| CNTVCT | - | 1 | c14 | - | 64-bit | RO | Virtual Count register |
| CNTVOFF ^b | - | 4 | c14 | - | 64-bit | RW | Virtual Offset register |

a. See the register descriptions for more information. Accessibility can depend on configuration settings as well as on the current Exception level.

b. Implemented as RW as part of the Generic Timer on an implementation that includes EL2 and when EL2 is using AArch32. For more information see *Status of the CNTVOFF register* on page G5-4223.

G4.17.15 Generic Interrupt Controller System registers, functional groups

From version 3.0 of the GIC architecture specification, the specification defines three groups of System registers, identified by the prefix of the register name:

ICC_ GIC physical CPU interface System registers.

ICH_ GIC virtual interface control System registers.

ICV_ GIC Virtual CPU interface System registers.

———— **Note** —————

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

In VMSAv8-32, the GIC System registers are all in the (coproc==0b1111) encoding space with (CRn==c12). The ICV_* registers have the same {CRn, opc1, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information see the *ARM® Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0 and version 4.0* (ARM IHI 0069).

Table G4-63 shows the functional groups of GIC System registers.

Table G4-63 Generic Interrupt Controller System registers

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|--|-----|------|-----|------|--------|------|--|
| ICC_AP0R0 ^a ICV_AP0R0 ^a | c12 | 0 | c8 | 4 | 32-bit | RW | Interrupt Controller Active Priorities Register (0,0) Interrupt Controller Virtual Active Priorities Register (0,0) |
| ICC_AP0R1 ^a ICV_AP0R1 ^a | c12 | 0 | c8 | 5 | 32-bit | RW | Interrupt Controller Active Priorities Register (0,1) Interrupt Controller Virtual Active Priorities Register (0,1) |
| ICC_AP0R2 ^a ICV_AP0R2 ^a | c12 | 0 | c8 | 6 | 32-bit | RW | Interrupt Controller Active Priorities Register (0,2) Interrupt Controller Virtual Active Priorities Register (0,2) |
| ICC_AP0R3 ^a ICV_AP0R3 ^a | c12 | 0 | c8 | 7 | 32-bit | RW | Interrupt Controller Active Priorities Register (0,3) Interrupt Controller Virtual Active Priorities Register (0,3) |
| ICC_APIR0 ^a ICV_APIR0 ^a | c12 | 0 | c9 | 0 | 32-bit | RW | Interrupt Controller Active Priorities Register (1,0) Interrupt Controller Virtual Active Priorities Register (1,0) |
| ICC_APIR1 ^a ICV_APIR1 ^a | c12 | 0 | c9 | 1 | 32-bit | RW | Interrupt Controller Active Priorities Register (1,1) Interrupt Controller Virtual Active Priorities Register (1,1) |
| ICC_APIR2 ^a ICV_APIR2 ^a | c12 | 0 | c9 | 2 | 32-bit | RW | Interrupt Controller Active Priorities Register (1,2) Interrupt Controller Virtual Active Priorities Register (1,2) |
| ICC_APIR3 ^a ICV_APIR3 ^a | c12 | 0 | c9 | 3 | 32-bit | RW | Interrupt Controller Active Priorities Register (1,3) Interrupt Controller Virtual Active Priorities Register (1,3) |
| ICC_ASGIIR | - | 1 | c12 | - | 64-bit | WO | Interrupt Controller Alias Software Generated Interrupt group 1 Register |
| ICC_BPR0 ^a ICV_BPR0 ^a | c12 | 0 | c8 | 3 | 32-bit | RW | Interrupt Controller Binary Point Register 0 Interrupt Controller Virtual Binary Point Register 0 |
| ICC_BPR1 ^a ICV_BPR1 ^a | c12 | 0 | c12 | 3 | 32-bit | RW | Interrupt Controller Binary Point Register 1 Interrupt Controller Virtual Binary Point Register 1 |
| ICC_CTLR ^a ICV_CTLR ^a | c12 | 0 | c12 | 4 | 32-bit | RW | Interrupt Controller Control Register Interrupt Controller Virtual Control Register |
| ICC_DIR ^a ICV_DIR ^a | c12 | 0 | c11 | 1 | 32-bit | WO | Interrupt Controller Deactivate Interrupt Register Interrupt Controller Deactivate Virtual Interrupt Register |
| ICC_EOIR0 ^a ICV_EOIR0 ^a | c12 | 0 | c8 | 1 | 32-bit | WO | Interrupt Controller End Of Interrupt Register 0 Interrupt Controller Virtual End Of Interrupt Register 0 |

Table G4-63 Generic Interrupt Controller System registers (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|--|-----|------|-----|------|--------|------|--|
| ICC_EOIR1 ^a ICV_EOIR1 ^a | c12 | 0 | c12 | 1 | 32-bit | WO | Interrupt Controller End Of Interrupt Register 1 Interrupt Controller Virtual End Of Interrupt Register 1 |
| ICC_HPPIR0 ^a ICV_HPPIR0 ^a | c12 | 0 | c8 | 2 | 32-bit | RO | Interrupt Controller Highest Priority Pending Interrupt Register 0 Interrupt Controller Virtual Highest Priority Pending Interrupt Register 0 |
| ICC_HPPIR1 ^a ICV_HPPIR1 ^a | c12 | 0 | c12 | 2 | 32-bit | RO | Interrupt Controller Highest Priority Pending Interrupt Register 1 Interrupt Controller Virtual Highest Priority Pending Interrupt Register 1 |
| ICC_HSRE | c12 | 4 | c9 | 5 | 32-bit | RW | Interrupt Controller Hyp System Register Enable register |
| ICC_IAR0 ^a ICV_IAR0 ^a | c12 | 0 | c8 | 0 | 32-bit | RO | Interrupt Controller Interrupt Acknowledge Register 0 Interrupt Controller Virtual Interrupt Acknowledge Register 0 |

| ICC_SGIOR | - | 2 | c12 | - | 64-bit | WO | Interrupt Controller Software Generated Interrupt group 0 Register |
| ICC_SGIIR | - | 0 | c12 | - | 64-bit | WO | Interrupt Controller Software Generated Interrupt group 1 Register |
| ICC_SRE | c12 | 0 | c12 | 5 | 32-bit | RW | Interrupt Controller System Register Enable register |

Table G4-63 Generic Interrupt Controller System registers (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|---------------------|-----|------|-----|------|--------|------|---|
| ICH_AP0R0 | c12 | 4 | c8 | 0 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,0) |
| ICH_AP0R1 | c12 | 4 | c8 | 1 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,1) |
| ICH_AP0R2 | c12 | 4 | c8 | 2 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,2) |
| ICH_AP0R3 | c12 | 4 | c8 | 3 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (0,3) |
| ICH_AP1R0 | c12 | 4 | c9 | 0 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,0) |
| ICH_AP1R1 | c12 | 4 | c9 | 1 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,1) |
| ICH_AP1R2 | c12 | 4 | c9 | 2 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,2) |
| ICH_AP1R3 | c12 | 4 | c9 | 3 | 32-bit | RW | Interrupt Controller Hyp Active Priorities Register (1,3) |
| ICH_EISR | c12 | 4 | c11 | 3 | 32-bit | RO | Interrupt Controller End of Interrupt Status Register |
| ICH_ELRSR | c12 | 4 | c11 | 5 | 32-bit | RO | Interrupt Controller Empty List Register Status Register |
| ICH_HCR | c12 | 4 | c11 | 0 | 32-bit | RW | Interrupt Controller Hyp Control Register |
| ICH_LR<n>, n==0-7 | c12 | 4 | c12 | 0-7 | 32-bit | RW | Interrupt Controller List Registers, 0-7 |
| ICH_LR<n>, n==8-15 | c12 | 4 | c13 | 0-7 | 32-bit | RW | Interrupt Controller List Registers, 8-15 |
| ICH_LRC<n>, n==0-7 | c12 | 4 | c14 | 0-7 | 32-bit | RW | Interrupt Controller List Registers Continuation, 0-7 |
| ICH_LRC<n>, n==8-15 | c12 | 4 | c15 | 0-7 | 32-bit | RW | Interrupt Controller List Registers Continuation, 8-15 |
| ICH_MISR | c12 | 4 | c11 | 2 | 32-bit | RO | Interrupt Controller Maintenance Interrupt State Register |
| ICH_VMCR | c12 | 4 | c11 | 7 | 32-bit | RW | Interrupt Controller Virtual Machine Control Register |
| ICH_VTR | c12 | 4 | c11 | 1 | 32-bit | RO | Interrupt Controller VGIC Type Register |

a. As described in this section, these ICC_* and ICV_* registers use the same encodings.

G4.17.16 Legacy feature registers, functional group

Table G4-64 shows the VMSAv8-32 System registers in the (coproc==0b1111) encoding space that are in the Legacy features registers functional group.

Table G4-64 Legacy features System registers in the (coproc==0b1111) encoding space

| Name | CRn | opc1 | CRm | opc2 | Width | Type ^a | Description |
|---------|-----|------|-----|------|--------|-------------------|---|
| CP15DMB | c7 | 0 | c10 | 5 | 32-bit | WO, PL0 | Memory barriers on page E2-2335 |
| CP15DSB | c7 | 0 | c10 | 4 | 32-bit | WO, PL0 | |
| CP15ISB | c7 | 0 | c5 | 4 | 32-bit | WO, PL0 | |
| FCSEIDR | c13 | 0 | c0 | 0 | 32-bit | RW ^b | FCSE Process ID Register |

- PL0 in a Type description indicates that the encoding is accessible by software executing at PL0. See the register description for more information.
- In ARMv8, the PE does not implement the [FCSEIDR](#), and therefore the register is RAZ/WI. See the register description for more information.

Table G4-65 shows the VMSAv8-32 System registers in the (coproc==0b1110) encoding space that are in the Legacy features registers functional group.

Table G4-65 Legacy features registers in the (coproc==0b1110) encoding space

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|-------|-----|------|-----|------|--------|------|-------------------------------------|
| JIDR | c0 | 7 | c0 | 0 | 32-bit | RO | Jazelle ID Register |
| JMCR | c2 | 7 | c0 | 0 | 32-bit | RW | Jazelle Main Configuration Register |
| JOSCR | c1 | 7 | c0 | 0 | 32-bit | RW | Jazelle OS Control Register |

G4.17.17 IMPLEMENTATION DEFINED registers, functional group

VMSAv8-32 defines some encodings for registers with content that is entirely IMPLEMENTATION DEFINED.

Table G4-66 shows these registers in the (coproc==0b1111) encoding space.

Table G4-66 Architectural encodings for registers with IMPLEMENTATION DEFINED content

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|---------|-----|------|-----|------|--------|------|---|
| ACTLR | c1 | 0 | c0 | 1 | 32-bit | RW | Auxiliary Control Register |
| ACTLR2 | c1 | 0 | c0 | 3 | 32-bit | RW | Auxiliary Control Register 2 |
| ADFSR | c5 | 0 | c1 | 0 | 32-bit | RW | Auxiliary Data Fault Status Register |
| AIDR | c0 | 1 | c0 | 7 | 32-bit | RO | Auxiliary ID Register |
| AIFSR | c5 | 0 | c1 | 1 | 32-bit | RW | Auxiliary Instruction Fault Status Register |
| AMAIRO | c10 | 0 | c3 | 0 | 32-bit | RW | Auxiliary Memory Attribute Indirection Register 0 |
| AMAIR1 | c10 | 0 | c3 | 1 | 32-bit | RW | Auxiliary Memory Attribute Indirection Register 1 |
| HACR | c1 | 4 | c1 | 7 | 32-bit | RW | Hyp Auxiliary Configuration Register |
| HACTLR | c1 | 4 | c0 | 0 | 32-bit | RW | Hyp Auxiliary System Control Register |
| HACTLR2 | c1 | 4 | c0 | 3 | 32-bit | RW | Hyp Auxiliary System Control Register 2 |

Table G4-66 Architectural encodings for registers with IMPLEMENTATION DEFINED content (continued)

| Name | CRn | opc1 | CRm | opc2 | Width | Type | Description |
|-------------------------|-----|------|-----|------|--------|------|---|
| HADFSR | c5 | 4 | c1 | 0 | 32-bit | RW | Hyp Auxiliary Data Fault Status Register |
| HAIFSR | c5 | 4 | c1 | 1 | 32-bit | RW | Hyp Auxiliary Instruction Fault Status Register |
| HAMAIRO | c10 | 4 | c3 | 0 | 32-bit | RW | Hyp Auxiliary Memory Attribute Indirection Register 0 |
| HAMAIR1 | c10 | 4 | c3 | 1 | 32-bit | RW | Hyp Auxiliary Memory Attribute Indirection Register 1 |
| REVIDR | c0 | 0 | c0 | 6 | 32-bit | RO | Revision ID Register |
| TCMTR | c0 | 0 | c0 | 2 | 32-bit | RO | TCM Type Register |

See also *IMPLEMENTATION DEFINED performance monitors* on page G4-4206.

G4.17.18 Advanced SIMD and floating-point registers, functional group

Table G4-67 shows the VMSAv8-32 System registers in the Advanced SIMD and floating-point registers functional group. These registers are accessed using VMRS and VMSR instructions, see the register descriptions for more information.

Table G4-67 Floating-point registers

| Name | Width | Type | Description |
|-----------------------|--------|-----------------|--|
| FPEXC | 32-bit | RW | Floating-Point Exception Control register |
| FPSCR | 32-bit | RW | Floating-Point Status and Control Register |
| FPSID | 32-bit | RW ^a | Floating-Point System ID register |
| MVFR0 | 32-bit | RO | Media and VFP Feature Register 0 |
| MVFR1 | 32-bit | RO | Media and VFP Feature Register 1 |
| MVFR2 | 32-bit | RO | Media and VFP Feature Register 2 |

a. When the [FPSID](#) is accessible, VMSR accesses to the [FPSID](#) are ignored.

G4.17.19 Debug registers, functional group

In AArch32 state, most Debug registers that are accessible through the System registers interface use {coproc==0b1110, opc1==0} encodings. Table G4-68 shows these registers.

Table G4-68 System register {coproc == 0b1110, opc1 == 0} encodings of Debug registers

| Name | CRn | opc2 | CRm | Width | Type | Description |
|----------------------------------|-----|------|--------|--------|------|---------------------------|
| DBGAUTHSTATUS | c7 | 6 | c14 | 32-bit | RO | Authentication Status |
| DBGBCR<n> | c0 | 5 | c0-c15 | 32-bit | RW | Breakpoint Control |
| DBGBVR<n> | c0 | 4 | c0-c15 | 32-bit | RW | Breakpoint Value |
| DBGBXVR<n> | c1 | 1 | c0-c15 | 32-bit | RW | Breakpoint Extended Value |
| DBGCLAIMCLR | c7 | 6 | c9 | 32-bit | RW | CLAIM Tag Clear |
| DBGCLAIMSET | c7 | 6 | c8 | 32-bit | RW | CLAIM Tag Set |

Table G4-68 System register {coproc == 0b1110, opc1 == 0} encodings of Debug registers (continued)

| Name | CRn | opc2 | CRm | Width | Type | Description |
|------------|-----|------|--------|--------|---------|--|
| DBGDCCINT | c0 | 0 | c2 | 32-bit | RW | Debug Communications Channel Interrupt Enable Register |

G4.18 Pseudocode description of VMSAv8-32 memory system operations

This section contains a list of pseudocode functions describing VMSAv8-32 memory operations. The following subsections describe the pseudocode functions:

- [Alignment fault.](#)
- [Address translation.](#)
- [Domain checking.](#)
- [TLB operations.](#)
- [Translation table walk.](#)
- [Reporting syndrome information on page G4-4216.](#)
- [Memory access decode when TEX remap is enabled on page G4-4216.](#)

See also the descriptions of pseudocode for general memory system operations in [Pseudocode description of general memory system instructions on page G3-4017.](#)

G4.18.1 Alignment fault

The `AArch32.AlignmentFault()` pseudocode function describes the generation of an Alignment fault Data Abort exception.

See also [Abort exceptions on page G3-4019.](#)

G4.18.2 Address translation

The `AArch32.TranslateAddress()` and `AArch32.FullTranslate()` pseudocode functions describe a VMSAv8-32 address translation.

The `AArch32.FullTranslate()` function calls either:

- The function described in [Address translation when the stage 1 address translation is disabled.](#)
- One of the functions described in [Translation table walk.](#)

[Stage 2 translation table walk on page G4-4216](#) describes the `CheckS2Permission()` and `CombineS1S2Desc()` pseudocode functions.

Address translation when the stage 1 address translation is disabled

The `AArch32.TranslateAddressS10ff()` pseudocode function describes the address translation performed when the stage 1 address translation is disabled.

G4.18.3 Domain checking

The `AArch32.CheckDomain()` pseudocode function describes domain checking.

G4.18.4 TLB operations

The `TLBRecord` type represents the contents of a TLB entry:

G4.18.5 Translation table walk

Because of the complexity of a translation table walk, the following sections describe the different cases:

- [Translation table walk using the Short-descriptor translation table format for stage 1 on page G4-4216.](#)
- [Translation table walk using the Long-descriptor translation table format for stage 1 on page G4-4216.](#)
- [Stage 2 translation table walk on page G4-4216.](#)

Translation table walk using the Short-descriptor translation table format for stage 1

The `AArch32.TranslationTableWalkSD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Short-descriptor format. It calls the function described in *Stage 2 translation table walk* if necessary.

The `ShortConvertAttrHints()` pseudocode function converts the Normal memory cacheability attribute, from the `TTBR` or the translation table `TEX` field, into the separate cacheability attribute and cache allocation hint defined in a Long-descriptor translation table descriptor.

Translation table walk using the Long-descriptor translation table format for stage 1

The `AArch32.TranslationTableWalkLD()` pseudocode function describes the translation table walk when the stage 1 translation tables use the Long-descriptor format. It calls the function described in *Stage 2 translation table walk* if necessary.

`AArch32.TranslationTableWalkLD()` calls the `ConvertAttrHints()` pseudocode function that is defined in *Translation table walk using the Short-descriptor translation table format for stage 1*.

The `AArch32.S1AttrDecode()` pseudocode function uses the `MAIRO` and `MAIR1` registers to decode the `Attr[2:0]` value from a stage 1 translation table descriptor.

The `S2AttrDecode()` pseudocode function decodes the `Attr[3:0]` value from a stage 2 translation table descriptor.

Stage 2 translation table walk

In the Non-secure EL1&0 translation regime, a descriptor address returned by stage 1 lookup is in the IPA address space, and must be mapped to a PA by a stage 2 translation. When EL2 is using AArch32, function `AArch32.SecondStageWalk()` performs this translation, by calling the `AArch32.SecondStageTranslate()` function. When called from `AArch32.SecondStageWalk()`, the `AArch32.SecondStageTranslate()` function performs a second stage translation, from IPA to PA, of the supplied address, including checking that the access has read permission at the second stage. If the access does not have second stage read permission it generates a second stage Permission fault on the first stage translation table walk. The second stage translation might hit in a TLB, or might involve a translation table walk, which will use the algorithm described in this section. Stage 2 translations tables always use the Long-descriptor translation table format.

The `AArch32.CheckPermission()` pseudocode function checks the access permissions for the stage 1 translation.

The `AArch32.CheckS2Permission()` pseudocode function checks the access permissions for the stage 2 translation.

The `CombineS1S2Desc()` pseudocode function combines the stage 1 and stage 2 access descriptors:

G4.18.6 Reporting syndrome information

The `AArch32.ReportHypEntry()`, `AArch32.ReportDataAbort()`, and `AArch32.ReportPrefetchAbort()` pseudocode functions write syndrome value information to the appropriate registers for the current mode.

G4.18.7 Memory access decode when TEX remap is enabled

When using the Short-descriptor translation table format, the function `AArch32.RemappedTEXDecode()` decodes the `texcb` and `S` attributes derived from the translation tables when TEX remap is enabled. *Short-descriptor format memory region attributes, with TEX remap on page G4-4080* shows the interpretation of the arguments.

Chapter G5

The Generic Timer in AArch32 state

This chapter describes the implementation of the ARM Generic Timer as an extension to an ARMv8 implementation. It includes an overview of the AArch32 System register interface to an ARM Generic Timer.

It contains the following sections:

- [About the Generic Timer in AArch32 state on page G5-4218.](#)
- [The AArch32 view of the Generic Timer on page G5-4222.](#)

[Chapter D6 The Generic Timer in AArch64 state](#) describes the AArch64 view of the Generic Timer, including an additional timer that can be implemented in AArch64 state, and [Chapter I1 System Level Implementation of the Generic Timer](#) describes the system level implementation of the Generic Timer.

G5.1 About the Generic Timer in AArch32 state

Figure G5-1 shows an example system-on-chip that uses the Generic Timer as a system timer. In this figure:

- This manual defines the architecture of the individual PEs in the multiprocessor blocks.
- The *ARM Generic Interrupt Controller Architecture Specification* defines a possible architecture for the interrupt controllers.
- Generic Timer functionality is distributed across multiple components.

Figure G5-1 Generic Timer example

The Generic Timer:

- Provides a system counter, that measures the passing of time in real-time.

———— **Note** ————

The Generic Timer can also provide other components at a system level, but Figure G5-1 does not show any such components.

- Supports *virtual counters* that measure the passing of virtual-time. That is, a virtual counter can measure the passing of time on a particular virtual machine.
- Timers, that can trigger events after a period of time has passed. The timers:
 - Can be used as count-up or as count-down timers.
 - Can operate in real-time or in virtual-time.

This chapter describes an instance of the Generic Timer component that Figure G5-1 shows as Timer_0 or Timer_1 within the Multiprocessor A or Multiprocessor B block. This component can be accessed from AArch64 state or AArch32 state, and this chapter describes access from AArch32 state. Chapter D6 *The Generic Timer in AArch64 state* describes access to this component from AArch64 state.

———— **Note** ————

The reset requirements of Generic Timer registers are more strict when they are accessed from AArch32 state than when they are accessed from AArch64 state.

A Generic Timer implementation must also include a memory-mapped system component, see [The full set of Generic Timer components](#).

G5.1.1 The full set of Generic Timer components

Within a system that might include multiple PEs, a full set of Generic Timer components is as follows:

The system counter

This provides a uniform view of system time, see [The system counter on page G5-4220](#). Because this must be implemented at the system level, it is accessed through [The system level memory-mapped implementation of the Generic Timer](#). However, during initialization, a status register in each implemented timer in the system must be programmed with the frequency of the system counter, so that software can read this frequency.

PE implementations of the Generic Timer

Each PE implementation of the Generic Timer provides the following components:

- A physical counter, that gives access to the count value of the system counter.
- A virtual counter, that gives access to virtual time. In AArch32 state, the [CNTVOFF](#) register defines the offset between physical time, as defined by the value of the system counter, and virtual time.
- A number of timers. In an implementation where all Exception levels are implemented and can use AArch32 state, the timers that are accessible from AArch64 state are:
 - A Secure PL1 physical timer.
 - A Non-secure EL1 physical timer.
 - An EL2 physical timer.
 - A virtual timer.

Note

The Secure PL1 physical timer uses the Secure banked instances of the [CNTP_CTL](#), [CNTP_CVAL](#), and [CNTP_TVAL](#) registers, and the Non-secure EL1 physical timer uses the Non-secure instances of the same registers.

[The AArch32 view of the Generic Timer on page G5-4222](#) describes these components.

The system level memory-mapped implementation of the Generic Timer

The memory-mapped registers that control the components of the system level implementation of the Generic Timer are grouped into *frames*. The Generic Timer architecture defines the offset of each register within its frame, but the base address of each frame is IMPLEMENTATION DEFINED, and defined by the system.

Each system level component has one or two register frames. The possible system level components are:

The memory-mapped counter module, required

This module controls the system counter. It has two frames:

- A control frame, CNTControlBase.
- A status frame, CNTReadBase.

The memory-mapped timer control module, required

The system level implementation of the Generic Timer can provide up to eight timers, and the memory-mapped timer control module identifies:

- Which timers are implemented.
- The features of each implemented timer.

This module has a single frame, CNTCTLBase.

Memory-mapped timers, optional

An implemented memory-mapped timer:

- Must provide a privileged view of the timer, in the CNTBaseN frame.

- Optionally, provides an unprivileged view of the timer in the CNTEL0BaseN frame.

N is the timer number, and the corresponding frame number, in the range 0-7.

[Chapter II System Level Implementation of the Generic Timer](#) describes these components.

G5.1.2 The system counter

The Generic Timer provides a system counter with the following specification:

| | |
|------------------|--|
| Width | At least 56 bits wide. The value returned by any 64-bit read of the counter is zero-extended to 64 bits. |
| Frequency | Increments at a fixed frequency, typically in the range 1-50MHz. Can support one or more alternative operating modes in which it increments by larger amounts at a lower frequency, typically for power-saving. |
| Roll-over | Roll-over time of not less than 40 years. |
| Accuracy | ARM does not specify a required accuracy, but recommends that the counter does not gain or lose more than ten seconds in a 24-hour period. Use of lower-frequency modes must not affect the implemented accuracy. |
| Start-up | Starts operating from zero. |

The system counter, once configured and running, must provide a uniform view of system time. More precisely, it must be impossible for the following sequence of events to show system time going backwards:

1. Device A reads the time from the system counter.
2. Device A communicates with another agent in the system, Device B.
3. After recognizing the communication from Device A, Device B reads the time from the system counter.

The system counter must be implemented in an always-on power domain.

To support lower-power operating modes, the counter can increment by larger amounts at a lower frequency. For example, a 10MHz system counter might either increment:

- By 1 at 10MHz.
- By 500 at 20kHz, when the system lowers the clock frequency, to reduce power consumption.

In this case, the counter must support transitions between high-frequency, high-precision operation, and lower-frequency, lower-precision operation, without any impact on the required accuracy of the counter.

The **CNTFRQ** register is intended to hold a copy of the current clock frequency to allow fast reference to this frequency by software running on the PE. For more information see [Initializing and reading the system counter frequency](#).

The mechanism by which the count from the system counter is distributed to system components is IMPLEMENTATION DEFINED, but each PE with a System register interface to the system counter must have a counter input that can capture each increment of the counter.

———— Note —————

So that the system counter can be clocked independently from the PE hardware, the count value might be distributed using a Gray code sequence. [Gray-count scheme for timer distribution scheme on page II-5134](#) gives more information about this possibility.

Initializing and reading the system counter frequency

The **CNTFRQ** register must be programmed to the clock frequency of the system counter. Typically, this is done only during the system boot process, by using the System register interface to write the system counter frequency to the **CNTFRQ** register. Only software executing at the highest implemented Exception level can write to **CNTFRQ**.

Note

The [CNTFRQ](#) register is UNKNOWN at reset, and therefore the counter frequency must be set as part of the system boot process.

Software can read the [CNTFRQ](#) register, to determine the current system counter frequency, in the following states and modes:

- Hyp mode.
- Secure PL1 modes and Non-secure EL1 modes.
- When [CNTKCTL.PL0PCTEN](#) is set to 1, Secure and Non-secure EL0 modes.

Memory-mapped controls of the system counter

Some system counter controls are accessible only through the memory-mapped interface to the system counter. These controls are:

- Enabling and disabling the counter.
- Setting the counter value.
- Changing the operating mode, to change the update frequency and increment value.
- Enabling Halt-on-debug, that a debugger can then use to suspend counting.

For descriptions of these controls, see [Chapter 11 System Level Implementation of the Generic Timer](#).

G5.2 The AArch32 view of the Generic Timer

The following sections describe the components and features of a PE implementation of the Generic Timer, as seen from AArch32 state:

- [The physical counter.](#)
- [The virtual counter.](#)
- [Event streams on page G5-4223.](#)
- [Timers on page G5-4224.](#)

G5.2.1 The physical counter

The PE includes a physical counter that contains the count value of the system counter. The `CNTPCT` register holds the current physical counter value.

Accessing the physical counter

Software with sufficient privilege can read `CNTPCT` using a 64-bit System register read.

`CNTPCT`:

- Is always accessible from Secure PL1 modes and from Non-secure Hyp mode.
- Is accessible from Non-secure EL1 modes when the value of `CNTHCTL.PL1PCTEN` is 1. When the value of `CNTHCTL.PL1PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure EL1 modes is trapped to Hyp mode.
- Is accessible from Secure User mode when the value of `CNTKCTL.PL0PCTEN` is 1. When the value of `CNTKCTL.PL0PCTEN` is 0, any attempt to access `CNTPCT` generates an UNDEFINED exception.
- Is accessible from Non-secure User mode when the value of `CNTHCTL.PL1PCTEN` is 1 and the value of `CNTKCTL.PL0PCTEN` is 1. Otherwise:
 - When the value of `CNTKCTL.PL0PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure User mode generates an UNDEFINED exception.
 - When the value of `CNTKCTL.PL0PCTEN` is 1 and the value of `CNTHCTL.PL1PCTEN` is 0, any attempt to access `CNTPCT` from Non-secure User mode is trapped to Hyp mode.

Reads of `CNTPCT` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTPCT` must be read, an ISB is used to ensure that the read of `CNTPCT` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop                ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB                ; without this, the CNTPCT could be read before the memory location in [R2]
                    ; has had the value 1 written to it
  MRS R1, CNTPCT
```

G5.2.2 The virtual counter

An implementation of the Generic Timer always includes a virtual counter, that indicates virtual time.

The virtual counter contains the value of the physical counter minus a 64-bit virtual offset. When executing in a Non-secure EL1 or EL0 mode, the virtual offset value relates to the current virtual machine.

The `CNTVOFF` register contains the virtual offset. `CNTVOFF` is only accessible:

- From Hyp mode.
- From Monitor mode only when `SCR.NS` is set to 1.

For more information see [Status of the CNTVOFF register on page G5-4223](#).

The `CNTVCT` register holds the current virtual counter value.

Accessing the virtual counter

Software with sufficient privilege can read `CNTVCT` using a 64-bit System register read.

`CNTVCT` is always accessible from Secure PL1 modes and from Non-secure EL1 and EL2 modes.

In addition, when `CNTKCTL.PLOVCTEN` is set to 1, `CNTVCT` is accessible from EL0.

When `CNTKCTL.PLOVCTEN` is set to 0, any attempt to access `CNTVCT` from EL0 is UNDEFINED.

Reads of `CNTVCT` can occur speculatively and out of order relative to other instructions executed on the same PE.

For example, if a read from memory is used to obtain a signal from another agent that indicates that `CNTVCT` must be read, an ISB is used to ensure that the read of `CNTVCT` occurs after the signal has been read from memory, as shown in the following code sequence:

```
loop           ; polling for some communication to indicate a requirement to read the timer
  LDR R1, [R2]
  CMP R1, #1
  BNE loop
  ISB          ; without this, the CNTVCT could be read before the memory location in [R2]
              ; has had the value 1 written to it
  MRS R1, CNTVCT
```

Status of the CNTVOFF register

All implementations of the Generic Timer include the virtual counter. Therefore, conceptually, all implementations include the `CNTVOFF` register that defines the *virtual offset* between the physical count and the virtual count. `CNTVOFF` is only accessible at EL2 or above. If EL2 is not implemented, the virtual counter uses a fixed virtual offset of zero.

G5.2.3 Event streams

Any implementation of the Generic Timer can use the system counter to generate one or more *event streams*, to generate periodic wake-up events as part of the mechanism described in [Wait for Event mechanism and Send event on page D1-1599](#).

————— Note —————

An event stream might be used:

- To impose a time-out on a Wait For Event polling loop.
- To safeguard against any programming error that means an expected event is not generated.

An event stream is configured by:

- Selecting which bit, from the bottom 16 bits of a counter, triggers the event. This determines the frequency of the events in the stream.
- Selecting whether the event is generated on each 0 to 1 transition, or each 1 to 0 transition, of the selected counter bit.

The `CNTKCTL`.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the virtual counter.

In all implementations the `CNTHCTL`.{EVNTEN, EVNTDIR, EVNTI} fields define an event stream that is generated from the physical counter.

The operation of an event stream is as follows:

- The pseudocode variables PreviousCNTVCT and PreviousCNTPCT are initialized as:
// Variables used for generation of the timer event stream.

```
bits(64) PreviousCNTVCT = bits(64) UNKNOWN;
bits(64) PreviousCNTPCT = bits(64) UNKNOWN;
```

- The pseudocode functions TestEventCNTV() and TestEventCNTP() are called on each cycle of the PE clock.
- The TestEventCNTx() pseudocode template defines the functions TestEventCNTV() and TestEventCNTP():

```
// TestEventCNTx()
// =====

// Template for the TestEventCNTV() and TestEventCNTP() functions
// Describes operation when all Exception Levels are using AArch32:
// CNTxCT      is CNTVCT      or CNTPCT      64-bit count value
// CNTx_CTL    is CNTV_CTL    or CNTP_CTL    Control register
// PreviousCNTxCT is PreviousCNTVCT or PreviousCNTPCT

TestEventCNTx()
  if CNTx_CTL.EVNTEN == '1' then
    n = UInt(CNTx_CTL.EVNTI);
    SampleBit = CNTxCT<n>;
    PreviousBit = PreviousCNTxCT<n>;

    if CNTx_CTL.EVNTDIR == '0' then
      if PreviousBit == '0' && SampleBit == '1' then EventRegisterSet();
    else
      if PreviousBit == '1' && SampleBit == '0' then EventRegisterSet();

  PreviousCNTxCT = CNTxCT;

  return;
```

G5.2.4 Timers

In an implementation that includes EL3, in any implementation of the Generic Timer, the following timers are accessible from AArch32 state, provided the appropriate Exception level can use AArch32:

- A Non-secure EL1 physical timer. A Non-secure EL1 control determines whether this register is accessible from Non-secure EL0.
- A Secure PL1 physical timer. This timer:
 - Is accessible from Secure EL1 using AArch32 when EL3 is using AArch64.
 - Is accessible from Secure EL3 when EL3 is using AArch32.
 A Secure PL1 control determines whether this register is accessible from Secure EL0.

- A Non-secure EL2 physical timer.
- A virtual timer.

The output of each implemented timer:

- Provides an output signal to the system.
- If the PE interfaces to a *Generic Interrupt Controller* (GIC), signals a *Private Peripheral Interrupt* (PPI) to that GIC. In a multiprocessor implementation, each PE must use the same interrupt number for each timer.

Each timer is implemented as three registers:

- A 64-bit CompareValue register, that provides a 64-bit unsigned upcounter.
- A 32-bit TimerValue register, that provides a 32-bit signed downcounter.
- A 32-bit Control register.

In all implementations, the AArch32 System registers for the EL1 (or PL1) physical timer are Banked, to provide the Secure and Non-secure implementations of the timer. [Table G5-1](#) shows the Timer registers.

Table G5-1 Timer registers summary for the Generic Timer

| Timer register | Secure PL1/Non-secure EL1 physical timer | EL2 physical timer | Virtual timer |
|-----------------------|--|----------------------------|---------------------------|
| CompareValue register | CNTP_CVAL ^a | CNTHP_CVAL | CNTV_CVAL |
| TimerValue register | CNTP_TVAL ^a | CNTHP_TVAL | CNTV_TVAL |
| Control register | CNTP_CTL ^a | CNTHP_CTL | CNTV_CTL |

a. In AArch32 state, these registers are Banked to provide the Non-secure EL1 physical timer and the Secure PL1 physical timer.

The following sections describe:

- [Accessing the timer registers](#)
- [Operation of the CompareValue views of the timers on page G5-4226](#)
- [Operation of the TimerValue views of the timers on page G5-4226.](#)

Accessing the timer registers

For each timer, all timer registers have the same access permissions, as follows:

Secure PL1 and Non-secure EL1 physical timer

The Secure PL1 physical timer is accessible from Secure PL1 modes.

Non-secure software executing at EL2 controls access to the Non-secure EL1 physical timer from Non-secure EL1 modes. The Non-secure EL1 physical timer is accessible from Monitor mode when the value of [SCR.NS](#) is 1.

When access from PL1 or EL1 modes is permitted, [CNTKCTL.PLOPTEN](#) determines whether the registers are accessible from EL0. If an access is not permitted because [CNTKCTL.PLOPTEN](#) is set to 0, an attempted access from EL0 is UNDEFINED.

In all implementations:

- Except for accesses from Monitor mode, accesses are to the registers for the current Security state.
- For accesses from Monitor mode, the value of [SCR.NS](#) determines whether accesses are to the Secure or the Non-secure registers.

———— **Note** ————

Monitor mode is present only when EL3 is using AArch32.

- The Non-secure registers are accessible from Hyp mode.
- [CNTHCTL.PL1PCEN](#) determines whether the Non-secure registers are accessible from Non-secure EL1 modes. If this bit is set to 1, to enable access from Non-secure EL1 modes, [CNTKCTL.PLOPTEN](#) determines whether the registers are accessible from Non-secure EL0.

If an access is not permitted because [CNTHCTL.PL1PCEN](#) is set to 0, an attempted access from a Non-secure EL1 or EL0 mode generates a Hyp Trap exception.

However, if [CNTKCTL.PLOPTEN](#) is set to 0, this control takes priority, and an attempted access from EL0 is UNDEFINED.

EL2 physical timer Accessible from Hyp mode, and from Secure Monitor mode when [SCR_EL3.NS](#) is set to 1.

Virtual timer Accessible from Secure PL1 modes and Non-secure EL1 modes, and from Hyp mode.
CNTKCTL.PLOVTEN determines whether the registers are accessible from EL0 modes. If an access is not permitted because **CNTKCTL.PLOVTEN** is set to 0, an attempted access from EL0 is UNDEFINED.

Operation of the CompareValue views of the timers

The CompareValue view of a timer operates as a 64-bit upcounter. The timer condition is met when the appropriate counter reaches the value programmed into its CompareValue register. When the timer condition is met an interrupt is generated if the interrupt is not masked in the corresponding timer control register, **CNTP_CTL**, **CNTHP_CTL**, or **CNTV_CTL**. For **CNTP_CTL**, the interrupt is the same as the interrupt asserted by the Non-secure instance of the AArch64 register **CNTP_CTL_ELO**.

The operation of this view of a timer is:

$$\text{TimerConditionMet} = (((\text{Counter}[63:0] - \text{Offset}[63:0])[63:0] - \text{CompareValue}[63:0]) \geq 0)$$

Where:

TimerConditionMet Is TRUE if the timer condition for this counter is met, and FALSE otherwise.

Counter The physical counter value, that can be read from the **CNTPCT** register.

———— **Note** —————

The virtual counter value, that can be read from the **CNTVCT** register, is the value:

$$\frac{(\text{Counter} - \text{Offset})}{}$$

Offset For a physical timer it is zero, and for the virtual timer it is the virtual offset, held in the **CNTVOFF** register.

CompareValue The value of the appropriate CompareValue register, **CNTP_CVAL**, **CNTHP_CVAL**, or **CNTV_CVAL**.

In this view of a timer, Counter, Offset, and CompareValue are all 64-bit unsigned values.

———— **Note** —————

This means that a timer with a CompareValue of, or close to, 0xFFFF_FFFF_FFFF_FFFF might never meet its timer condition. However, there is no practical requirement to use values close to the counter wrap value.

Operation of the TimerValue views of the timers

The TimerValue view of a timer operates as a signed 32-bit downcounter. A TimerValue register is programmed with a count value. This value decrements on each increment of the appropriate counter, and the timer condition is met when the value reaches zero. When the timer condition is met, an interrupt is generated if the interrupt is not masked in the corresponding timer control register, **CNTP_CTL**, **CNTHP_CTL**, or **CNTV_CTL**.

This view of a timer depends on the following behavior of accesses to TimerValue registers:

Reads $\text{TimerValue} = (\text{CompareValue} - (\text{Counter} - \text{Offset}))[31:0]$

Writes $\text{CompareValue} = ((\text{Counter} - \text{Offset})[63:0] + \text{SignExtend}(\text{TimerValue}))[63:0]$

Where the arguments have the definitions used in *Operation of the CompareValue views of the timers*, and in addition:

TimerValue The value of a TimerValue register, **CNTP_TVAL**, **CNTHP_TVAL**, or **CNTV_TVAL**.

In this view of a timer, all values are signed, in standard two's complement form.

A read of a TimerValue register after the timer condition has been met indicates the time since the timer condition was met.

Note

- *Operation of the CompareValue views of the timers on page G5-4226* gives a strict definition of TimerConditionMet. However, provided that the TimerValue is not expected to wrap as a 32-bit signed value when decremented from 0x80000000, the TimerValue view can be used as giving an effect equivalent to:
TimerConditionMet = (TimerValue ≤ 0)
 - Programming TimerValue to a negative number with magnitude greater than (Counter–Offset) can lead to an arithmetic overflow that causes the CompareValue to be an extremely large positive value. This potentially delays meeting the timer condition for an extremely long period of time.
-

Chapter G6

AArch32 System Register Descriptions

This chapter describes each of the AArch32 System registers.

It contains the following sections:

- *About the AArch32 System registers* on page G6-4230.
- *General system control registers* on page G6-4231.
- *Debug registers* on page G6-4668.
- *Performance Monitors registers* on page G6-4758.

G6.1 About the AArch32 System registers

For general information about the AArch32 System registers, see:

- [About the System registers for VMSAv8-32 on page G4-4148.](#)
- [VMSAv8-32 organization of registers in the \(coproc == 0b1110\) encoding space on page G4-4172.](#)
- [VMSAv8-32 organization of registers in the \(coproc == 0b1111\) encoding space on page G4-4175.](#)
- [Functional grouping of VMSAv8-32 System registers on page G4-4193.](#)

The remainder of this chapter describes the AArch32 System registers, in the following sections:

- [General system control registers on page G6-4231.](#)
- [Debug registers on page G6-4668.](#)
- [Performance Monitors registers on page G6-4758.](#)
- [Generic Timer registers on page G6-4803.](#)

G6.2 General system control registers

This section lists the System registers in AArch32 state that are not part of one of the other listed groups.

G6.2.1 ACTLR, Auxiliary Control Register

The ACTLR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

ACTLR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

ACTLR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

ACTLR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TAC==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TACR==1`, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register ACTLR is architecturally mapped to AArch64 System register [ACTLR_EL1](#)[31:0].

Some bits might define global configuration settings, and be common to the Secure and Non-secure instances of the register.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR is a 32-bit register.

Field descriptions

The ACTLR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR:

To access the ACTLR:

MRC p15,0,<Rt>,c1,c0,1 ; Read ACTLR into Rt
MCR p15,0,<Rt>,c1,c0,1 ; Write Rt to ACTLR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0001 | 0000 | 001 |

G6.2.2 ACTLR2, Auxiliary Control Register 2

The ACTLR2 characteristics are:

Purpose

Provides additional space to the ACTLR register to hold IMPLEMENTATION DEFINED trap functionality for execution at EL1 and EL0.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

ACTLR2(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

ACTLR2(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

ACTLR2 is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TAC==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TACR==1`, Non-secure accesses to this register from EL1 are trapped to EL2 using AArch64.
- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register ACTLR2 is architecturally mapped to AArch64 System register [ACTLR_EL1](#)[63:32].

It is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed.

The implementation of this register can be detected by examining bits [7:4] of the [ID_MMFR4/ID_MMFR4_EL1](#) register.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ACTLR2 is a 32-bit register.

Field descriptions

The ACTLR2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ACTLR2:

To access the ACTLR2:

MRC p15,0,<Rt>,c1,c0,3 ; Read ACTLR2 into Rt
MCR p15,0,<Rt>,c1,c0,3 ; Write Rt to ACTLR2

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0001 | 0000 | 011 |

G6.2.3 ADFSR, Auxiliary Data Fault Status Register

The ADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Data Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

ADFSR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

ADFSR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

ADFSR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register ADFSR is architecturally mapped to AArch64 System register [AFSR0_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

ADFSR is a 32-bit register.

Field descriptions

The ADFSr bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the ADFSr:

To access the ADFSr:

MRC p15,0,<Rt>,c5,c1,0 ; Read ADFSr into Rt
 MCR p15,0,<Rt>,c5,c1,0 ; Write Rt to ADFSr

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0101 | 0001 | 000 |

G6.2.4 AIDR, Auxiliary ID Register

The AIDR characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED identification information.

The value of this register must be used in conjunction with the value of [MIDR](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [HCR.TID1](#)==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HCR_EL2.TID1](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HSTR.T0](#)==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HSTR_EL2.T0](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register AIDR is architecturally mapped to AArch64 System register [AIDR_EL1](#).

Attributes

AIDR is a 32-bit register.

Field descriptions

The AIDR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AIDR:

To access the AIDR:

MRC p15,1,<Rt>,c0,c0,7 ; Read AIDR into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 001 | 0000 | 0000 | 111 |

G6.2.5 AIFSR, Auxiliary Instruction Fault Status Register

The AIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for Prefetch Abort exceptions taken to EL1 modes, and EL3 modes when EL3 is implemented and is using AArch32.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

AIFSR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

AIFSR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

AIFSR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register AIFSR is architecturally mapped to AArch64 System register [AFSR1_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AIFSR is a 32-bit register.

Field descriptions

The AIFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AIFSR:

To access the AIFSR:

MRC p15,0,<Rt>,c5,c1,1 ; Read AIFSR into Rt
 MCR p15,0,<Rt>,c5,c1,1 ; Write Rt to AIFSR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0101 | 0001 | 001 |

G6.2.6 AMAIR0, Auxiliary Memory Attribute Indirection Register 0

The AMAIR0 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIRO.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

AMAIRO(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

AMAIRO(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

AMAIRO is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIRO(S) gives the value for memory accesses from Secure state.
- AMAIRO(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIRO and MAIR1.

In a typical implementation, AMAIRO and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3816 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register AMAIR0 is architecturally mapped to AArch64 System register `AMAIR_EL1[31:0]`.

When EL3 is using AArch32, write access to AMAIR0(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR0 is a 32-bit register.

Field descriptions

The AMAIR0 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR0:

To access the AMAIR0:

MRC p15,0,<Rt>,c10,c3,0 ; Read AMAIR0 into Rt
MCR p15,0,<Rt>,c10,c3,0 ; Write Rt to AMAIR0

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1010 | 0011 | 000 |

G6.2.7 AMAIR1, Auxiliary Memory Attribute Indirection Register 1

The AMAIR1 characteristics are:

Purpose

When using the Long-descriptor format translation tables for stage 1 translations, provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR1.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

AMAIR1(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

AMAIR1(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

AMAIR1 is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

This register is RES0 in the following cases:

- When an implementation does not provide any IMPLEMENTATION DEFINED memory attributes.
- When the Long-descriptor translation table format is not used.

If EL3 is implemented and is using AArch32:

- AMAIR1(S) gives the value for memory accesses from Secure state.
- AMAIR1(NS) gives the value for memory accesses from Non-secure states other than Hyp mode.

Any IMPLEMENTATION DEFINED memory attributes are additional qualifiers for the memory locations and must not change the architected behavior specified by MAIRO and MAIR1.

In a typical implementation, AMAIRO and AMAIR1 split into eight one-byte fields, corresponding to the MAIRn.Attr<n> fields, but the architecture does not require them to do so.

Traps and Enables

For a description of the prioritization of any generated exceptions, see *Synchronous exception prioritization for exceptions taken to AArch32 state* on page G1-3816 for exceptions taken to AArch32 state, and *Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548* for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If HCR.TVM==1, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.

- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register AMAIR1 is architecturally mapped to AArch64 System register `AMAIR_EL1`[63:32].

When EL3 is using AArch32, write access to AMAIR1(S) is disabled when the CP15SSDISABLE signal is asserted HIGH.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

AMAIR1 is a 32-bit register.

Field descriptions

The AMAIR1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the AMAIR1:

To access the AMAIR1:

MRC p15,0,<Rt>,c10,c3,1 ; Read AMAIR1 into Rt
MCR p15,0,<Rt>,c10,c3,1 ; Write Rt to AMAIR1

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1010 | 0011 | 001 |

G6.2.8 APSR, Application Program Status Register

The APSR characteristics are:

Purpose

Hold program status and control information.

Usage constraints

The APSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see *PSTATE and banked register access instructions* on page F1-2380.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

APSR is a 32-bit register.

Field descriptions

The APSR bit assignments are:

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

Bits [26:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

Bits [15:5]

Reserved, RES0.

Bit [4]

Reserved, RES1.

Bits [3:0]

Reserved, RES0.

G6.2.9 ATS12NSOPR, Address Translate Stages 1 and 2 Non-secure Only PL1 Read

The ATS12NSOPR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if reading from the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If EL3 is implemented and is using AArch64, execution of ATS12NSOPR in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS12NSOPR is a 32-bit System instruction.

Field descriptions

The ATS12NSOPR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOPR instruction:

The ATS12NSOPR instruction is executed as:

MCR p15,0,<Rt>,c7,c8,4 ; ATS12NSOPR operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 100 |

G6.2.10 ATS12NSOPW, Address Translate Stages 1 and 2 Non-secure Only PL1 Write

The ATS12NSOPW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL1 and the Non-secure state, with permissions as if writing to the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If EL3 is implemented and is using AArch64, execution of ATS12NSOPW in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS12NSOPW is a 32-bit System instruction.

Field descriptions

The ATS12NSOPW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOPW instruction:

The ATS12NSOPW instruction is executed as:

MCR p15,0,<Rt>,c7,c8,5 ; ATS12NSOPW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 101 |

G6.2.11 ATS12NSOUR, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Read

The ATS12NSOUR characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if reading from the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If EL3 is implemented and is using AArch64, execution of ATS12NSOUR in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS12NSOUR is a 32-bit System instruction.

Field descriptions

The ATS12NSOUR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOUR instruction:

The ATS12NSOUR instruction is executed as:

MCR p15,0,<Rt>,c7,c8,6 ; ATS12NSOUR operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 110 |

G6.2.12 ATS12NSOUW, Address Translate Stages 1 and 2 Non-secure Only Unprivileged Write

The ATS12NSOUW characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for PL0 and the Non-secure state, with permissions as if writing to the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If EL3 is implemented and is using AArch64, execution of ATS12NSOUW in Secure EL1 using AArch32 is trapped as an exception to EL3.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS12NSOUW is a 32-bit System instruction.

Field descriptions

The ATS12NSOUW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the stage 2 translation.

Executing the ATS12NSOUW instruction:

The ATS12NSOUW instruction is executed as:

MCR p15,0,<Rt>,c7,c8,7 ; ATS12NSOUW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 111 |

G6.2.13 ATS1CPR, Address Translate Stage 1 Current state PL1 Read

The ATS1CPR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if reading from the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1CPR is a 32-bit System instruction.

Field descriptions

The ATS1CPR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPR instruction:

The ATS1CPR instruction is executed as:

MCR p15,0,<Rt>,c7,c8,0 ; ATS1CPR operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 1000 | 000 |

G6.2.14 ATS1CPW, Address Translate Stage 1 Current state PL1 Write

The ATS1CPW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL1 and the current Security state, with permissions as if writing to the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1CPW is a 32-bit System instruction.

Field descriptions

The ATS1CPW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CPW instruction:

The ATS1CPW instruction is executed as:

MCR p15,0,<Rt>,c7,c8,1 ; ATS1CPW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 001 |

G6.2.15 ATS1CUR, Address Translate Stage 1 Current state Unprivileged Read

The ATS1CUR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if reading from the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1CUR is a 32-bit System instruction.

Field descriptions

The ATS1CUR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CUR instruction:

The ATS1CUR instruction is executed as:

MCR p15,0,<Rt>,c7,c8,2 ; ATS1CUR operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1000 | 010 |

G6.2.16 ATS1CUW, Address Translate Stage 1 Current state Unprivileged Write

The ATS1CUW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL0 and the current Security state, with permissions as if writing to the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1CUW is a 32-bit System instruction.

Field descriptions

The ATS1CUW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. In an implementation that includes EL2, when executed in Non-secure state, the resulting address is the IPA that is the output address of the stage 1 translation. Otherwise, the resulting address is a PA.

Executing the ATS1CUW instruction:

The ATS1CUW instruction is executed as:

MCR p15,0,<Rt>,c7,c8,3 ; ATS1CUW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 1000 | 011 |

G6.2.17 ATS1HR, Address Translate Stage 1 Hyp mode Read

The ATS1HR characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if reading from the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0, Mon) | EL3 (SCR.NS=0, !Mon) |
|----------|---------|----------|----------|----------------|---------------------|----------------------|
| - | - | - | WO | WO | WO | WO-UNPREDICTABLE |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see [Hyp mode VA to PA address translation instructions on page K1-5476](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1HR is a 32-bit System instruction.

Field descriptions

The ATS1HR input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Executing the ATS1HR instruction:

The ATS1HR instruction is executed as:

MCR p15,4,<Rt>,c7,c8,0 ; ATS1HR operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0111 | 1000 | 000 |

G6.2.18 ATS1HW, Address Translate Stage 1 Hyp mode Write

The ATS1HW characteristics are:

Purpose

Performs stage 1 address translation as defined for PL2 and the Non-secure state, with permissions as if writing to the given virtual address.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0, Mon) | EL3 (SCR.NS=0, !Mon) |
|----------|---------|----------|----------|----------------|---------------------|----------------------|
| - | - | - | WO | WO | WO | WO-UNPREDICTABLE |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | WO |

If this operation is executed in a Secure privileged mode other than Monitor mode, then the behavior is CONSTRAINED UNPREDICTABLE. For more information see [Hyp mode VA to PA address translation instructions on page K1-5476](#).

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

ATS1HW is a 32-bit System instruction.

Field descriptions

The ATS1HW input value bit assignments are:

Bits [31:0]

Input address for translation. The resulting address can be read from the [PAR](#).

This instruction takes a VA as input. The resulting address is the PA that is the output address of the translation.

Executing the ATS1HW instruction:

The ATS1HW instruction is executed as:

MCR p15,4,<Rt>,c7,c8,1 ; ATS1HW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0111 | 1000 | 001 |

G6.2.19 BPIALL, Branch Predictor Invalidate All

The BPIALL characteristics are:

Purpose

Invalidate all entries from branch predictors.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIALL is a 32-bit System instruction.

Field descriptions

BPIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the BPIALL instruction:

The BPIALL instruction is executed as:

MCR p15,0,<Rt>,c7,c5,6 ; BPIALL operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 0101 | 110 |

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

G6.2.20 BPIALLIS, Branch Predictor Invalidate All, Inner Shareable

The BPIALLIS characteristics are:

Purpose

Invalidate all entries from branch predictors Inner Shareable.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIALLIS is a 32-bit System instruction.

Field descriptions

BPIALLIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the BPIALLIS instruction:

The BPIALLIS instruction is executed as:

`MCR p15,0,<Rt>,c7,c1,6 ; BPIALLIS operation, ignoring the value in Rt`

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 0001 | 110 |

The PE ignores the value of `<Rt>`. Software does not have to write a value to this register before issuing this instruction.

G6.2.21 BPIMVA, Branch Predictor Invalidate by VA

The BPIMVA characteristics are:

Purpose

Invalidate virtual address from branch predictors.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

In an implementation where the branch predictors are architecturally invisible, this instruction can execute as a NOP.

Attributes

BPIMVA is a 32-bit System instruction.

Field descriptions

The BPIMVA input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the BPIMVA instruction:

The BPIMVA instruction is executed as:

MCR p15,0,<Rt>,c7,c5,7 ; BPIMVA operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 0101 | 111 |

G6.2.22 CCSIDR, Current Cache Size ID Register

The CCSIDR characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

If [CSSELR.Level](#) indicates a cache that is not implemented, then on a read of the CCSIDR the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR read is treated as NOP.
- The CCSIDR read is UNDEFINED.
- The CCSIDR read returns an UNKNOWN value.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [HCR.TID2](#)==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HCR_EL2.TID2](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HSTR.T0](#)==1, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HSTR_EL2.T0](#)==1, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CCSIDR is architecturally mapped to AArch64 System register [CCSIDR_EL1](#).

The implementation includes one CCSIDR for each cache that it can access. [CSSELR](#) and the Security state select which Cache Size ID Register is accessible.

Attributes

CCSIDR is a 32-bit register.

Field descriptions

The CCSIDR bit assignments are:

UNKNOWN, bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

($\text{Log}_2(\text{Number of bytes in cache line})$) - 4. For example:

For a line length of 16 bytes: $\text{Log}_2(16) = 4$, LineSize entry = 0. This is the minimum line length.

For a line length of 32 bytes: $\text{Log}_2(32) = 5$, LineSize entry = 1.

———— **Note** ————

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Accessing the CCSIDR:

To access the CCSIDR:

MRC p15,1,<Rt>,c0,c0,0 ; Read CCSIDR into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 001 | 0000 | 0000 | 000 |

G6.2.23 CLIDR, Cache Level ID Register

The CLIDR characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TID2==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TID2==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T0==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states. AArch32 System register CLIDR is architecturally mapped to AArch64 System register [CLIDR_EL1](#).

Attributes

CLIDR is a 32-bit register.

Field descriptions

The CLIDR bit assignments are:

| 31 | 30 | 29 | 27 | 26 | 24 | 23 | 21 | 20 | 18 | 17 | 15 | 14 | 12 | 11 | 9 | 8 | 6 | 5 | 3 | 2 | 0 |
|-----|------|-----|-------|--------|--------|--------|--------|--------|--------|--------|----|----|----|----|---|---|---|---|---|---|---|
| ICB | LoUU | LoC | LoUIS | Ctype7 | Ctype6 | Ctype5 | Ctype4 | Ctype3 | Ctype2 | Ctype1 | | | | | | | | | | | |

ICB, bits [31:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The possible values are:

- 00 Not disclosed by this mechanism.
- 01 L1 cache is the highest Inner Cacheable level.
- 10 L2 cache is the highest Inner Cacheable level.
- 11 L3 cache is the highest Inner Cacheable level.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

Ctype<n>, bits [3(n-1)+2:3(n-1)], for n = 1 to 7

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

- 000 No cache.
- 001 Instruction cache only.
- 010 Data cache only.
- 011 Separate instruction and data caches.
- 100 Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 000, the values of Ctype4 to Ctype7 must be ignored.

Accessing the CLIDR:

To access the CLIDR:

MRC p15,1,<Rt>,c0,c0,1 ; Read CLIDR into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 001 | 0000 | 0000 | 001 |

G6.2.24 CONTEXTIDR, Context ID Register

The CONTEXTIDR characteristics are:

Purpose

Identifies the current Process Identifier and, when using the Short-descriptor translation table format, the Address Space Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

CONTEXTIDR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

CONTEXTIDR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

CONTEXTIDR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T13==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T13==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register CONTEXTIDR is architecturally mapped to AArch64 System register [CONTEXTIDR_ELI](#).

The register format depends on whether address translation is using the Long-descriptor or the Short-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CONTEXTIDR is a 32-bit register.

Field descriptions

The CONTEXTIDR bit assignments are:

When *TTBCR.EAE*==0:

PROCID, bits [31:8]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

ASID, bits [7:0]

Address Space Identifier. This field is programmed with the value of the current ASID.

When *TTBCR.EAE*==1:

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Accessing the CONTEXTIDR:

To access the CONTEXTIDR:

MRC p15,0,<Rt>,c13,c0,1 ; Read CONTEXTIDR into Rt
MCR p15,0,<Rt>,c13,c0,1 ; Write Rt to CONTEXTIDR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1101 | 0000 | 001 |

G6.2.25 CP15DMB, Data Memory Barrier System instruction

The CP15DMB characteristics are:

Purpose

Performs a Data Memory Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [DMB](#) instruction instead.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| WO | WO | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `SCTLR.CP15BEN==0`, execution of this instruction at PL0 and PL1 is UNDEFINED.
- If `SCTLR_EL1.CP15BEN==0`, execution of this instruction at PL0 is UNDEFINED.
- If `HSCTLR.CP15BEN==0`, execution of this instruction at PL2 is UNDEFINED.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

CP15DMB is a 32-bit System instruction.

Field descriptions

CP15DMB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15DMB instruction:

The CP15DMB instruction is executed as:

`MCR p15,0,<Rt>,c7,c10,5 ; CP15DMB operation, ignoring the value in Rt`

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1010 | 101 |

G6.2.26 CP15DSB, Data Synchronization Barrier System instruction

The CP15DSB characteristics are:

Purpose

Performs a Data Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [DSB](#) instruction instead.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| WO | WO | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `SCTLR.CP15BEN==0`, execution of this instruction at PL0 and PL1 is UNDEFINED.
- If `SCTLR_EL1.CP15BEN==0`, execution of this instruction at PL0 is UNDEFINED.
- If `HSCTLR.CP15BEN==0`, execution of this instruction at PL2 is UNDEFINED.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

CP15DSB is a 32-bit System instruction.

Field descriptions

CP15DSB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15DSB instruction:

The CP15DSB instruction is executed as:

MCR p15,0,<Rt>,c7,c10,4 ; CP15DSB operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1010 | 100 |

G6.2.27 CP15ISB, Instruction Synchronization Barrier System instruction

The CP15ISB characteristics are:

Purpose

Performs an Instruction Synchronization Barrier.

ARM deprecates any use of this operation, and strongly recommends that software use the [ISB](#) instruction instead.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| WO | WO | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| WO | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `SCTLR.CP15BEN==0`, execution of this instruction at PL0 and PL1 is UNDEFINED.
- If `SCTLR_EL1.CP15BEN==0`, execution of this instruction at PL0 is UNDEFINED.
- If `HSCTLR.CP15BEN==0`, execution of this instruction at PL2 is UNDEFINED.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL0 and EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

CP15ISB is a 32-bit System instruction.

Field descriptions

CP15ISB ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the CP15ISB instruction:

The CP15ISB instruction is executed as:

MCR p15,0,<Rt>,c7,c5,4 ; CP15ISB operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 0101 | 100 |

G6.2.28 CPACR, Architectural Feature Access Control Register

The CPACR characteristics are:

Purpose

Controls access to trace, and to Advanced SIMD and floating-point functionality from EL0, EL1, and EL3.

In an implementation that includes EL2, the CPACR has no effect on instructions executed at EL2.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCPTR.TCPAC==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `CPTR_EL2.TCPAC==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `CPTR_EL3.TCPAC==1`, accesses to this register from EL1 and EL2 are trapped to EL3.
- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CPACR is architecturally mapped to AArch64 System register [CPACR_EL1](#).

Bits in the `NSACR` control Non-secure access to the CPACR fields. See the field descriptions for more information.

Note

In the register field descriptions, controls are described as applying at specified Privilege levels. This is because, in Secure state, a PL1 control:

- Applies to execution in a Secure EL3 mode when EL3 is using AArch32.
- Applies to execution in a Secure EL1 mode when EL3 is using AArch64.

See [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#).

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CPACR is a 32-bit register.

Field descriptions

The CPACR bit assignments are:

ASEDIS, bit [31]

Disables PL0 and PL1 execution of Advanced SIMD instructions.

- 0 This control permits execution of Advanced SIMD instructions at PL0 and PL1.
- 1 All instruction encodings that are Advanced SIMD instruction encodings, but are not also floating-point instruction encodings, are UNDEFINED at PL0 and PL1.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of `NSACR.NSASEDIS` is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see [Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2306](#).

See the description of `CPACR.cp10` for a list of other controls that can disable or trap execution of Advanced SIMD instructions in AArch32 state.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [30:29]

Reserved, RES0.

TRCDIS, bit [28]

Traps PL0 and PL1 System register accesses to all implemented trace registers to Undefined mode.

- 0 This control has no effect on PL0 and PL1 System register accesses to trace registers.
- 1 PL0 and PL1 System register accesses to all implemented trace registers are trapped to Undefined mode.

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, this field is RES0. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of `NSACR.NSTRCDIS` is 1, this field behaves as RAO/WI in Non-secure state, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

Note

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED.
- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [27:24]

Reserved, RES0.

cp11, bits [23:22]

The value of this field is ignored. If this field is programmed with a different value to the cp10 field then this field is UNKNOWN on a direct read of the CPACR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of **NSACR**.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

cp10, bits [21:20]

Defines the access rights for the floating-point and Advanced SIMD functionality. Possible values of the field are:

- | | |
|----|--|
| 00 | PL0 and PL1 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED. |
| 01 | PL0 accesses to floating-point and Advanced SIMD registers or instructions are UNDEFINED. |
| 10 | Reserved. The effect of programming this field to this value is CONSTRAINED UNPREDICTABLE. See <i>Reserved values in System and memory-mapped registers and translation table entries</i> on page K1-5477. |
| 11 | This control permits full access to the floating-point and Advanced SIMD functionality from PL0 and PL1. |

The floating-point and Advanced SIMD features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the **FPSCR**, **FPSID**, **MVFR0**, **MVFR1**, **MVFR2**, or **FPEXC** System registers.

Note

The **CPACR** has no effect on floating-point and Advanced SIMD accesses from PL2. These can be disabled by the **HCPTR**.TCP10 field.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES0.

In Non-secure state, if EL3 is implemented and is using AArch32, when the value of **NSACR**.cp10 is 0, this field behaves as RAZ/WI, regardless of its actual value.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
 - HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
 - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
- For Advanced SIMD instructions only:
 - CPACR.ASEDIS.
 - If executing in Non-secure state, HCPTR.TASE and NSACR.NSTRCDIS.

See the descriptions of the controls for more information.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [19:0]

Reserved, RES0.

Accessing the CPACR:

To access the CPACR:

MRC p15,0,<Rt>,c1,c0,2 ; Read CPACR into Rt
MCR p15,0,<Rt>,c1,c0,2 ; Write Rt to CPACR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0001 | 0000 | 010 |

G6.2.29 CPSR, Current Program Status Register

The CPSR characteristics are:

Purpose

Holds PE status and control information.

Usage constraints

The CPSR can be read using the MRS instruction and written using the MSR (immediate) or MSR (register) instructions. For more details on the instruction syntax, see *PSTATE and banked register access instructions* on page F1-2380.

Traps and Enables

There are no traps or enables affecting this register.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

CPSR is a 32-bit register.

Field descriptions

The CPSR bit assignments are:

N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then N is set to 1 if the result was negative, and N is set to 0 if the result was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

IT block state bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:20]

Reserved, RES0.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

IT block state bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is 0b00000000 when no IT block is active.

E, bit [9]

Endianness state bit. Controls the load and store endianness for data accesses:

- 0 Little-endian operation
- 1 Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any Exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any Exception level other than EL0.

A, bit [8]

SError interrupt mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

- 0 Exception not masked.
- 1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Indicates the AArch32 instruction set state. Possible values of this bit are:

- 0 A32 state.
- 1 T32 state.

Bit [4]

Reserved, RES1.

M[3:0], bits [3:0]

Current PE mode. Possible values are:

| M[3:0] | Mode |
|---------------|-------------|
| 0b0000 | User |
| 0b0001 | FIQ |
| 0b0010 | IRQ |
| 0b0011 | Supervisor |
| 0b0110 | Monitor |
| 0b0111 | Abort |
| 0b1010 | Hyp |
| 0b1011 | Undefined |
| 0b1111 | System |

Other values are reserved.

G6.2.30 CSSELR, Cache Size Selection Register

The CSSELR characteristics are:

Purpose

Selects the current Cache Size ID Register, [CCSIDR](#), by specifying the required cache level and the cache type (either instruction or data cache).

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

CSSELR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

CSSELR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

CSSELR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

If CSSELR.Level is programmed to a cache level that is not implemented, then a read of CSSELR is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR.{Level, InD}.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [HCR.TID2](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If [HCR_EL2.TID2](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.
- If [HSTR.T0](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If [HSTR_EL2.T0](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register CSSELR is architecturally mapped to AArch64 System register [CSSELR_EL1](#).

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

CSSELR is a 32-bit register.

Field descriptions

The CSSELR bit assignments are:

Bits [31:4]

Reserved, RES0.

Level, bits [3:1]

Cache level of required cache. Permitted values are:

- 000 Level 1 cache
- 001 Level 2 cache
- 010 Level 3 cache
- 011 Level 4 cache
- 100 Level 5 cache
- 101 Level 6 cache
- 110 Level 7 cache

All other values are reserved.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

InD, bit [0]

Instruction not Data bit. Permitted values are:

- 0 Data or unified cache.
- 1 Instruction cache.

If CSSELR.Level is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR is UNKNOWN.

Accessing the CSSELR:

To access the CSSELR:

MRC p15,2,<Rt>,c0,c0,0 ; Read CSSELR into Rt
 MCR p15,2,<Rt>,c0,c0,0 ; Write Rt to CSSELR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 010 | 0000 | 0000 | 000 |

G6.2.31 CTR, Cache Type Register

The CTR characteristics are:

Purpose

Provides information about the architecture of the caches.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TID2==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TID2==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T0==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register CTR is architecturally mapped to AArch64 System register [CTR_EL0](#).

Attributes

CTR is a 32-bit register.

Field descriptions

The CTR bit assignments are:

Bit [31]

Reserved, RES1.

Bits [30:28]

Reserved, RES0.

CWG, bits [27:24]

Cache Writeback Granule. \log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of 0b0000 indicates that this register does not provide Cache Writeback Granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache Writeback Granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

ERG, bits [23:20]

Exclusives Reservation Granule. \log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

A value of 0b0000 indicates that this register does not provide Exclusives Reservation Granule information and the architectural maximum of 512 words (2KB) must be assumed.

Values greater than 0b1001 are reserved.

DminLine, bits [19:16]

\log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache. Possible values of this field are:

- | | |
|----|---|
| 01 | ASID-tagged Virtual Index, Virtual Tag (AIVIVT) |
| 10 | Virtual Index, Physical Tag (VIPT) |
| 11 | Physical Index, Physical Tag (PIPT) |

Other values are reserved.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

\log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

Accessing the CTR:

To access the CTR:

MRC p15,0,<Rt>,c0,c0,1 ; Read CTR into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0000 | 0000 | 001 |

G6.2.32 DACR, Domain Access Control Register

The DACR characteristics are:

Purpose

Defines the access permission for each of the sixteen memory domains.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

DACR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

DACR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

DACR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T3==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T3==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register DACR is architecturally mapped to AArch64 System register [DACR32_EL2](#).

When EL3 is using AArch32, write access to DACR(S) is disabled when the CP15SDISABLE signal is asserted HIGH.

This register has no function when `TTBCR.EAE` is set to 1, to select the Long-descriptor translation table format.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DACR is a 32-bit register.

Field descriptions

The DACR bit assignments are:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| D15 | D14 | D13 | D12 | D11 | D10 | D9 | D8 | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | | | | | | | | | | | | | | | | | |

D<n>, bits [2n+1:2n], for n = 0 to 15

Domain n access permission, where n = 0 to 15. Permitted values are:

- 00 No access. Any access to the domain generates a Domain fault.
- 01 Client. Accesses are checked against the permission bits in the translation tables.
- 11 Manager. Accesses are not checked against the permission bits in the translation tables.

The value 10 is reserved.

Accessing the DACR:

To access the DACR:

MRC p15,0,<Rt>,c3,c0,0 ; Read DACR into Rt
MCR p15,0,<Rt>,c3,c0,0 ; Write Rt to DACR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0011 | 0000 | 000 |

G6.2.33 DCCIMVAC, Data Cache line Clean and Invalidate by VA to PoC

The DCCIMVAC characteristics are:

Purpose

Clean and Invalidate data or unified cache line by virtual address to PoC.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPC==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPC==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCCIMVAC performs the same function as AArch64 System instruction [DC CIVAC](#).

Attributes

DCCIMVAC is a 32-bit System instruction.

Field descriptions

The DCCIMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCIMVAC instruction:

The DCCIMVAC instruction is executed as:

MCR p15,0,<Rt>,c7,c14,1 ; DCCIMVAC operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1110 | 001 |

G6.2.34 DCCISW, Data Cache line Clean and Invalidate by Set/Way

The DCCISW characteristics are:

Purpose

Clean and Invalidate data or unified cache line by set/way.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TSW==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TSW==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCCISW performs the same function as AArch64 System instruction [DC C1SW](#).

Attributes

DCCISW is a 32-bit System instruction.

Field descriptions

The DCCISW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCCISW instruction:

The DCCISW instruction is executed as:

MCR p15,0,<Rt>,c7,c14,2 ; DCCISW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 1110 | 010 |

G6.2.35 DCCMVAC, Data Cache line Clean by VA to PoC

The DCCMVAC characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoC.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPC==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPC==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCCMVAC performs the same function as AArch64 System instruction [DC CVAC](#).

Attributes

DCCMVAC is a 32-bit System instruction.

Field descriptions

The DCCMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCMVAC instruction:

The DCCMVAC instruction is executed as:

MCR p15,0,<Rt>,c7,c10,1 ; DCCMVAC operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1010 | 001 |

G6.2.36 DCCMVAU, Data Cache line Clean by VA to PoU

The DCCMVAU characteristics are:

Purpose

Clean data or unified cache line by virtual address to PoU.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCCMVAU performs the same function as AArch64 System instruction [DC CVAU](#).

Attributes

DCCMVAU is a 32-bit System instruction.

Field descriptions

The DCCMVAU input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCCMVAU instruction:

The DCCMVAU instruction is executed as:

MCR p15,0,<Rt>,c7,c11,1 ; DCCMAU operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 1011 | 001 |

G6.2.37 DCCSW, Data Cache line Clean by Set/Way

The DCCSW characteristics are:

Purpose

Clean data or unified cache line by set/way.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TSW==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TSW==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCCSW performs the same function as AArch64 System instruction [DC CSW](#).

Attributes

DCCSW is a 32-bit System instruction.

Field descriptions

The DCCSW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCCSW instruction:

The DCCSW instruction is executed as:

MCR p15,0,<Rt>,c7,c10,2 ; DCCSW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 1010 | 010 |

G6.2.38 DCIMVAC, Data Cache line Invalidate by VA to PoC

The DCIMVAC characteristics are:

Purpose

Invalidate data or unified cache line by virtual address to PoC.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

It is IMPLEMENTATION DEFINED whether, when this instruction is executed, it can generate a watchpoint. If this instruction can generate a watchpoint this is prioritized in the same way as other watchpoints.

At EL1, this instruction must be performed as **DCCIMVAC** if all of the following apply:

- EL2 is implemented and either:
 - EL2 is using AArch64 and the value of **HCR_EL2.VM** is 1.
 - EL2 is using AArch32 and the value of **HCR.VM** is 1.
- Execution is in Non-secure state, or EL3 is not implemented.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If **HCR.TPC**==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If **HCR_EL2.TPC**==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If **HSTR.T7**==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If **HSTR_EL2.T7**==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCIMVAC performs the same function as AArch64 System instruction **DC IVAC**.

Attributes

DCIMVAC is a 32-bit System instruction.

Field descriptions

The DCIMVAC input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the DCIMVAC instruction:

The DCIMVAC instruction is executed as:

MCR p15,0,<Rt>,c7,c6,1 ; DCIMVAC operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 0110 | 001 |

It is IMPLEMENTATION DEFINED whether, when this instruction is executed, it can generate a watchpoint. If this instruction can generate a watchpoint this is prioritized in the same way as other watchpoints.

G6.2.39 DCISW, Data Cache line Invalidate by Set/Way

The DCISW characteristics are:

Purpose

Invalidate data or unified cache line by set/way.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

At EL1, this operation must be performed as [DCCISW](#) if all of the following apply:

- EL2 is implemented and either:
 - EL2 is using AArch64 and the value of [HCR_EL2](#).{SWIO, VM} is not {0, 0}.
 - EL2 is using AArch32 and the value of [HCR](#).{SWIO, VM} is not {0, 0}.
- Execution is in Non-secure state, or EL3 is not implemented.

If this instruction is executed with a set, way or level argument that is larger than the value supported by the implementation then the behavior is CONstrained UNPREDICTABLE and one of the following occurs:

- The instruction is UNDEFINED
- The instruction performs cache maintenance on one of:
 - No cache lines.
 - A single arbitrary cache line.
 - Multiple arbitrary cache lines.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [HCR](#).TSW==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If [HCR_EL2](#).TSW==1, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If [HSTR](#).T7==1, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If [HSTR_EL2](#).T7==1, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction DCISW performs the same function as AArch64 System instruction [DC ISW](#).

Attributes

DCISW is a 32-bit System instruction.

Field descriptions

The DCISW input value bit assignments are:

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

$A = \text{Log}_2(\text{ASSOCIATIVITY})$, $L = \text{Log}_2(\text{LINELEN})$, $B = (L + S)$, $S = \text{Log}_2(\text{NSETS})$.

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Executing the DCISW instruction:

The DCISW instruction is executed as:

MCR p15,0,<Rt>,c7,c6,2 ; DCISW operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0111 | 0110 | 010 |

G6.2.40 DFAR, Data Fault Address Register

The DFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

DFAR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

DFAR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

DFAR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T6==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T6==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register DFAR(NS) is architecturally mapped to AArch64 System register [FAR_EL1](#)[31:0].

AArch32 System register DFAR(S) is architecturally mapped to AArch32 System register [HDFAR](#) when EL2 is implemented.

AArch32 System register DFAR(S) is architecturally mapped to AArch64 System register [FAR_EL2](#)[31:0] when EL2 is implemented.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

DFAR is a 32-bit register.

Field descriptions

The DFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Data Abort exception.

Accessing the DFAR:

To access the DFAR:

MRC p15,0,<Rt>,c6,c0,0 ; Read DFAR into Rt
MCR p15,0,<Rt>,c6,c0,0 ; Write Rt to DFAR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0110 | 0000 | 000 |

G6.2.41 DFSR, Data Fault Status Register

The DFSR characteristics are:

Purpose

Holds status information about the last data fault.

Usage constraints

If EL3 is implemented and is using AArch32, there are separate Secure and Non-secure instances of this register.

DFSR(S) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | - | - | RW |

DFSR(NS) is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | - |

If EL3 is not implemented, or is implemented and is using AArch64, there is a single instance of this register.

DFSR is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TVM==1`, Non-secure write accesses to this register from EL1 are trapped to EL2.
- If `HCR.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TRVM==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register DFSR is architecturally mapped to AArch64 System register [ESR_EL1](#).

The current translation table format determines which format of the register is used.

RW fields in this register reset to architecturally UNKNOWN values.

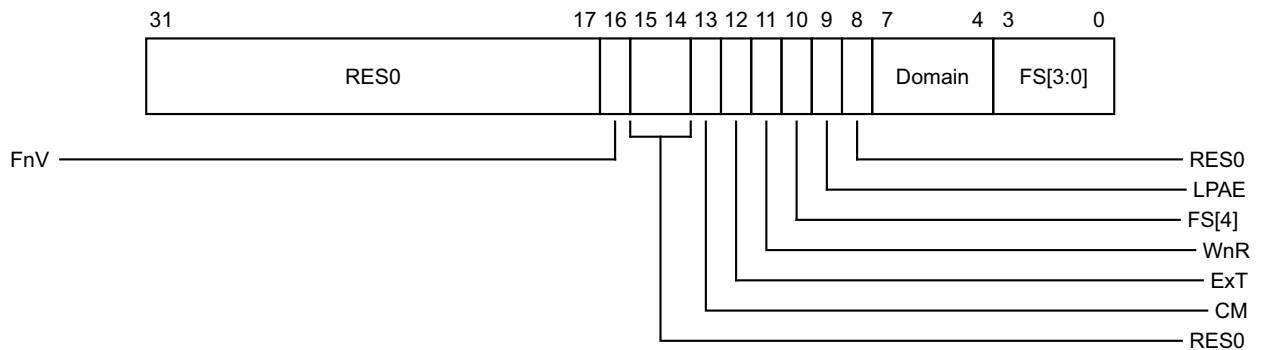

Attributes

DFSR is a 32-bit register.

Field descriptions

The DFSR bit assignments are:

When $TTBCR.EAE=0$:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

0 **DFAR** is valid.

1 **DFAR** is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

Bits [15:14]

Reserved, RES0.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

0 Abort not caused by execution of a cache maintenance instruction.

1 Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.

FS[4], bit [10]

See FS[3:0], bits [3:0] for description of the FS field.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bit [8]

Reserved, RES0.

Domain, bits [7:4]

The domain of the fault address.

ARM deprecates any use of this field, see [The Domain field in the DFSR on page G4-4129](#).

This field is UNKNOWN for certain faults where the DFSR is updated and reported using the Short-descriptor FSR encodings, see [Table G4-28 on page G4-4133](#).

FS[3:0], bits [3:0]

Fault status bits. Interpreted with bit [10]. Possible values of FS[4:0] are:

- 00001 Alignment fault
- 00010 Debug exception
- 00011 Access flag fault, level 1
- 00100 Fault on instruction cache maintenance
- 00101 Translation fault, level 1
- 00110 Access flag fault, level 2
- 00111 Translation fault, level 2
- 01000 Synchronous external abort, not on translation table walk
- 01001 Domain fault, level 1
- 01011 Domain fault, level 2
- 01100 Synchronous external abort, on translation table walk, level 1
- 01101 Permission fault, level 1
- 01110 Synchronous external abort, on translation table walk, level 2
- 01111 Permission fault, level 2
- 10000 TLB conflict abort
- 10100 IMPLEMENTATION DEFINED fault (Lockdown fault)
- 10101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
- 10110 SError interrupt
- 11000 SError interrupt, from a parity or ECC error on memory access

- 11001 Synchronous parity or ECC error on memory access, not on translation table walk
- 11100 Synchronous parity or ECC error on translation table walk, level 1
- 11110 Synchronous parity or ECC error on translation table walk, level 2

All other values are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Short-descriptor translation table lookup* on page G4-4129.

When TTBCR.EAE=1:

Bits [31:17]

Reserved, RES0.

FnV, bit [16]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 DFAR is valid.
- 1 DFAR is not valid, and holds an UNKNOWN value.

This field is only valid for a Synchronous external abort other than a Synchronous external abort on a translation table walk. It is RES0 for all other Data Abort exceptions.

Bits [15:14]

Reserved, RES0.

CM, bit [13]

Cache maintenance fault. For synchronous faults, this bit indicates whether a cache maintenance instruction generated the fault. The possible values of this bit are:

- 0 Abort not caused by execution of a cache maintenance instruction.
- 1 Abort caused by execution of a cache maintenance instruction.

On a synchronous Data Abort on a translation table walk, this bit is UNKNOWN.

On an asynchronous fault, this bit is UNKNOWN.

ExT, bit [12]

External abort type. This bit can be used to provide an IMPLEMENTATION DEFINED classification of external aborts.

In an implementation that does not provide any classification of external aborts, this bit is RES0.

For aborts other than external aborts this bit always returns 0.

WnR, bit [11]

Write not Read bit. Indicates whether the abort was caused by a write or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on the cache maintenance and address translation System instructions in the (coproc==1111) encoding space this bit always returns a value of 1.

Bit [10]

Reserved, RES0.

LPAE, bit [9]

On taking a Data Abort exception, this bit is set as follows:

- 0 Using the Short-descriptor translation table formats.
- 1 Using the Long-descriptor translation table formats.

Hardware does not interpret this bit to determine the behavior of the memory system, and therefore software can set this bit to 0 or 1 without affecting operation.

Bits [8:6]

Reserved, RES0.

STATUS, bits [5:0]

Fault status bits. Possible values of this field are:

- 000000 Address size fault in [TTBR0](#) or [TTBR1](#)
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3
- 000101 Translation fault, level 1
- 000110 Translation fault, level 2
- 000111 Translation fault, level 3
- 001001 Access flag fault, level 1
- 001010 Access flag fault, level 2
- 001011 Access flag fault, level 3
- 001101 Permission fault, level 1
- 001110 Permission fault, level 2
- 001111 Permission fault, level 3
- 010000 Synchronous external abort, not on translation table walk
- 010001 SError interrupt
- 010101 Synchronous external abort, on translation table walk, level 1
- 010110 Synchronous external abort, on translation table walk, level 2
- 010111 Synchronous external abort, on translation table walk, level 3
- 011000 Synchronous parity or ECC error on memory access, not on translation table walk
- 011001 SError interrupt, from a parity or ECC error on memory access
- 011101 Synchronous parity or ECC error on memory access on translation table walk, level 1
- 011110 Synchronous parity or ECC error on memory access on translation table walk, level 2
- 011111 Synchronous parity or ECC error on memory access on translation table walk, level 3
- 100001 Alignment fault

- 100010 Debug exception
 - 110000 TLB conflict abort
 - 110100 IMPLEMENTATION DEFINED fault (Lockdown fault)
 - 110101 IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault)
- All other values are reserved.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup* on page G4-4131.

Accessing the DFSR:

To access the DFSR:

MRC p15,0,<Rt>,c5,c0,0 ; Read DFSR into Rt
MCR p15,0,<Rt>,c5,c0,0 ; Write Rt to DFSR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0101 | 0000 | 000 |

G6.2.42 DTLBIALL, Data TLB Invalidate All

The DTLBIALL characteristics are:

Purpose

Invalidate all data TLB entries for the PL1&0 translation regime, subject to the Security state and Privilege level at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see [TLBIALL](#).

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

DTLBIALL is a 32-bit System instruction.

Field descriptions

DTLBIALL ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the DTLBIALL instruction:

The DTLBIALL instruction is executed as:

MCR p15,0,<Rt>,c8,c6,0 ; DTLBIALL operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 1000 | 0110 | 000 |

G6.2.43 DTLBIASID, Data TLB Invalidate by ASID match

The DTLBIASID characteristics are:

Purpose

Invalidate data TLB entries for stage 1 of the PL1&0 translation regime that match the given ASID, subject to the Security state at which the instruction is executed.

If this operation is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see [TLBIASID](#).

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

DTLBIASID is a 32-bit System instruction.

Field descriptions

The DTLBIASID input value bit assignments are:

Bits [31:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries for non-global pages that match the ASID values will be affected by this operation.

Executing the DTLBIASID instruction:

The DTLBIASID instruction is executed as:

MCR p15,0,<Rt>,c8,c6,2 ; DTLBIASID operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1000 | 0110 | 010 |

G6.2.44 DTLBIMVA, Data TLB Invalidate by VA

The DTLBIMVA characteristics are:

Purpose

Invalidate data TLB entries for stage 1 of the PL1&0 translation regime that match the given VA and ASID, subject to the Security state at which the instruction is executed.

If this instruction is executed at Secure EL1 in AArch32 when EL3 is using AArch64, it only affects TLB entries related to the Secure EL1 translation regime.

For details of the scope of this instruction see [TLBIMVA](#).

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TTLB==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T8==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T8==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

There are no configuration notes.

Attributes

DTLBIMVA is a 32-bit System instruction.

Field descriptions

The DTLBIMVA input value bit assignments are:

VA, bits [31:12]

Virtual address to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Bits [11:8]

Reserved, RES0.

ASID, bits [7:0]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

Executing the DTLBIMVA instruction:

The DTLBIMVA instruction is executed as:

MCR p15,0,<Rt>,c8,c6,1 ; DTLBIMVA operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1000 | 0110 | 001 |

G6.2.45 ELR_hyp, Exception Link Register (Hyp mode)

The ELR_hyp characteristics are:

Purpose

When taking an exception to Hyp mode, holds the address to return to.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

There are no traps or enables affecting this register.

Configurations

AArch32 System register ELR_hyp is architecturally mapped to AArch64 System register [ELR_EL2](#).

On a reset into an Exception level that is using AArch32 ELR_hyp is UNKNOWN.

Attributes

ELR_hyp is a 32-bit register.

Field descriptions

The ELR_hyp bit assignments are:

Bits [31:0]

Return address.

Accessing the ELR_hyp:

To access the ELR_hyp:

MRS <Rd>, ELR_hyp ; Read ELR_hyp into Rd
 MSR ELR_hyp, <Rd> ; Write Rd to ELR_hyp

Register access is encoded as follows:

| m | m1 | R |
|----------|-----------|----------|
| 1 | 1110 | 0 |

G6.2.46 FCSEIDR, FCSE Process ID register

The FCSEIDR characteristics are:

Purpose

Identifies whether the Fast Context Switch Extension (FCSE) is implemented.

In ARMv8, the FCSE is not implemented, so this register is RAZ/WI. Software can access this register to determine that the implementation does not include the FCSE.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RW | RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RW | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T13==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T13==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Attributes

FCSEIDR is a 32-bit register.

Field descriptions

The FCSEIDR bit assignments are:

Bits [31:0]

Reserved, RAZ/WI. Hardware must implement this as RAZ/WI. Software must not rely on this property as the behavior of reserved values might change in a future revision of the architecture.

Accessing the FCSEIDR:

To access the FCSEIDR:

MRC p15,0,<Rt>,c13,c0,0 ; Read FCSEIDR into Rt
MCR p15,0,<Rt>,c13,c0,0 ; Write Rt to FCSEIDR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 1101 | 0000 | 000 |

G6.2.47 FPEXC, Floating-Point Exception Control register

The FPEXC characteristics are:

Purpose

Provides a global enable for the implemented Advanced SIMD and floating-point functionality, and reports floating-point status information.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|-----------|-----------|----------------|----------------|
| - | - | Config-RW | Config-RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----------|-----------|
| - | Config-RW | Config-RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `CPACR.cp10==00`, accesses to this register from PL1 are UNDEFINED.
- If `NSACR.cp10==0`, Non-secure accesses to this register from EL1 and EL2 are UNDEFINED.
- If `CPTR_EL2.TFP==1`, Non-secure accesses to this register from EL1 are trapped to EL2.
- If `CPTR_EL3.TFP==1`, accesses to this register from EL1 and EL2 are trapped to EL3.
- If `HCPTR.TCP10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HCPTR.TCP10==1`, Non-secure accesses to this register from EL2 are UNDEFINED.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register FPEXC is architecturally mapped to AArch64 System register [FPEXC32_EL2](#).

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into an Exception level that is using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPEXC is a 32-bit register.

Field descriptions

The FPEXC bit assignments are:

EX, bit [31]

Exception bit. In ARMv8, this bit is RAZ/WI.

EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the [FPEXC](#) or [FPSID](#).
 - VMRS accesses from the [FPEXC](#), [FPSID](#), [MVFR0](#), [MVFR1](#), or [MVFR2](#).
- 0 Accesses to the [FPSCR](#), and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.
- 1 This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of floating-point and Advanced SIMD instructions in AArch32 state can be disabled or trapped by the following controls:

- [CPACR](#).cp10, or, if executing at EL0, [CPACR_EL1](#).FPEN.
- [FPEXC](#).EN.
- If executing in Non-secure state:
 - [HCPTR](#).TCP10, or if EL2 is using AArch64, [CPTR_EL2](#).TFP.
 - [NSACR](#).cp10, or if EL3 is using AArch64, [CPTR_EL3](#).TFP.
- For Advanced SIMD instructions only:
 - [CPACR](#).ASEDIS.
 - If executing in Non-secure state, [HCPTR](#).TASE and [NSACR](#).NSTRCDIS.

See the descriptions of the controls for more information.

———— Note —————

When executing at EL0 using AArch32 with EL1 using AArch64, the PE behaves as if the value of [FPEXC](#).EN bit is 1.

When this register has an architecturally-defined reset value, this field resets to 0.

DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning `TRUE`. This field also indicates whether the [FPEXC](#).TFV field is valid.

The meaning of this bit is:

- 0 The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function ExecutingCP10or11Instr(). If FPEXC.TFV is RW then FPEXC.TFV is invalid and UNKNOWN. If FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.
- 1 The exception was generated during the execution of an allocated encoding. FPEXC.TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the FPSCR.{Stride, Len} fields as RAZ, this bit is RES0.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

FP2V, bit [28]

FPINST2 instruction valid bit. In ARMv8, this bit is RES0.

VV, bit [27]

VECITR valid bit. In ARMv8, this bit is RES0.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC.DEX is 1. When valid, it indicates the cause of the exception and therefore whether the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are valid.

- 0 The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR.{Stride, Len} was non-zero. If the FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} bits are RW then they are invalid and UNKNOWN.
- 1 FPEXC.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

On an implementation that supports the trapping of floating-point exceptions and implements FPSCR.{Stride, Len} as RAZ, this bit is RAO/WI.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. In ARMv8, this field is RES1.

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

- 0 Input denormal exception has not occurred.
- 1 Input denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

0 Inexact exception has not occurred.

1 Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

0 Underflow exception has not occurred.

1 Underflow exception has occurred.

Underflow trapped exceptions can occur only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

0 Overflow exception has not occurred.

1 Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

DZE, bit [1]

Divide-by-zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide-by-zero exception occurred while FPSCR.DZE was 1:

0 Divide-by-zero exception has not occurred.

1 Divide-by-zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

IOF, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

- 0 Invalid Operation exception has not occurred.
- 1 Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

On an implementation that does not support the trapping of floating-point exceptions this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Accessing the FPEXC:

To access the FPEXC:

VMRS <Rt>, FPEXC ; Read FPEXC into Rt
VMSR FPEXC, <Rt> ; Write Rt to FPEXC

Register access is encoded as follows:

| |

| spec_reg |
| 1000 |

G6.2.48 FPSCR, Floating-Point Status and Control Register

The FPSCR characteristics are:

Purpose

Provides floating-point system status information and control.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|-----------|-----------|-----------|-----------|----------------|----------------|
| Config-RW | Config-RW | Config-RW | Config-RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----------|-----------|-----------|
| Config-RW | Config-RW | Config-RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `CPACR.cp10==00`, accesses to this register from PL0 and PL1 are UNDEFINED.
- If `CPACR.cp10==01`, accesses to this register from PL0 are UNDEFINED.
- If `NSACR.cp10==0`, Non-secure accesses to this register from EL0, EL1, and EL2 are UNDEFINED.
- If `CPACR_EL1.FPEN==00`, accesses to this register from PL0 are trapped to EL1.
- If `CPACR_EL1.FPEN==01`, accesses to this register from PL0 are trapped to EL1.
- If `CPACR_EL1.FPEN==10`, accesses to this register from PL0 are trapped to EL1.
- If `CPTR_EL2.TFP==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to EL2.
- If `CPTR_EL3.TFP==1`, accesses to this register from EL0, EL1, and EL2 are trapped to EL3.
- If `HCPTR.TCP10==1`, Non-secure accesses to this register from EL0 and EL1 are trapped to Hyp mode.
- If `HCPTR.TCP10==1`, Non-secure accesses to this register from EL2 are UNDEFINED.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

The named fields in this register map to the equivalent fields in the AArch64 [FPCR](#) and [FPSR](#).

It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

FPSCR is a 32-bit register.

Field descriptions

The FPSCR bit assignments are:

N, bit [31]

Negative condition flag. This is updated by floating-point comparison operations.

Z, bit [30]

Zero condition flag. This is updated by floating-point comparison operations.

C, bit [29]

Carry condition flag. This is updated by floating-point comparison operations.

V, bit [28]

Overflow condition flag. This is updated by floating-point comparison operations.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

AHP, bit [26]

Alternative half-precision control bit:

- 0 IEEE half-precision format selected.
- 1 Alternative half-precision format selected.

DN, bit [25]

Default NaN mode control bit:

- 0 NaN operands propagate through to the output of a floating-point operation.
- 1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Default NaN setting, regardless of the value of the DN bit.

FZ, bit [24]

Flush-to-zero mode control bit:

- 0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.
- 1 Flush-to-zero mode enabled.

The value of this bit only controls scalar floating-point arithmetic. Advanced SIMD arithmetic always uses the Flush-to-zero setting, regardless of the value of the FZ bit.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:

- 00 Round to Nearest (RN) mode
- 01 Round towards Plus Infinity (RP) mode
- 10 Round towards Minus Infinity (RM) mode
- 11 Round towards Zero (RZ) mode.

The specified rounding mode is used by almost all scalar floating-point instructions. Advanced SIMD arithmetic always uses the Round to Nearest setting, regardless of the value of the RMode bits.

Stride, bits [21:20]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

Bit [19]

Reserved, RES0.

Len, bits [18:16]

It is IMPLEMENTATION DEFINED whether this field is RW or RAZ.

If this field is RW and is set to a value other than zero, some floating-point instruction encodings are UNDEFINED. The instruction pseudocode identifies these instructions.

ARM strongly recommends that software never sets this field to a value other than zero.

The value of this field is ignored when processing Advanced SIMD instructions.

IDE, bit [15]

Input Denormal exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IDC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IDC bit. The trap handling software can decide whether to set the IDC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IXC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IXC bit. The trap handling software can decide whether to set the IXC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

UFE, bit [11]

Underflow exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the UFC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the UFC bit. The trap handling software can decide whether to set the UFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

OFE, bit [10]

Overflow exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the OFC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the OFC bit. The trap handling software can decide whether to set the OFC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

DZE, bit [9]

Division by Zero exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the DZC bit is set to 1.
- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the DZC bit. The trap handling software can decide whether to set the DZC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IOE, bit [8]

Invalid Operation exception trap enable. Possible values are:

- 0 Untrapped exception handling selected. If the floating-point exception occurs then the IOC bit is set to 1.

- 1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the IOC bit. The trap handling software can decide whether to set the IOC bit to 1.

This bit is RW only if the implementation supports the trapping of floating-point exceptions. In an implementation that does not support floating-point exception trapping, this bit is RES0.

When this bit is RW, it applies only to floating-point operations. Advanced SIMD operations always use untrapped floating-point exception handling in AArch32 state.

IDC, bit [7]

Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IDE bit.

Advanced SIMD instructions set this bit if the Input Denormal exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IDE bit.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IXE bit.

Advanced SIMD instructions set this bit if the Inexact exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IXE bit.

UFC, bit [3]

Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the UFE bit.

Advanced SIMD instructions set this bit if the Underflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the UFE bit.

OFC, bit [2]

Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the OFE bit.

Advanced SIMD instructions set this bit if the Overflow exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the OFE bit.

DZC, bit [1]

Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the DZE bit.

Advanced SIMD instructions set this bit if the Division by Zero exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the DZE bit.

IOC, bit [0]

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How VFP instructions update this bit depends on the value of the IOE bit.

Advanced SIMD instructions set this bit if the Invalid Operation exception occurs in one or more of the floating-point calculations performed by the instruction, regardless of the value of the IOE bit.

Accessing the FPSCR:

To access the FPSCR:

VMRS <Rt>, FPSCR ; Read FPSCR into Rt
VMSR FPSCR, <Rt> ; Write Rt to FPSCR

Register access is encoded as follows:

spec_reg

0001

G6.2.49 FPSID, Floating-Point System ID register

The FPSID characteristics are:

Purpose

Provides top-level information about the floating-point implementation.

This register largely duplicates information held in the [MIDR](#). ARM deprecates use of it.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|-----------|-----------|----------------|----------------|
| - | - | Config-RW | Config-RW | RW | RW |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----------|-----------|
| - | Config-RW | Config-RW |

When access to this register is permitted, write accesses are ignored.

This register largely duplicates information held in the [MIDR](#). ARM deprecates use of it.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [CPACR.cp10==00](#), accesses to this register from PL1 are UNDEFINED.
- If [NSACR.cp10==0](#), Non-secure accesses to this register from EL1 and EL2 are UNDEFINED.
- If [CPTR_EL2.TFP==1](#), Non-secure accesses to this register from EL1 are trapped to EL2.
- If [CPTR_EL3.TFP==1](#), accesses to this register from EL1 and EL2 are trapped to EL3.
- If [HCPTR.TCP10==1](#), Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If [HCPTR.TCP10==1](#), Non-secure accesses to this register from EL2 are UNDEFINED.
- If [HCR.TID0==1](#), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HCR_EL2.TID0==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

Attributes

FPSID is a 32-bit register.

Field descriptions

The FPSID bit assignments are:

Implementer, bits [31:24]

Implementer codes are the same as those used for the [MIDR](#).

For an implementation by ARM this field is 0x41, the ASCII code for A.

SW, bit [23]

Software bit. Defined values are:

0 The implementation provides a hardware implementation of the floating-point instructions.

1 The implementation supports only software emulation of the floating-point instructions.

In ARMv8-A the only permitted value is 0.

Subarchitecture, bits [22:16]

Subarchitecture version number. For an implementation by ARM, defined values are:

0000000 VFPv1 architecture with an IMPLEMENTATION DEFINED subarchitecture.

0000001 VFPv2 architecture with Common VFP subarchitecture v1.

0000010 VFPv3 architecture, or later, with Common VFP subarchitecture v2. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.

0000011 VFPv3 architecture, or later, with Null subarchitecture. The entire floating-point implementation is in hardware, and no software support code is required. The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers. This value can be used only by an implementation that does not support the trap enable bits in the [FPSCR](#).

0000100 VFPv3 architecture, or later, with Common VFP subarchitecture v3, and support for trap enable bits in [FPSCR](#). The VFP architecture version is indicated by the [MVFR0](#) and [MVFR1](#) registers.

For a subarchitecture designed by ARM the most significant bit of this field, register bit[22], is 0. Values with a most significant bit of 0 that are not listed here are reserved.

When the subarchitecture designer is not ARM, the most significant bit of this field, register bit[22], must be 1. Each implementer must maintain its own list of subarchitectures it has designed, starting at subarchitecture version number 0x40.

In ARMv8-A the permitted values are 0000011 and 0000100.

PartNum, bits [15:8]

An IMPLEMENTATION DEFINED part number for the floating-point implementation, assigned by the implementer.

Variant, bits [7:4]

An IMPLEMENTATION DEFINED variant number. Typically, this field distinguishes between different production variants of a single product.

Revision, bits [3:0]

An IMPLEMENTATION DEFINED revision number for the floating-point implementation.

Accessing the FPSID:

To access the FPSID:

VMRS <Rt>, FPSID ; Read FPSID into Rt
VMSR FPSID, <Rt> ; Write Rt to FPSID

Register access is encoded as follows:

spec_reg

0000

G6.2.50 HACR, Hyp Auxiliary Configuration Register

The HACR characteristics are:

Purpose

Controls trapping to Hyp mode of IMPLEMENTATION DEFINED aspects of Non-secure EL1 or EL0 operation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HACR is architecturally mapped to AArch64 System register [HACR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACR is a 32-bit register.

Field descriptions

The HACR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACR:

To access the HACR:

MRC p15,4,<Rt>,c1,c1,7 ; Read HACR into Rt
MCR p15,4,<Rt>,c1,c1,7 ; Write Rt to HACR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0001 | 0001 | 111 |

G6.2.51 HACTLR, Hyp Auxiliary Control Register

The HACTLR characteristics are:

Purpose

Controls IMPLEMENTATION DEFINED features of Hyp mode operation.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HACTLR is architecturally mapped to AArch64 System register [ACTLR_EL2\[31:0\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACTLR is a 32-bit register.

Field descriptions

The HACTLR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACTLR:

To access the HACTLR:

MRC p15,4,<Rt>,c1,c0,1 ; Read HACTLR into Rt
MCR p15,4,<Rt>,c1,c0,1 ; Write Rt to HACTLR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0001 | 0000 | 001 |

G6.2.52 HACTLR2, Hyp Auxiliary Control Register 2

The HACTLR2 characteristics are:

Purpose

Provides additional space to the HACTLR register to hold IMPLEMENTATION DEFINED trap functionality.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HACTLR2 is architecturally mapped to AArch64 System register [ACTLR_EL2\[63:32\]](#).

It is IMPLEMENTATION DEFINED whether this register is implemented, or whether it causes UNDEFINED exceptions when accessed.

The implementation of this register can be detected by examining bits [7:4] of the [ID_MMFR4/ID_MMFR4_EL1](#) register.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HACTLR2 is a 32-bit register.

Field descriptions

The HACTLR2 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HACTLR2:

To access the HACTLR2:

MRC p15,4,<Rt>,c1,c0,3 ; Read HACTLR2 into Rt
MCR p15,4,<Rt>,c1,c0,3 ; Write Rt to HACTLR2

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0001 | 0000 | 011 |

G6.2.53 HADFSR, Hyp Auxiliary Data Fault Status Register

The HADFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Data Abort exceptions taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HADFSR is architecturally mapped to AArch64 System register [AFSR0_EL2](#).

This is an optional register. An implementation that does not require this register can implement it as RES0.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HADFSR is a 32-bit register.

Field descriptions

The HADFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HADFSR:

To access the HADFSR:

MRC p15,4,<Rt>,c5,c1,0 ; Read HADFSR into Rt
MCR p15,4,<Rt>,c5,c1,0 ; Write Rt to HADFSR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0101 | 0001 | 000 |

G6.2.54 HAIFSR, Hyp Auxiliary Instruction Fault Status Register

The HAIFSR characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED syndrome information for Prefetch Abort exceptions taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HAIFSR is architecturally mapped to AArch64 System register `AFSR1_EL2`.

This is an optional register. An implementation that does not require this register can implement it as `RES0`.

If EL2 is not implemented, this register is `RES0` from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HAIFSR is a 32-bit register.

Field descriptions

The HAIFSR bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HAIFSR:

To access the HAIFSR:

MRC p15,4,<Rt>,c5,c1,1 ; Read HAIFSR into Rt
MCR p15,4,<Rt>,c5,c1,1 ; Write Rt to HAIFSR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0101 | 0001 | 001 |

G6.2.55 HMAIIR0, Hyp Auxiliary Memory Attribute Indirection Register 0

The HMAIIR0 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by [HMAIIR0](#). These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in [HMAIIR0](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HMAIIR0 is architecturally mapped to AArch64 System register [AMAIR_EL2\[31:0\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIIR0 is a 32-bit register.

Field descriptions

The HMAIIR0 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HAMAIRO:

To access the HAMAIRO:

MRC p15,4,<Rt>,c10,c3,0 ; Read HAMAIRO into Rt
MCR p15,4,<Rt>,c10,c3,0 ; Write Rt to HAMAIRO

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1010 | 0011 | 000 |

G6.2.56 HMAIR1, Hyp Auxiliary Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory attribute encodings defined by [HMAIR1](#). These IMPLEMENTATION DEFINED attributes can only provide additional qualifiers for the memory attribute encodings, and cannot change the memory attributes defined in [HMAIR1](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

If an implementation does not provide any IMPLEMENTATION DEFINED memory attributes, this register is RES0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HMAIR1 is architecturally mapped to AArch64 System register [AMAIR_EL2\[63:32\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

IMPLEMENTATION DEFINED, bits [31:0]

IMPLEMENTATION DEFINED.

Accessing the HAMAIR1:

To access the HAMAIR1:

MRC p15,4,<Rt>,c10,c3,1 ; Read HAMAIR1 into Rt
MCR p15,4,<Rt>,c10,c3,1 ; Write Rt to HAMAIR1

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1010 | 0011 | 001 |

G6.2.57 HCPTR, Hyp Architectural Feature Trap Register

The HCPTR characteristics are:

Purpose

Controls:

- Trapping to Hyp mode of Non-secure access, at EL1 or EL0, to trace, and to Advanced SIMD and floating-point functionality.
- Hyp mode access to trace, and to Advanced SIMD and floating-point functionality.

Note

Accesses to this functionality:

- From Non-secure modes other than Hyp mode are also affected by settings in the [CPACR](#) and [NSACR](#).
- From Hyp mode are also affected by settings in the [NSACR](#).

Exceptions generated by the [CPACR](#) and [NSACR](#) controls are higher priority than those generated by the HCPTR controls.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [CPTR_EL3.TCPAC](#)==1, accesses to this register from EL2 are trapped to EL3.
- If [HSTR.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If [HSTR_EL2.T1](#)==1, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HCPTR is architecturally mapped to AArch64 System register [CPTR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

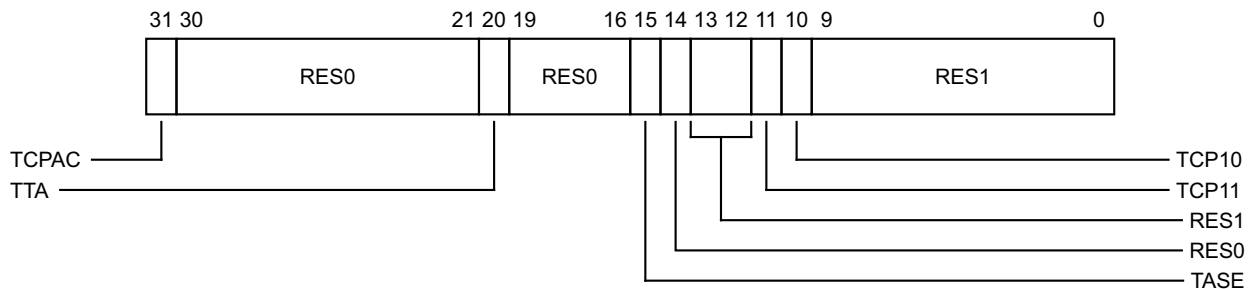

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCPTR is a 32-bit register.

Field descriptions

The HCPTR bit assignments are:

TCPAC, bit [31]

Traps Non-secure EL1 accesses to the [CPACR](#) to Hyp mode.

- 0 This control has no effect on Non-secure EL1 accesses to the [CPACR](#).
- 1 Non-secure EL1 accesses to the [CPACR](#) are trapped to Hyp mode.

———— Note ————

The [CPACR](#) is not accessible at EL0.

When this register has an architecturally-defined reset value, this field resets to 0.

Bits [30:21]

Reserved, RES0.

TTA, bit [20]

Traps Non-secure System register accesses to all implemented trace registers to Hyp mode.

- 0 This control has no effect on Non-secure System register accesses to trace registers.
- 1 Any Non-secure System register access to an implemented trace register is trapped to Hyp mode, unless the access is trapped to EL1 by a [CPACR](#) or [NSACR](#) control, or the access is from Non-secure EL0 and the definition of the register in the appropriate trace architecture specification indicates that the register is not accessible from EL0. A trapped instruction generates:
 - A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.
 - An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode.

If the implementation does not include a trace macrocell, or does not include a System register interface to the trace macrocell registers, it is IMPLEMENTATION DEFINED whether this bit:

- Is RES0.
- Is RES1.
- Can be written from Hyp mode, and from Secure Monitor mode when [SCR.NS](#) is 1.

If EL3 is implemented and is using AArch32, and the value of [NSACR.NSTRCDIS](#) is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

———— Note ————

- The ETMv4 architecture does not permit EL0 to access the trace registers. If the implementation includes an ETMv4 implementation, EL0 accesses to the trace registers are UNDEFINED, and a resulting Undefined Instruction exception is higher priority than a HCPTR.TTA Hyp Trap exception.

- The architecture does not provide traps on trace register accesses through the optional memory-mapped external debug interface.

System register accesses to the trace registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [19:16]

Reserved, RES0.

TASE, bit [15]

Traps Non-secure execution of Advanced SIMD instructions to Hyp mode when the value of HCPTR.TCP10 is 0.

- | | |
|---|--|
| 0 | This control has no effect on Non-secure execution of Advanced SIMD instructions. |
| 1 | When the value of HCPTR.TCP10 is 0, any attempt to execute an Advanced SIMD instruction in Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates: <ul style="list-style-type: none">• A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1.• An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode. |

When the value of HCPTR.TCP10 is 1, the value of this field is ignored.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1. Otherwise, it is IMPLEMENTATION DEFINED whether this field is implemented as a RW field. If it is not implemented as a RW field, then it is RAZ/WI.

If EL3 is implemented and is using AArch32, and the value of NSACR.NSASEDIS is 1, in Non-secure state this field behaves as RAO/WI, regardless of its actual value. This applies even if the field is implemented as RAZ/WI.

For the list of instructions affected by this field, see [Controls of Advanced SIMD operation that do not apply to floating-point operation on page E1-2306](#).

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [14]

Reserved, RES0.

Bits [13:12]

Reserved, RES1.

TCP11, bit [11]

The value of this field is ignored. If this field is programmed with a different value to the TCP10 bit then this field is UNKNOWN on a direct read of the HCPTR.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of NSACR.cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

TCP10, bit [10]

Trap Non-secure accesses to Advanced SIMD and floating-point functionality to Hyp mode:

- | | |
|---|--|
| 0 | This control has no effect on Non-secure accesses to Advanced SIMD and floating-point functionality. |
| 1 | Any attempted access to Advanced SIMD and floating-point functionality from Non-secure state is trapped to Hyp mode, unless it is trapped to EL1 by a CPACR or NSACR control. A trapped instruction generates: <ul style="list-style-type: none"> • A Hyp Trap exception, if the exception is taken from Non-secure EL0 or EL1. • An Undefined Instruction exception taken to Hyp mode, if the exception is taken from Hyp mode. |

The Advanced SIMD and floating-point features controlled by these fields are:

- Execution of any floating-point or Advanced SIMD instruction.
- Any access to the Advanced SIMD and floating-point registers D0-D31 and their views as S0-S31 and Q0-Q15.
- Any access to the [FPSCR](#), [FPSID](#), [MVFRO](#), [MVFR1](#), [MVFR2](#), or [FPEXC](#) System registers.

If the implementation does not include Advanced SIMD and floating-point functionality, this field is RES1.

If EL3 is implemented and is using AArch32, and the value of [NSACR](#).cp10 is 0, in Non-secure state this field behaves as RAO/WI, regardless of its actual value.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bits [9:0]

Reserved, RES1.

Accessing the HCPTR:

To access the HCPTR:

MRC p15,4,<Rt>,c1,c1,2 ; Read HCPTR into Rt
MCR p15,4,<Rt>,c1,c1,2 ; Write Rt to HCPTR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0001 | 0001 | 010 |

G6.2.58 HCR, Hyp Configuration Register

The HCR characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various Non-secure operations are trapped to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HCR is architecturally mapped to AArch64 System register [HCR_EL2\[31:0\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR is a 32-bit register.

Field descriptions

The HCR bit assignments are:

Bit [31]

Reserved, RES0.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps Non-secure EL1 reads of the virtual memory control registers to Hyp mode. The registers for which read accesses are trapped are as follows:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIRO](#), [AMAIR1](#), [CONTEXTIDR](#).

- 0 This control has no effect on Non-secure EL1 read accesses to Virtual Memory controls.
- 1 Non-secure EL1 read accesses to the specified Virtual Memory controls are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

HCD, bit [29]

HVC instruction disable. Disables Non-secure state execution of HVC instructions.

- 0 HVC instruction execution is enabled at EL2 and Non-secure EL1.
- 1 HVC instructions are UNDEFINED at EL2 and Non-secure EL1. The Undefined Instruction exception is taken to the Exception level at which the HVC instruction is executed.

Note

HVC instructions are always UNDEFINED at EL0.

This bit is only implemented if EL3 is not implemented. Otherwise, it is RES0.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

Bit [28]

Reserved, RES0.

TGE, bit [27]

Trap General Exceptions, from Non-secure EL0.

- 0 This control has no effect on execution at EL0.
- 1 When the value of [SCR.NS](#) is 0, this control has no effect on execution at EL0.
When the value of [SCR.NS](#) is 1, then:
- All exceptions that would be routed to EL1 are routed to EL2.
 - The [SCTLR.M](#) bit is treated as being 0 for all purposes other than returning the result of a direct read of [SCTLR](#).
 - The [HCR.{FMO, IMO, AMO}](#) bits are treated as being 1 for all purposes other than returning the result of a direct read of [HCR](#).
 - All virtual interrupts are disabled.
 - Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled.
 - An exception return to EL1 is treated as an illegal exception return.
 - Monitor mode execution of an MSR or CPS instruction that changes [CPSR.M](#) to a Non-secure EL1 mode is an illegal change to [PSTATE.M](#). For more information see [Illegal changes to PSTATE.M on page G1-3809](#).

Also, when [HCR.TGE](#) is 1:

- If EL3 is using AArch32, an attempt to change from a Secure PL1 mode to a Non-secure EL1 mode by changing [SCR.NS](#) from 0 to 1 results in [SCR.NS](#) remaining as 0.
- The [HDCR.{TDRA, TDOSA, TDA, TDE}](#) bits are ignored and treated as being 1 other than for the purpose of a direct read of [HDCR](#).

In the following cases the field resets to 0:

- The PE resets into EL3 with EL3 using AArch32.
- The PE resets into EL2 with EL2 using AArch32.

Otherwise, the field reset value is architecturally UNKNOWN.

When this register has an architecturally-defined reset value, this field resets to 0.

TVM, bit [26]

Trap Virtual Memory controls. Traps Non-secure EL1 writes to the virtual memory control registers to Hyp mode. The registers for which write accesses are trapped are as follows:

[SCTLR](#), [TTBR0](#), [TTBR1](#), [TTBCR](#), [DACR](#), [DFSR](#), [IFSR](#), [DFAR](#), [IFAR](#), [ADFSR](#), [AIFSR](#), [PRRR](#), [NMRR](#), [MAIR0](#), [MAIR1](#), [AMAIR0](#), [AMAIR1](#), [CONTEXTIDR](#).

- 0 This control has no effect on Non-secure EL1 write accesses to EL1 virtual memory control registers.
- 1 Non-secure EL1 write accesses to EL1 virtual memory control registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps Non-secure EL1 execution of a TLBI instruction to Hyp mode. This applies to the following instructions:

[TLBIALLIS](#), [TLBIMVAIS](#), [TLBIASIDIS](#), [TLBIMVAAIS](#), [TLBIMVALIS](#), [TLBIMVAALIS](#),
[ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [TLBIALL](#),
[TLBIMVA](#), [TLBIASID](#), [TLBIMVAA](#), [TLBIMVAL](#), [TLBIMVAAL](#)

- 0 This control has no effect on Non-secure EL1 accesses to TLB maintenance instructions.
- 1 Non-secure EL1 accesses to TLB maintenance instructions are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

[ICIMVAU](#), [ICIALLU](#), [ICIALLUI](#), [DCCMVAU](#).

———— **Note** —————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- | | |
|---|--|
| 0 | This control has no effect on the execution of cache maintenance instructions. |
| 1 | Non-secure EL1 execution of the specified instructions is trapped to Hyp mode. |

When this register has an architecturally-defined reset value, this field resets to 0.

TPC, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency. Traps Non-secure EL1 execution of those cache maintenance instructions to Hyp mode. This applies to the following instructions:

[DCIMVAC](#), [DCCIMVAC](#), [DCCMVAC](#).

———— **Note** —————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- | | |
|---|--|
| 0 | This control has no effect on the execution of cache maintenance instructions. |
| 1 | Non-secure execution of the specified instructions is trapped to Hyp mode. |

When this register has an architecturally-defined reset value, this field resets to 0.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps Non-secure EL1 execution of those cache maintenance instructions by set/way to Hyp mode. This applies to the following instructions:

[DCISW](#), [DCCSW](#), [DCCISW](#).

———— **Note** —————

An Undefined Instruction exception generated at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

- | | |
|---|--|
| 0 | This control has no effect on the execution of cache maintenance instructions. |
| 1 | Non-secure execution of the specified instructions is trapped to Hyp mode. |

When this register has an architecturally-defined reset value, this field resets to 0.

TAC, bit [21]

Trap Auxiliary Control Registers. Traps Non-secure EL1 accesses to the Auxiliary Control Registers to Hyp mode, from both Execution states. This applies to the following register accesses:

[ACTLR](#) and, if implemented, [ACTLR2](#).

- | | |
|---|---|
| 0 | This control has no effect on Non-secure EL1 accesses to the Auxiliary Control Registers. |
| 1 | Non-secure EL1 accesses to the specified registers are trapped to Hyp mode. |

When this register has an architecturally-defined reset value, this field resets to 0.

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps Non-secure EL1 accesses to the encodings for IMPLEMENTATION DEFINED System Registers to Hyp mode.

MCR and MRC instructions accessing the following encodings:

- All coproc==p15, CRn==c9, Opcode1 = {0-7}, CRm == {c0-c2, c5-c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c10, Opcode1 =={0-7}, CRm == {c0, c1, c4, c8}, opcode2 == {0-7}.
- All coproc==p15, CRn==c11, Opcode1=={0-7}, CRm == {c0-c8, c15}, opcode2 == {0-7}.

When HCR.TIDCP is set to 1, it is IMPLEMENTATION DEFINED whether any of this functionality accessed from Non-secure EL0 is trapped to Hyp mode. If it is not, it is UNDEFINED, and the PE takes an Undefined Instruction exception to Non-secure Undefined mode.

- 0 This control has no effect on Non-secure EL1 and EL0 accesses to the System register encodings for IMPLEMENTATION DEFINED functionality.
- 1 Non-secure EL1 accesses to the specified System register encodings for IMPLEMENTATION DEFINED functionality are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TSC, bit [19]

Trap SMC instructions. Traps Non-secure EL1 execution of SMC instructions to Hyp mode.

- 0 This control has no effect on execution of SMC instructions.
- 1 Any attempt to execute an SMC instruction at Non-secure EL1 is trapped to Hyp mode, regardless of the value of SCR.SCD.

The ARMv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

Note

- This trap is only implemented if the implementation includes EL3.
- SMC instructions are always UNDEFINED at PL0.
- This bit traps execution of the SMC instruction. It is not a routing control for the SMC exception. Hyp Trap exceptions and SMC exceptions have different preferred return addresses.

When this register has an architecturally-defined reset value, this field resets to 0.

TID3, bit [18]

Trap ID group 3. Traps Non-secure EL1 reads of the following registers to Hyp mode:

[ID_PFR0](#), [ID_PFR1](#), [ID_DFR0](#), [ID_AFR0](#), [ID_MMFR0](#), [ID_MMFR1](#), [ID_MMFR2](#), [ID_MMFR3](#), [ID_ISAR0](#), [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), [ID_ISAR5](#), [MVFR0](#), [MVFR1](#), [MVFR2](#), and [ID_MMFR4](#), except that if [ID_MMFR4](#) is implemented as RAZ/WI then it is IMPLEMENTATION DEFINED whether accesses to [ID_MMFR4](#) are trapped.

Also an MRC access to any of the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == {c3-c7}, opc2 == {0,1}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == 2.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {4,5}.

It is IMPLEMENTATION DEFINED whether this bit traps MRC accesses to the following encodings:

- coproc==p15, opc1 == 0, CRn == c0, CRm == c2, opc2 == 7.
- coproc==p15, opc1 == 0, CRn == c0, CRm == c3, opc2 == {3-7}.
- coproc==p15, opc1 == 0, CRn == c0, CRm == {c4, c6, c7}, opc2 == {2-7}.

- coproc==p15, opc1 == 0, CRn == c0, CRm == c5, opc2 == {2, 3, 6, 7}.
- 0 This control has no effect on Non-secure EL1 reads of the ID group 3 registers.
- 1 The specified Non-secure EL1 read accesses to ID group 3 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to Hyp mode:

- Non-secure EL1 and EL0 reads of the [CTR](#), [CCSIDR](#), [CLIDR](#), and [CSSELR](#).
- Non-secure EL1 and EL0 writes to the [CSSELR](#).

0 This control has no effect on Non-secure EL1 and EL0 accesses to the ID group 2 registers.

1 The specified Non-secure EL1 and EL0 accesses to ID group 2 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID1, bit [16]

Trap ID group 1. Traps Non-secure EL1 reads of the following registers to Hyp mode:

[TCMTR](#), [TLBTR](#), [REVIDR](#), [AIDR](#).

0 This control has no effect on Non-secure EL1 reads of the ID group 1 registers.

1 The specified Non-secure EL1 read accesses to ID group 1 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TID0, bit [15]

Trap ID group 0. Traps the following register accesses to Hyp mode:

- Non-secure EL1 reads of the [JIDR](#) and [FPSID](#).
- If the [JIDR](#) is RAZ from Non-secure EL0, Non-secure EL0 reads of the [JIDR](#).

———— Note —————

- It is IMPLEMENTATION DEFINED whether the [JIDR](#) is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0 then the Undefined Instruction exception takes precedence over this trap.
- The [FPSID](#) is not accessible at EL0.
- Writes to the [FPSID](#) are ignored, and not trapped by this control.

0 This control has no effect on Non-secure EL1 reads of the ID group 0 registers.

1 The specified Non-secure EL1 read accesses to ID group 0 registers are trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

TWE, bit [14]

Traps Non-secure EL0 and EL1 execution of WFE instructions to Hyp mode:

0 This control has no effect on the execution of WFE instructions at Non-secure EL0 or Non-secure EL1.

1 Any attempt to execute a WFE instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state, except that when the value of [SCTLR.nTWE](#) is 0, the trap of EL0 execution to Undefined mode takes precedence over this trap.

The attempted execution of a conditional WFE instruction is only trapped if the instruction passes its condition code check.

———— **Note** ————

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

TWI, bit [13]

Traps Non-secure EL0 and EL1 execution of WFI instructions to Hyp mode.

- | | |
|---|--|
| 0 | This control has no effect on the execution of WFI instructions at Non-secure EL1 or Non-secure EL0. |
| 1 | Any attempt to execute a WFI instruction at Non-secure EL0 or EL1 is trapped to Hyp mode, if the instruction would otherwise have caused the PE to enter a low-power state, except that when the value of SCTLR.nTWI is 0, the trap of EL0 execution to Undefined mode takes precedence over this trap. |

The attempted execution of a conditional WFI instruction is only trapped if the instruction passes its condition code check.

———— **Note** ————

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When this register has an architecturally-defined reset value, this field resets to 0.

DC, bit [12]

Default Cacheability.

- | | |
|---|--|
| 0 | This control has no effect on the Non-secure EL1&0 translation regime. |
| 1 | In Non-secure state: <ul style="list-style-type: none">• The SCTLR.M field behaves as 0 for all purposes other than a direct read of the value of the field.• The HCR.VM field behaves as 1 for all purposes other than a direct read of the value of the field.• The memory type produced by the first stage of the EL1&0 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate. |

This field has no effect on the EL2 and EL3 translation regimes.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from Non-secure EL1 or Non-secure EL0:

- | | |
|----|-----------------|
| 00 | No effect |
| 01 | Inner Shareable |
| 10 | Outer Shareable |
| 11 | Full system |

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When this register has an architecturally-defined reset value, this field resets to 0.

FB, bit [9]

Force broadcast. Causes the following instructions to be broadcast within the Inner Shareable domain when executed from Non-secure EL1:

[BPIALL](#), [TLBIALL](#), [TLBIMVA](#), [TLBIASID](#), [DTLBIALL](#), [DTLBIMVA](#), [DTLBIASID](#), [ITLBIALL](#), [ITLBIMVA](#), [ITLBIASID](#), [TLBIMVAA](#), [ICIALLU](#), [TLBIMVAL](#), [TLBIMVAAL](#).

- 0 This field has no effect on the operation of the specified instructions.
- 1 When one of the specified instruction is executed at Non-secure EL1, the instruction is broadcast within the Inner Shareable shareability domain.

When this register has an architecturally-defined reset value, this field resets to 0.

VA, bit [8]

Virtual SError interrupt exception.

- 0 This mechanism is not making a virtual SError interrupt pending.
- 1 A virtual SError interrupt is pending because of this mechanism.

The virtual SError interrupt is only enabled when the value of HCR.{TGE, AMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VI, bit [7]

Virtual IRQ exception.

- 0 This mechanism is not making a virtual IRQ pending.
- 1 A virtual IRQ is pending because of this mechanism.

The virtual IRQ is only enabled when the value of HCR.{TGE, IMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

VF, bit [6]

Virtual FIQ exception.

- 0 This mechanism is not making a virtual FIQ pending.
- 1 A virtual FIQ is pending because of this mechanism.

The virtual FIQ is only enabled when the value of HCR.{TGE, FMO} is {0, 1}.

The Guest OS cannot distinguish the virtual exception from the corresponding physical exception.

When this register has an architecturally-defined reset value, this field resets to 0.

AMO, bit [5]

SError interrupt Mask Override. When this bit is set to 1, it overrides the effect of [CPSR.A](#), and enables virtual exception signaling by the VA bit.

If the value of HCR.TGE is 0, then Virtual SError interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.AMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

IMO, bit [4]

IRQ Mask Override. When this bit is set to 1, it overrides the effect of [CPSR.I](#), and enables virtual exception signaling by the VI bit.

If the value of HCR.TGE is 0, then Virtual IRQ interrupts are enabled in the Non-secure state.

If the value of HCR.TGE is 1, then in Non-secure state the HCR.IMO bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

FMO, bit [3]

FIQ Mask Override. When this bit is set to 1, it overrides the effect of [CPSR.F](#), and enables virtual exception signaling by the VF bit.

If the value of [HCR.TGE](#) is 0, then Virtual FIQ interrupts are enabled in the Non-secure state.

If the value of [HCR.TGE](#) is 1, then in Non-secure state the [HCR.FMO](#) bit behaves as 1 for all purposes other than a direct read of the value of the bit.

When this register has an architecturally-defined reset value, this field resets to 0.

PTW, bit [2]

Protected Table Walk. In the Non-secure PL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs then the value of this bit determines the behavior:

0 The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.

1 The memory access generates a stage 2 Permission fault.

This field is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

SWIO, bit [1]

Set/Way Invalidation Override. Causes Non-secure EL1 execution of the data cache invalidate by set/way instructions to be treated as data cache clean and invalidate by set/way.

0 This control has no effect on the operation of data cache invalidate by set/way instructions.

1 Data cache invalidate by set/way instructions operate as data cache clean and invalidate by set/way.

When this bit is set to 1, [DCISW](#) is executed as [DCCISW](#).

As a result of changes to the behavior of [DCISW](#), this bit is redundant in ARMv8. This bit can be implemented as RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to 0.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the Non-secure EL1&0 translation regime. Possible values of this bit are:

0 Non-secure EL1&0 stage 2 address translation disabled.

1 Non-secure EL1&0 stage 2 address translation enabled.

If the [HCR.DC](#) bit is set to 1, then the behavior of the PE when executing in a Non-secure mode other than Hyp mode is consistent with [HCR.VM](#) being 1, regardless of the actual value of [HCR.VM](#), other than the value returned by an explicit read of [HCR.VM](#).

When the value of this bit is 1, data cache invalidate instructions executed at Non-secure EL1 operate as data cache clean and invalidate instructions. For the invalidate by set/way instruction this behavior applies regardless of the value of the [HCR.SWIO](#) bit.

This bit is permitted to be cached in a TLB.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HCR:

To access the HCR:

```
MRC p15,4,<Rt>,c1,c1,0 ; Read HCR into Rt
MCR p15,4,<Rt>,c1,c1,0 ; Write Rt to HCR
```

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0001 | 0001 | 000 |

G6.2.59 HCR2, Hyp Configuration Register 2

The HCR2 characteristics are:

Purpose

Provides additional configuration controls for virtualization.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HCR2 is architecturally mapped to AArch64 System register [HCR_EL2\[63:32\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HCR2 is a 32-bit register.

Field descriptions

The HCR2 bit assignments are:

Bits [31:7]

Reserved, RES0.

MIOCNCEN, bit [6]

Mismatched Inner/Outer Cacheable Non-Coherency Enable, for the Non-secure PL1&0 translation regime.

- 0 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there must be no loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.
- 1 For the Non-secure PL1&0 translation regime, for permitted accesses to a memory location that use a common definition of the Shareability and Cacheability of the location, there might be a loss of coherency if the Inner Cacheability attribute for those accesses differs from the Outer Cacheability attribute.

For more information see [Mismatched memory attributes](#) on page E2-2352.

The value of this field has no effect on translation regimes other than the Non-secure PL1&0 translation regime.

This field can be implemented as RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [5:2]

Reserved, RES0.

ID, bit [1]

Stage 2 Instruction access cacheability disable. For the Non-secure PL1&0 translation regime, when [HCR.VM==1](#), this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

- 0 This control has no effect on stage 2 of the Non-secure PL1&0 translation regime.
- 1 For the Non-secure PL1&0 translation regime, forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

CD, bit [0]

Stage 2 Data access cacheability disable. When [HCR.VM==1](#), this forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable for the Non-secure PL1&0 translation regime.

- 0 This control has no effect on stage 2 of the Non-secure PL1&0 translation regime for data accesses and translation table walks.
- 1 For the Non-secure PL1&0 translation regime, forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

This bit has no effect on the EL2 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HCR2:

To access the HCR2:

MRC p15,4,<Rt>,c1,c1,4 ; Read HCR2 into Rt
MCR p15,4,<Rt>,c1,c1,4 ; Write Rt to HCR2

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0001 | 0001 | 100 |

G6.2.60 HDFAR, Hyp Data Fault Address Register

The HDFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Data Abort exception that is taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Any execution in a Non-secure EL1 mode, or in Secure state, makes the HDFAR UNKNOWN.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T6==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T6==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HDFAR is architecturally mapped to AArch64 System register [FAR_EL2\[31:0\]](#).

AArch32 System register HDFAR is architecturally mapped to AArch32 System register [DFAR \(S\)](#) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HDFAR is a 32-bit register.

Field descriptions

The HDFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Data Abort exception taken to Hyp mode.

On a Prefetch Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 mode, or in Secure state, makes this register UNKNOWN.

Accessing the HDFAR:

To access the HDFAR:

MRC p15,4,<Rt>,c6,c0,0 ; Read HDFAR into Rt

MCR p15,4,<Rt>,c6,c0,0 ; Write Rt to HDFAR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0110 | 0000 | 000 |

G6.2.61 HIFAR, Hyp Instruction Fault Address Register

The HIFAR characteristics are:

Purpose

Holds the virtual address of the faulting address that caused a synchronous Prefetch Abort exception that is taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Any execution in a Non-secure EL1 mode, or in Secure state, makes the HIFAR UNKNOWN.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T6==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T6==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HIFAR is architecturally mapped to AArch64 System register [FAR_EL2\[63:32\]](#).

AArch32 System register HIFAR is architecturally mapped to AArch32 System register [IFAR \(S\)](#) when EL2 is implemented.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HIFAR is a 32-bit register.

Field descriptions

The HIFAR bit assignments are:

Bits [31:0]

VA of faulting address of synchronous Prefetch Abort exception taken to Hyp mode.

On a Data Abort exception, this register is UNKNOWN.

Any execution in a Non-secure EL1 mode, or in Secure state, makes this register UNKNOWN.

Accessing the HIFAR:

To access the HIFAR:

MRC p15,4,<Rt>,c6,c0,2 ; Read HIFAR into Rt

MCR p15,4,<Rt>,c6,c0,2 ; Write Rt to HIFAR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0110 | 0000 | 010 |

G6.2.62 HMAIR0, Hyp Memory Attribute Indirection Register 0

The HMAIR0 characteristics are:

Purpose

Along with [HMAIR1](#), provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:

- When AttrIndx[2] is 0, HMAIR0 is used.
- When AttrIndx[2] is 1, [HMAIR1](#) is used.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 0 selects HMAIR0.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HMAIR0 is architecturally mapped to AArch64 System register [MAIR_EL2\[31:0\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR0 is a 32-bit register.

Field descriptions

The HMAIR0 bit assignments are:

When $TTBCR.EAE=1$:

Attr<n>, bits [8n+7:8n], for n = 0 to 3

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 0000 | Device memory. See encoding of Attr<n>[3:0] for the type of Device memory. |
| 00RW, RW not 00 | Normal Memory, Outer Write-Through transient |
| 0100 | Normal Memory, Outer Non-cacheable |
| 01RW, RW not 00 | Normal Memory, Outer Write-Back transient |
| 10RW | Normal Memory, Outer Write-Through non-transient |
| 11RW | Normal Memory, Outer Write-Back non-transient |

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

| Attr<n>[3:0] | Meaning when Attr<n>[7:4] is 0000 | Meaning when Attr<n>[7:4] is not 0000 |
|-----------------|-----------------------------------|--|
| 0000 | Device-nGnRnE memory | UNPREDICTABLE |
| 00RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through transient |
| 0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
| 01RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back transient |
| 1000 | Device-nGRE memory | Normal Memory, Inner Write-Through non-transient (RW=00) |
| 10RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through non-transient |
| 1100 | Device-GRE memory | Normal Memory, Inner Write-Back non-transient (RW=00) |
| 11RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
|--------|-------------|
| 0 | No Allocate |
| 1 | Allocate |

Accessing the HMAIR0:

To access the HMAIR0:

MRC p15,4,<Rt>,c10,c2,0 ; Read HMAIR0 into Rt
MCR p15,4,<Rt>,c10,c2,0 ; Write Rt to HMAIR0

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1010 | 0010 | 000 |

G6.2.63 HMAIR1, Hyp Memory Attribute Indirection Register 1

The HMAIR1 characteristics are:

Purpose

Along with [HMAIR0](#), provides the memory attribute encodings corresponding to the possible AttrIndx values in a Long-descriptor format translation table entry for stage 1 translations for memory accesses from Hyp mode.

AttrIndx[2] indicates the HMAIR register to be used:

- When AttrIndx[2] is 0, [HMAIR0](#) is used.
- When AttrIndx[2] is 1, HMAIR1 is used.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

AttrIndx[2], from the translation table descriptor, selects the appropriate HMAIR: setting AttrIndx[2] to 1 selects HMAIR1.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T10==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T10==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HMAIR1 is architecturally mapped to AArch64 System register [MAIR_EL2\[63:32\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HMAIR1 is a 32-bit register.

Field descriptions

The HMAIR1 bit assignments are:

When $TTBCR.EAE=1$:

Attr<n>, bits $[8(n-4)+7:8(n-4)]$, for n = 4 to 7

The memory attribute encoding for an AttrIdx[2:0] entry in a Long descriptor format translation table entry, where:

- AttrIdx[2:0] gives the value of <n> in Attr<n>.
- AttrIdx[2] defines which MAIR to access. Attr7 to Attr4 are in MAIR1, and Attr3 to Attr0 are in MAIR0.

Bits [7:4] are encoded as follows:

| Attr<n>[7:4] | Meaning |
|-----------------|--|
| 0000 | Device memory. See encoding of Attr<n>[3:0] for the type of Device memory. |
| 00RW, RW not 00 | Normal Memory, Outer Write-Through transient |
| 0100 | Normal Memory, Outer Non-cacheable |
| 01RW, RW not 00 | Normal Memory, Outer Write-Back transient |
| 10RW | Normal Memory, Outer Write-Through non-transient |
| 11RW | Normal Memory, Outer Write-Back non-transient |

R = Outer Read-Allocate policy, W = Outer Write-Allocate policy.

The meaning of bits [3:0] depends on the value of bits [7:4]:

| Attr<n>[3:0] | Meaning when Attr<n>[7:4] is 0000 | Meaning when Attr<n>[7:4] is not 0000 |
|-----------------|-----------------------------------|--|
| 0000 | Device-nGnRnE memory | UNPREDICTABLE |
| 00RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through transient |
| 0100 | Device-nGnRE memory | Normal memory, Inner Non-cacheable |
| 01RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back transient |
| 1000 | Device-nGRE memory | Normal Memory, Inner Write-Through non-transient (RW=00) |
| 10RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Through non-transient |
| 1100 | Device-GRE memory | Normal Memory, Inner Write-Back non-transient (RW=00) |
| 11RW, RW not 00 | UNPREDICTABLE | Normal Memory, Inner Write-Back non-transient |

R = Inner Read-Allocate policy, W = Inner Write-Allocate policy.

The R and W bits in some Attr<n> fields have the following meanings:

| R or W | Meaning |
|--------|-------------|
| 0 | No Allocate |
| 1 | Allocate |

Accessing the HMAIR1:

To access the HMAIR1:

MRC p15,4,<Rt>,c10,c2,1 ; Read HMAIR1 into Rt
MCR p15,4,<Rt>,c10,c2,1 ; Write Rt to HMAIR1

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1010 | 0010 | 001 |

G6.2.64 HPFAR, Hyp IPA Fault Address Register

The HPFAR characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T6==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T6==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HPFAR is architecturally mapped to AArch64 System register [HPFAR_EL2\[31:0\]](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HPFAR is a 32-bit register.

Field descriptions

The HPFAR bit assignments are:

Execution in any Non-secure mode other than Hyp mode makes this register UNKNOWN.

FIPA[39:12], bits [31:4]

Bits [39:12] of the faulting intermediate physical address.

Bits [3:0]

Reserved, RES0.

Accessing the HPFAR:

To access the HPFAR:

MRC p15,4,<Rt>,c6,c0,4 ; Read HPFAR into Rt
MCR p15,4,<Rt>,c6,c0,4 ; Write Rt to HPFAR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0110 | 0000 | 100 |

G6.2.65 HRMR, Hyp Reset Management Register

The HRMR characteristics are:

Purpose

When this register is implemented:

- A write to the register can request a Warm reset.
- If EL2 can use AArch32 and AArch64, this register specifies the Execution state that the PE boots into on a Warm reset.

Usage constraints

This register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

However, see [Configurations](#) for information about whether the register is implemented.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state.

Subject to the prioritization rules:

If `HSTR.T12==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.

If `HSTR_EL2.T12==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HRMR is architecturally mapped to AArch64 System register [RMR_EL2](#).

Only implemented if EL2 is the highest implemented Exception level. In this case:

- If EL2 can use AArch32 and AArch64 then this register must be implemented.
- If EL2 cannot use AArch64 then it is IMPLEMENTATION DEFINED whether the register is implemented.

When this register is not implemented its encoding is UNDEFINED.

See the field descriptions for the reset values. These apply whenever the register is implemented.

Attributes

HRMR is a 32-bit register.

Field descriptions

The HRMR bit assignments are:

Bits [31:2]

Reserved, RES0.

RR, bit [1]

Reset Request. Setting this bit to 1 requests a Warm reset.

This field resets to 0 on a Warm or Cold reset.

AA64, bit [0]

When EL2 can use AArch64, determines which Execution state the PE boots into after a Warm reset:

0 AArch32.

1 AArch64.

On coming out of the Warm reset, execution starts at the IMPLEMENTATION DEFINED reset vector address of the specified Execution state.

If EL2 cannot use AArch64 this bit is RAZ/WI.

When implemented as an RW field, this field resets to 0 on a Cold reset. It is not affected by a Warm reset.

Accessing the HRMR:

To access the HRMR when EL2 implemented, EL3 not implemented:

MRC p15,4,<Rt>,c12,c0,2 ; Read HRMR into Rt

MCR p15,4,<Rt>,c12,c0,2 ; Write Rt to HRMR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1100 | 0000 | 010 |

G6.2.66 HSCTLR, Hyp System Control Register

The HSCTLR characteristics are:

Purpose

Provides top level control of the system operation in Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HSCTLR is architecturally mapped to AArch64 System register [SCTLR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

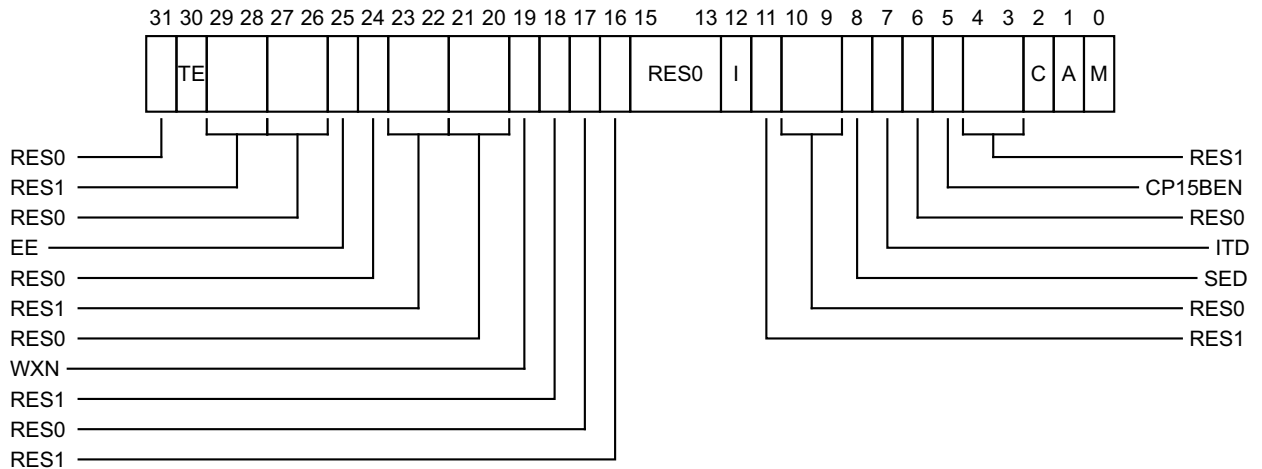

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSCTLR is a 32-bit register.

Field descriptions

The HSCTLR bit assignments are:

Bit [31]

Reserved, RES0.

TE, bit [30]

T32 Exception Enable. This bit controls whether exceptions to EL2 are taken to A32 or T32 state:

0 Exceptions, including reset, taken to A32 state.

1 Exceptions, including reset, taken to T32 state.

This field resets to a value that is architecturally UNKNOWN.

Bits [29:28]

Reserved, RES1.

Bits [27:26]

Reserved, RES0.

EE, bit [25]

The value of the PSTATE.E bit on entry to Hyp mode, the endianness of stage 1 translation table walks in the EL2 translation regime, and the endianness of stage 2 translation table walks in the PL1&0 translation regime.

The possible values of this bit are:

0 Little-endian. PSTATE.E is cleared to 0 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are little-endian.

1 Big-endian. PSTATE.E is set to 1 on entry to Hyp mode. Stage 1 translation table walks in the EL2 translation regime, and stage 2 translation table walks in the PL1&0 translation regime are big-endian.

If an implementation does not provide Big-endian support at Exception Levels higher than EL0, this bit is RES0.

If an implementation does not provide Little-endian support at Exception Levels higher than EL0, this bit is RES1.

When this register has an architecturally-defined reset value, if this field is implemented as an RW field, it resets to an IMPLEMENTATION DEFINED value.

Bit [24]

Reserved, RES0.

Bits [23:22]

Reserved, RES1.

Bits [21:20]

Reserved, RES0.

WXN, bit [19]

Write permission implies XN (Execute-never). For the EL2 translation regime, this bit can force all memory regions that are writable to be treated as XN. The possible values of this bit are:

- 0 This control has no effect on memory access permissions.
- 1 Any region that is writable in the EL2 translation regime is forced to XN for accesses from software executing at EL2.

The WXN bit is permitted to be cached in a TLB.

This field resets to a value that is architecturally UNKNOWN.

Bit [18]

Reserved, RES1.

Bit [17]

Reserved, RES0.

Bit [16]

Reserved, RES1.

Bits [15:13]

Reserved, RES0.

I, bit [12]

Instruction access Cacheability control, for accesses at EL2:

- 0 All instruction access to Normal memory from EL2 are Non-cacheable for all levels of instruction and unified cache.
If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Non-cacheable, Outer Non-cacheable memory.
- 1 All instruction access to Normal memory from EL2 can be cached at all levels of instruction and unified cache.
If the value of HSCTLR.M is 0, instruction accesses from stage 1 of the EL2 translation regime are to Normal, Outer Shareable, Inner Write-Through, Outer Write-Through memory.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

Bit [11]

Reserved, RES1.

Bits [10:9]

Reserved, RES0.

SED, bit [8]

SETEND instruction disable. Disables SETEND instructions at EL2.

- 0 SETEND instruction execution is enabled at EL2.
- 1 SETEND instructions are UNDEFINED at EL2.

If the implementation does not support mixed-endian operation at EL2, this bit is RES1.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

ITD, bit [7]

IT Disable. Disables some uses of IT instructions at EL2.

- | | | | | | | | | | | | | | |
|------------------|---|----------------|---|------------------|--|------------------|------------------|------------------|--------------------|------------------|---|------------------|---|
| 0 | All IT instruction functionality is enabled at EL2. | | | | | | | | | | | | |
| 1 | Any attempt at EL2 to execute any of the following is UNDEFINED: <ul style="list-style-type: none"> • All encodings of the IT instruction with hw1[3:0]!=1000. • All encodings of the subsequent instruction with the following values for hw1: <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">11xxxxxxxxxxxx</td> <td>All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM.</td> </tr> <tr> <td style="padding-right: 10px;">1011xxxxxxxxxxxx</td> <td>All instructions in <i>Miscellaneous 16-bit instructions on page F3-2442</i>.</td> </tr> <tr> <td style="padding-right: 10px;">10100xxxxxxxxxxx</td> <td>ADD Rd, PC, #imm</td> </tr> <tr> <td style="padding-right: 10px;">01001xxxxxxxxxxx</td> <td>LDR Rd, [PC, #imm]</td> </tr> <tr> <td style="padding-right: 10px;">0100x1xxx1111xxx</td> <td>ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC.</td> </tr> <tr> <td style="padding-right: 10px;">010001xx1xxxx111</td> <td>ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn.</td> </tr> </table> | 11xxxxxxxxxxxx | All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM. | 1011xxxxxxxxxxxx | All instructions in <i>Miscellaneous 16-bit instructions on page F3-2442</i> . | 10100xxxxxxxxxxx | ADD Rd, PC, #imm | 01001xxxxxxxxxxx | LDR Rd, [PC, #imm] | 0100x1xxx1111xxx | ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC. | 010001xx1xxxx111 | ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn. |
| 11xxxxxxxxxxxx | All 32-bit instructions, and the 16-bit instructions B, UDF, SVC, LDM, and STM. | | | | | | | | | | | | |
| 1011xxxxxxxxxxxx | All instructions in <i>Miscellaneous 16-bit instructions on page F3-2442</i> . | | | | | | | | | | | | |
| 10100xxxxxxxxxxx | ADD Rd, PC, #imm | | | | | | | | | | | | |
| 01001xxxxxxxxxxx | LDR Rd, [PC, #imm] | | | | | | | | | | | | |
| 0100x1xxx1111xxx | ADD Rdn, PC; CMP Rn, PC; MOV Rd, PC; BX PC; BLX PC. | | | | | | | | | | | | |
| 010001xx1xxxx111 | ADD PC, Rm; CMP PC, Rm; MOV PC, Rm. This pattern also covers UNPREDICTABLE cases with BLX Rn. | | | | | | | | | | | | |

These instructions are always UNDEFINED, regardless of whether they would pass or fail the condition code check that applies to them as a result of being in an IT block.

It is IMPLEMENTATION DEFINED whether the IT instruction is treated as:

- A 16-bit instruction, that can only be followed by another 16-bit instruction.
- The first half of a 32-bit instruction.

This means that, for the situations that are UNDEFINED, either the second 16-bit instruction or the 32-bit instruction is UNDEFINED.

An implementation might vary dynamically as to whether IT is treated as a 16-bit instruction or the first half of a 32-bit instruction.

If an instruction in an active IT block that would be disabled by this field sets this field to 1 then behavior is CONSTRAINED UNPREDICTABLE. For more information see [Changes to an ITD control by an instruction in an IT block on page E1-2298](#).

ITD is optional, but if it is implemented in the SCTLRL then it must also be implemented in the HSCTLRL. If it is not implemented then this bit is RAZ/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bit [6]

Reserved, RES0.

CP15BEN, bit [5]

System instruction memory barrier enable. Enables accesses to the DMB, DSB, and ISB System instructions in the (coproc==1111) encoding space from EL2:

- | | |
|---|---|
| 0 | EL2 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is UNDEFINED. |
| 1 | EL2 execution of the CP15DMB , CP15DSB , and CP15ISB instructions is enabled. |

CP15BEN is optional, but if it is implemented in the SCTLRL then it must also be implemented in the HSCTLRL. If it is not implemented then this bit is RAO/WI.

If this field is implemented as an RW field, it resets to a value that is architecturally UNKNOWN.

Bits [4:3]

Reserved, RES1.

C, bit [2]

Cacheability control, for data accesses at EL2:

- 0 All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, are Non-cacheable for all levels of data and unified cache.
- 1 All data access to Normal memory from EL2, and all accesses to the EL2 translation tables, can be cached at all levels of data and unified cache.

This bit has no effect on the PL1&0 translation regime.

When this register has an architecturally-defined reset value, this field resets to 0.

A, bit [1]

Alignment check enable. This is the enable bit for Alignment fault checking at EL2:

- 0 Alignment fault checking disabled when executing at EL2.
 Instructions that load or store one or more registers, other than load/store exclusive and load-acquire/store-release, do not check that the address being accessed is aligned to the size of the data element or data elements being accessed.
- 1 Alignment fault checking enabled when executing at EL2.
 All instructions that load or store one or more registers have an alignment check that the address being accessed is aligned to the size of the data element or data elements being accessed. If this check fails it causes an Alignment fault, which is taken as a Data Abort exception.

Load/store exclusive and load-acquire/store-release instructions have an alignment check regardless of the value of the A bit.

This field resets to a value that is architecturally UNKNOWN.

M, bit [0]

MMU enable for EL2 stage 1 address translation. Possible values of this bit are:

- 0 EL2 stage 1 address translation disabled.
 See the HSCTLR.I field for the behavior of instruction accesses to Normal memory.
- 1 EL2 stage 1 address translation enabled.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSCTLR:

To access the HSCTLR:

```
MRC p15,4,<Rt>,c1,c0,0 ; Read HSCTLR into Rt
MCR p15,4,<Rt>,c1,c0,0 ; Write Rt to HSCTLR
```

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0001 | 0000 | 000 |

G6.2.67 HSR, Hyp Syndrome Register

The HSR characteristics are:

Purpose

Holds syndrome information for an exception taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Execution in any Non-secure PE mode other than Hyp mode makes this register UNKNOWN.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of HSR is UNKNOWN. The value written to HSR must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T5==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T5==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HSR is architecturally mapped to AArch64 System register `ESR_EL2`.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSR is a 32-bit register.

Field descriptions

The HSR bit assignments are:

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about. Possible values of this field are:

EC == 000000

Unknown reason.

See [ISS encoding for exceptions with an unknown reason](#).

EC == 000001

Trapped WFI or WFE instruction execution.

Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

See [ISS encoding for an exception from a WFI or WFE instruction](#).

EC == 000011

Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000100

Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 000101

Trapped MCR or MRC access with (coproc==1110).

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 000110

Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

See [ISS encoding for an exception from an LDC or STC instruction](#).

EC == 000111

Access to Advanced SIMD or floating-point functionality trapped by a [HCPTR](#). {TASE, TCP10} control.

Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.

See [ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR](#).

EC == 001000

Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

See [ISS encoding for an exception from an MCR or MRC access](#).

EC == 001100

Trapped MRRC access with (coproc==1110).

See [ISS encoding for an exception from an MCRR or MRRC access](#).

EC == 001110

Illegal exception return to AArch32 state.

See [ISS encoding for an exception from an Illegal state or PC alignment fault](#).

EC == 010001

Exception on SVC instruction execution in AArch32 state routed to EL2.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010010

HVC instruction execution in AArch32 state, when HVC is not disabled.

See [ISS encoding for an exception from HVC or SVC instruction execution](#).

EC == 010011

Trapped execution of SMC instruction in AArch32 state.

See [ISS encoding for an exception from SMC instruction execution](#).

EC == 100000

Prefetch Abort from a lower Exception level.

See [ISS encoding for an exception from a Prefetch Abort](#).

EC == 100001

Prefetch Abort taken without a change in Exception level.

See [ISS encoding for an exception from a Prefetch Abort](#).

EC == 100010

PC alignment fault exception.

See [ISS encoding for an exception from an Illegal state or PC alignment fault](#).

EC == 100100

Data Abort from a lower Exception level.

See [ISS encoding for an exception from a Data Abort](#).

EC == 100101

Data Abort taken without a change in Exception level.

See [ISS encoding for an exception from a Data Abort](#).

All other EC values are reserved by ARM, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is **CONSTRAINED UNPREDICTABLE**, as described in [Reserved values in System and memory-mapped registers and translation table entries](#) on page K1-5492.

IL, bit [25]

Instruction length bit. Indicates the size of the instruction that has been trapped to Hyp mode. When this bit is valid, possible values of this bit are:

- 0 16-bit instruction trapped.
- 1 32-bit instruction trapped.

This field is RES1 and not valid for the following cases:

- When the EC field is 0b000000, indicating an exception with an unknown reason.
- Prefetch Aborts.
- Data Aborts that do not have valid ISS information, or for which the ISS is not valid.
- When the EC value is 0b001110, indicating an Illegal state exception.

———— **Note** —————

This is a change from the behavior in ARMv7, where the IL field is UNK/SBZP for the corresponding cases.

The IL field is not valid and is UNKNOWN on an exception from a PC alignment fault.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

The following subsections describe each ISS format.

ISS encoding for exceptions with an unknown reason

This encoding is used by:

- Unknown reason.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

This EC code is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction in the current PE mode in the current Security state, including:
 - A read access using a System register encoding pattern that is not allocated for reads at the current Exception level and Security state.
 - A write access using a System register encoding pattern that is not allocated for writes at the current Exception level and Security state.
 - Instruction encodings for instructions not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is unallocated in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is unallocated in Non-debug state.
- The attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the [SCTLR](#).{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
 - An HVC instruction when disabled by [HCR.HCD](#), [SCR.HCE](#), or [SCR_EL3.HCE](#).
 - An SMC instruction when disabled by [SCR.SCD](#) or [SCR_EL3.SMD](#).
 - An HLT instruction when disabled by [EDSCR.HDE](#).
- An exception generated because of the attempted execution of an MSR (Banked register) or MRS (Banked register) instruction that would access a Banked register that is not accessible from the Security state and PE mode at which the instruction was executed.

Note

An exception is generated only if the CONSTRAINED UNPREDICTABLE behavior of the instruction is that it is UNDEFINED, see [MSR/MRS Banked registers on page K1-5477](#).

- Attempted execution, in Debug state, of:
 - A DCPS1 instruction in Non-secure state from EL0 when EL2 is using AArch32 and the value of [HCR.TGE](#) is 1.

- A DCPS2 instruction at EL1 or EL0 when EL2 is not implemented, or when EL3 is using AArch32 and the value of `SCR.NS` is 0, or when EL3 is using AArch64 and the value of `SCR_EL3.NS` is 0.
- A DCPS3 instruction when EL3 is not implemented, or when the value of `EDSCR.SDD` is 1.
- In Debug state when the value of `EDSCR.SDD` is 1, the attempted execution at EL2, EL1, or EL0 of an instruction that is configured to trap to EL3.

Undefined Instruction exception, when the value of `HCR.TGE` is 1 on page G1-3829 describes the configuration settings for a trap that returns an `HSR.EC` value of `0b000000`.

ISS encoding for an exception from a WFI or WFE instruction

This encoding is used by:

- Trapped WFI or WFE instruction execution.
Conditional WFE and WFI instructions that fail their condition code check do not cause an exception.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to `0b1110`.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to `0b1110`, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the `SPSR.IT` field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

Bits [19:1]

Reserved, RES0.

TI, bit [0]

Trapped instruction. Possible values of this bit are:

- 0 WFI trapped.
- 1 WFE trapped.

Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3904 describes the configuration settings for this trap.

ISS encoding for an exception from an MCR or MRC access

This encoding is used by:

- Trapped MCR or MRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MCR or MRC access with (coproc==1110).
- Trapped VMRS access, from ID group trap, that is not reported using EC 0b000111.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value 0b000.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value 0b111.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value 0b0000.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- | | |
|---|---|
| 0 | Write to System register space. MCR instruction. |
| 1 | Read from System register space. MRC or VMRS instruction. |

The following sections describe configuration settings for traps that are reported using EC value 0b000011:

- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to the ID registers on page G1-3901.](#)
- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to lockdown, DMA, and TCM operations on page G1-3900.](#)
- [Traps to Hyp mode of Non-secure EL1 execution of cache maintenance instructions on page G1-3899.](#)
- [Traps to Hyp mode of Non-secure EL1 execution of TLB maintenance instructions on page G1-3898.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to the Auxiliary Control Register on page G1-3899.](#)
- [Traps to Hyp mode of Non-secure EL0 and EL1 accesses to Performance Monitors registers on page G1-3912.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to the CPACR on page G1-3906.](#)
- [Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-3897.](#)
- [General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the \(coproc == 0b1111\) encoding space on page G1-3908.](#)

The following sections describe configuration settings for traps that are reported using EC value 0b000101:

- [ID group 0, Primary device identification registers on page G1-3902.](#)
- [Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-3907.](#)

- [Trapping Non-secure System register accesses to Debug ROM registers on page G1-3910.](#)
- [Trapping Non-secure System register accesses to powerdown debug registers on page G1-3910.](#)
- [Trapping general Non-secure System register accesses to debug registers on page G1-3911.](#)

The following sections describes configuration settings for traps that are reported using EC value 0b001000:

- [ID group 0, Primary device identification registers on page G1-3902.](#)
- [ID group 3, Detailed feature identification registers on page G1-3904.](#)

ISS encoding for an exception from an MCRR or MRRC access

This encoding is used by:

- Trapped MCRR or MRRC access with (coproc==1111) that is not reported using EC 0b000000.
- Trapped MRRC access with (coproc==1110).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

Bits [15:14]

Reserved, RES0.

Rt2, bits [13:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

Bit [9]

Reserved, RES0.

Rt, bits [8:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

CRm, bits [4:1]

The CRm value from the issued instruction.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to System register space. MCRR instruction.
- 1 Read from System register space. MRRC instruction.

The following sections describe configuration settings for traps that are reported using EC value 0b000100:

- [Traps to Hyp mode of Non-secure EL1 accesses to virtual memory control registers on page G1-3897.](#)
- [General trapping to Hyp mode of Non-secure EL0 and EL1 accesses to System registers in the \(coproc == 0b1111\) encoding space on page G1-3908.](#)

The following sections describe configuration settings for traps that are reported using EC value 0b001100:

- [Traps to Hyp mode of Non-secure System register accesses to trace registers on page G1-3907.](#)
- [Trapping Non-secure System register accesses to Debug ROM registers on page G1-3910.](#)

ISS encoding for an exception from an LDC or STC instruction

This encoding is used by:

- Trapped LDC or STC access.

The only architected uses of these instructions are:

- An STC to write data to memory from [DBGDTRRXint](#).
- An LDC to read data from memory to [DBGDTRTXint](#).

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.

1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

imm8, bits [19:12]

The immediate value from the issued instruction.

Bits [11:9]

Reserved, RES0.

Rn, bits [8:5]

The Rn value from the issued instruction. Valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction.

When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

- 0 Subtract offset.
- 1 Add offset.

This bit corresponds to the U bit in the instruction encoding.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

- 000 Immediate unindexed.
- 001 Immediate post-indexed.
- 010 Immediate offset.
- 011 Immediate pre-indexed.
- 100 Literal unindexed.

LDC instruction in A32 instruction set only.

For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.

110 Literal offset.
 LDC instruction only.
 For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5477.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

Direction, bit [0]

Indicates the direction of the trapped instruction. The possible values of this bit are:

- 0 Write to memory. STC instruction.
- 1 Read from memory. LDC instruction.

Trapping general Non-secure System register accesses to debug registers on page G1-3911 describes the configuration settings for the trap that is reported using EC value 0b000110.

ISS encoding for an exception from an access to SIMD or floating-point functionality, resulting from HCPTR

This encoding is used by:

- Access to Advanced SIMD or floating-point functionality trapped by a HCPTR.{TASE, TCP10} control. Excludes exceptions generated because Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.

The ISS encoding for these exceptions is:

Excludes exceptions that occur because Advanced SIMD and floating-point functionality is not implemented, or because the value of HCR.TGE or HCR_EL2.TGE is 1. These are reported with EC value 0b000000.

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.

- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

Bits [19:6]

Reserved, RES0.

TA, bit [5]

Indicates trapped use of Advanced SIMD functionality. The possible values of this bit are:

- 0 Exception was not caused by trapped use of Advanced SIMD functionality.
- 1 Exception was caused by trapped use of Advanced SIMD functionality.

Any use of an Advanced SIMD instruction that is not also a floating-point instruction that is trapped to Hyp mode because of a trap configured in the HCPTR sets this bit to 1.

For a list of these instructions, see *Controls of Advanced SIMD operation that do not apply to floating-point operation* on page E1-2306.

Bit [4]

Reserved, RES0.

coproc, bits [3:0]

When the TA field returns the value 1, this field returns the value 1010, otherwise this field is RES0.

The following sections describe the configuration settings for the traps that are reported using EC value 0b000111:

- [General trapping to Hyp mode of Non-secure accesses to the SIMD and floating-point registers](#) on page G1-3905.
- [Traps to Hyp mode of Non-secure accesses to Advanced SIMD functionality](#) on page G1-3906.

ISS encoding for an exception from HVC or SVC instruction execution

This encoding is used by:

- Exception on SVC instruction execution in AArch32 state routed to EL2.
- HVC instruction execution in AArch32 state, when HVC is not disabled.

The ISS encoding for these exceptions is:

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, this is the value of the imm16 field of the issued instruction.

For an SVC instruction:

- If the instruction is unconditional, then:
 - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
 - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-3829 describes the configuration settings for the trap reported with EC value 0b010001.

ISS encoding for an exception from SMC instruction execution

This encoding is used by:

- Trapped execution of SMC instruction in AArch32 state.

The ISS encoding for these exceptions is:

CV, bit [24]

Condition code valid. Possible values of this bit are:

- 0 The COND field is not valid.
- 1 The COND field is valid.

When an A32 instruction is trapped, CV is set to 1.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

COND, bits [23:20]

The condition code for the trapped instruction.

When an A32 instruction is trapped, CV is set to 1 and:

- If the instruction is conditional, COND is set to the condition code field value from the instruction.
- If the instruction is unconditional, COND is set to 0b1110.

A conditional A32 instruction that is known to pass its condition code check can be presented either:

- With COND set to 0b1110, the value for unconditional.
- With the COND value held in the instruction.

When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:

- CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.

- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

For an implementation that, for both A32 and T32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is only valid if CCKNOWNPASS is 1, otherwise it is RES0.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

- 0 The instruction was unconditional, or was conditional and passed its condition code check.
- 1 The instruction was conditional, and might have failed its condition code check.

Bits [18:0]

Reserved, RES0.

Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3901 describes the configuration settings for this trap, for instructions executed in Non-secure PL1 modes.

ISS encoding for an exception from a Prefetch Abort

This encoding is used by:

- Prefetch Abort from a lower Exception level.
- Prefetch Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

Bits [24:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 HIFAR is valid.
- 1 HIFAR is not valid, and holds an UNKNOWN value.

This field is only valid if the IFSC code is 010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code. Possible values of this field are:

| | |
|--------|---|
| 000000 | Address size fault, translation table base register |
| 000001 | Address size fault, level 1 |
| 000010 | Address size fault, level 2 |
| 000011 | Address size fault, level 3 |
| 000101 | Translation fault, level 1 |
| 000110 | Translation fault, level 2 |
| 000111 | Translation fault, level 3 |
| 001001 | Access flag fault, level 1 |
| 001010 | Access flag fault, level 2 |
| 001011 | Access flag fault, level 3 |
| 001101 | Permission fault, level 1 |
| 001110 | Permission fault, level 2 |
| 001111 | Permission fault, level 3 |
| 010000 | Synchronous external abort, not on translation table walk |
| 011000 | Synchronous parity or ECC error on memory access, not on translation table walk |
| 010101 | Synchronous external abort, on translation table walk, level 1 |
| 010110 | Synchronous external abort, on translation table walk, level 2 |
| 010111 | Synchronous external abort, on translation table walk, level 3 |
| 011101 | Synchronous parity or ECC error on memory access on translation table walk, level 1 |
| 011110 | Synchronous parity or ECC error on memory access on translation table walk, level 2 |
| 011111 | Synchronous parity or ECC error on memory access on translation table walk, level 3 |
| 100010 | Debug exception, only when the EC value is 0b100001 |
| 110000 | TLB conflict abort |

All other values are reserved. The effect of programming this field to a reserved value is that behavior is CONstrained UNPREDICTABLE, as described in [Reserved values in System and memory-mapped registers and translation table entries on page K1-5477](#).

For more information about the lookup level associated with a fault, see [The level associated with MMU faults on a Long-descriptor translation table lookup on page G4-4131](#).

The following sections describe cases where Prefetch Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100000:

- [Abort exceptions, when the value of HCR.TGE is 1 on page G1-3830](#).
- [Routing debug exceptions to EL2 on page G1-3833](#).

ISS encoding for an exception from an Illegal state or PC alignment fault

This encoding is used by:

- Illegal exception return to AArch32 state.
- PC alignment fault exception.

The ISS encoding for these exceptions is:

Bits [24:0]

Reserved, RES0.

For more information about the Illegal state exception, see:

- [Illegal changes to PSTATE.M on page G1-3809.](#)
- [Illegal return events from AArch32 state on page G1-3835.](#)
- [Legal returns that set PSTATE.IL to 1 on page G1-3837.](#)
- [The Illegal Execution state exception on page G1-3837.](#)

For more information about the PC alignment fault exception, see [Branching to an unaligned PC on page K1-5458.](#)

ISS encoding for an exception from a Data Abort

This encoding is used by:

- Data Abort from a lower Exception level.
- Data Abort taken without a change in Exception level.

The ISS encoding for these exceptions is:

ISV, bit [24]

Instruction syndrome valid. Indicates whether the syndrome information in ISS[23:14] is valid.

- 0 No valid instruction syndrome. ISS[23:14] are RES0.
- 1 ISS[23:14] hold a valid instruction syndrome.

This bit is 0 for all faults except Data Aborts generated by stage 2 address translations for which all the following apply to the instruction that generated the Data Abort exception:

- The instruction is an LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT instruction.
- The instruction is not performing register writeback.
- The instruction is not using the PC as a source or destination register.

For these cases, ISV is UNKNOWN if the exception was generated in Debug state in memory access mode, as described in *Data Aborts in Memory access mode* on page H4-4914, and otherwise indicates whether ISS[23:14] hold a valid syndrome.

———— **Note** ————

In the A32 instruction set, LDR*T and STR*T instructions always perform register writeback and therefore never return a valid instruction syndrome.

ISV is set to 0 on a stage 2 abort on a stage 1 translation table lookup.

It is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a Synchronous external abort on stage 2 translation table walk.

SAS, bits [23:22]

Syndrome Access Size. When ISV is 1, indicates the size of the access attempted by the faulting operation.

| | |
|----|------------|
| 00 | Byte |
| 01 | Halfword |
| 10 | Word |
| 11 | Doubleword |

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

SSE, bit [21]

Syndrome Sign Extend. When ISV is 1, for a byte, halfword, or word load operation, indicates whether the data item must be sign extended. For these cases, the possible values of this bit are:

| | |
|---|----------------------------------|
| 0 | Sign-extension not required. |
| 1 | Data item must be sign-extended. |

For all other operations this bit is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bit [20]

Reserved, RES0.

SRT, bits [19:16]

Syndrome Register transfer. When ISV is 1, the register number of the Rt operand of the faulting instruction.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bit [15]

Reserved, RES0.

AR, bit [14]

Acquire/Release. When ISV is 1, the possible values of this bit are:

- 0 Instruction did not have acquire/release semantics.
- 1 Instruction did have acquire/release semantics.

This field is UNKNOWN when the value of ISV is UNKNOWN.

This field is RES0 when the value of ISV is 0.

Bits [13:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a Synchronous external abort other than a Synchronous external abort on a translation table walk.

- 0 [HDFAR](#) is valid.
- 1 [HDFAR](#) is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of external aborts.

For any abort other than an External abort this bit returns a value of 0.

CM, bit [8]

Cache maintenance. For a synchronous fault, identifies fault that comes from a cache maintenance or address translation instruction. For synchronous faults, the possible values of this bit are:

- 0 Fault not generated by a cache maintenance or address translation instruction.
- 1 Fault generated by a cache maintenance or address translation instruction.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

- 0 Fault not on a stage 2 translation for a stage 1 translation table walk.
- 1 Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by a write instruction or a read instruction. The possible values of this bit are:

- 0 Abort caused by a read instruction.
- 1 Abort caused by a write instruction.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For an asynchronous Data Abort exception this bit is UNKNOWN.

DFSC, bits [5:0]

Data Fault Status Code. Possible values of this field are:

- 000000 Address size fault, translation table base register
- 000001 Address size fault, level 1
- 000010 Address size fault, level 2
- 000011 Address size fault, level 3

| | |
|--------|---|
| 000101 | Translation fault, level 1 |
| 000110 | Translation fault, level 2 |
| 000111 | Translation fault, level 3 |
| 001001 | Access flag fault, level 1 |
| 001010 | Access flag fault, level 2 |
| 001011 | Access flag fault, level 3 |
| 001101 | Permission fault, level 1 |
| 001110 | Permission fault, level 2 |
| 001111 | Permission fault, level 3 |
| 010000 | Synchronous external abort, not on translation table walk |
| 011000 | Synchronous parity or ECC error on memory access, not on translation table walk |
| 010001 | SError interrupt |
| 011001 | SError interrupt from a parity or ECC error on memory access |
| 010101 | Synchronous external abort, on translation table walk, level 1 |
| 010110 | Synchronous external abort, on translation table walk, level 2 |
| 010111 | Synchronous external abort, on translation table walk, level 3 |
| 011101 | Synchronous parity or ECC error on memory access on translation table walk, level 1 |
| 011110 | Synchronous parity or ECC error on memory access on translation table walk, level 2 |
| 011111 | Synchronous parity or ECC error on memory access on translation table walk, level 3 |
| 100001 | Alignment fault |
| 100010 | Debug exception, only when the EC value is 0b100100 |
| 110000 | TLB conflict abort |
| 110100 | IMPLEMENTATION DEFINED fault (Lockdown fault) |
| 110101 | IMPLEMENTATION DEFINED fault (Unsupported Exclusive access fault) |

All other values are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5477.

For more information about the lookup level associated with a fault, see *The level associated with MMU faults on a Long-descriptor translation table lookup* on page G4-4131.

The following describe cases where Data Abort exceptions can be routed to Hyp mode, generating exceptions that are reported in the HSR with EC value 0b100100:

- *Abort exceptions, when the value of HCR.TGE is 1* on page G1-3830.
- *Routing debug exceptions to EL2* on page G1-3833.

The following describe cases that can cause a Data Abort exception that is taken to Hyp mode, and reported in the HSR with EC value of 0b100000 or 0b100100:

- *Hyp mode control of Non-secure access permissions* on page G4-4075.
- *Memory fault reporting in Hyp mode* on page G4-4135.

Accessing the HSR:

To access the HSR:

```
MRC p15,4,<Rt>,c5,c2,0 ; Read HSR into Rt
MCR p15,4,<Rt>,c5,c2,0 ; Write Rt to HSR
```

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0101 | 0010 | 000 |

G6.2.68 HSTR, Hyp System Trap Register

The HSTR characteristics are:

Purpose

Controls trapping to Hyp mode of Non-secure accesses, at EL1 or lower, to the System register in the coproc == 1111 encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T1==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T1==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HSTR is architecturally mapped to AArch64 System register `HSTR_EL2`.

If EL2 is not implemented, this register is RES0 from EL3.

Some or all RW fields of this register have defined reset values. These apply only if the PE resets into EL2 with EL2 using AArch32, or into EL3 with EL3 using AArch32. Otherwise, RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HSTR is a 32-bit register.

Field descriptions

The HSTR bit assignments are:

Bits [31:16]

Reserved, RES0.

T<n>, bit [n], for n = 0 to 15

Fields T14 and T4 are RES0.

The remaining fields control whether Non-secure EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == 1111 encoding space are trapped to Hyp mode:

- 0 This control has no effect on Non-secure EL0 or EL1 accesses to System registers.
- 1 Any Non-secure EL1 MCR, MRC access with coproc == 1111 and CRn == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.
 Any Non-secure EL1 MCRR, MRRC access with coproc == 1111 and CRm == <n> is trapped to Hyp mode if the access is not UNDEFINED when the value of this field is 0.

For example, when HSTR.T7 is 1:

- Any 32-bit access from a Non-secure EL1 mode, using an MCR or MRC instruction with coproc set to 1111 and <CRn> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.
- Any 64-bit access from a Non-secure EL1 mode, using an MCRR or MRRC instruction with coproc set to 1111 and <CRm> set to c7, and that is not UNDEFINED when HSTR.T7 is 0, is trapped to Hyp mode.

When this register has an architecturally-defined reset value, this field resets to 0.

Accessing the HSTR:

To access the HSTR:

```
MRC p15,4,<Rt>,c1,c1,3 ; Read HSTR into Rt
MCR p15,4,<Rt>,c1,c1,3 ; Write Rt to HSTR
```

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 0001 | 0001 | 011 |

G6.2.69 HTCR, Hyp Translation Control Register

The HTCR characteristics are:

Purpose

Controls translation table walks required for the stage 1 translation of memory accesses from Hyp mode, and holds cacheability and shareability information for the accesses.

Used in conjunction with [HTTBR](#), that defines the translation table base address for the translations.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state](#) on page G1-3816 for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64](#) on page D1-1548 for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T2==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T2==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HTCR is architecturally mapped to AArch64 System register [TCR_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTCR is a 32-bit register.

Field descriptions

The HTCR bit assignments are:

Bit [31]

Reserved, RES1.

IMP DEF, bit [30]

IMPLEMENTATION DEFINED.

Bits [29:24]

Reserved, RES0.

Bit [23]

Reserved, RES1.

Bits [22:14]

Reserved, RES0.

SH0, bits [13:12]

Shareability attribute for memory associated with translation table walks using [HTTBR](#).

| | |
|----|-----------------|
| 00 | Non-shareable |
| 10 | Outer Shareable |
| 11 | Inner Shareable |

Other values are reserved. The effect of programming this field to a Reserved value is that behavior is CONstrained UNPREDICTABLE, as described in *Reserved values in System and memory-mapped registers and translation table entries* on page K1-5477.

ORGN0, bits [11:10]

Outer cacheability attribute for memory associated with translation table walks using [HTTBR](#).

| | |
|----|--|
| 00 | Normal memory, Outer Non-cacheable |
| 01 | Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable |

IRGN0, bits [9:8]

Inner cacheability attribute for memory associated with translation table walks using [HTTBR](#).

| | |
|----|--|
| 00 | Normal memory, Inner Non-cacheable |
| 01 | Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable |
| 10 | Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable |
| 11 | Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable |

Bits [7:3]

Reserved, RES0.

T0SZ, bits [2:0]

The size offset of the memory region addressed by [HTTBR](#). The region size is $2^{(32-T0SZ)}$ bytes.

Accessing the HTCR:

To access the HTCR:

```
MRC p15,4,<Rt>,c2,c0,2 ; Read HTCR into Rt  
MCR p15,4,<Rt>,c2,c0,2 ; Write Rt to HTCR
```

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 100 | 0010 | 0000 | 010 |

G6.2.70 HTPIDR, Hyp Software Thread ID Register

The HTPIDR characteristics are:

Purpose

Provides a location where software running in Hyp mode can store thread identifying information that is not visible to Non-secure software executing at EL0 or EL1, for hypervisor management purposes.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T13==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T13==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HTPIDR is architecturally mapped to AArch64 System register `TPIDR_EL2[31:0]`.

If EL2 is not implemented, this register is `RES0` from EL3.

The PE never updates this register. This means the register is always UNKNOWN on reset.

Attributes

HTPIDR is a 32-bit register.

Field descriptions

The HTPIDR bit assignments are:

Bits [31:0]

Thread ID. Thread identifying information stored by software running at this Exception level.

Accessing the HTPIDR:

To access the HTPIDR:

MRC p15,4,<Rt>,c13,c0,2 ; Read HTPIDR into Rt
MCR p15,4,<Rt>,c13,c0,2 ; Write Rt to HTPIDR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1101 | 0000 | 010 |

G6.2.71 HTTBR, Hyp Translation Table Base Register

The HTTBR characteristics are:

Purpose

Holds the base address of the translation table for the stage 1 translation of memory accesses from Hyp mode.

Used in conjunction with the [HTCR](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T2==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T2==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HTTBR is architecturally mapped to AArch64 System register [TTBR0_EL2](#).

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HTTBR is a 64-bit register.

Field descriptions

The HTTBR bit assignments are:

Bits [63:48]

Reserved, RES0.

BADDR, bits [47:0]

Translation table base address, bits[47:x], Bits [x-1:0] are RES0, with the additional requirement that if bits[x-1:3] are not all zero, this is a misaligned translation table base address, with effects that are CONSTRAINED UNPREDICTABLE, and must be one of the following:

- Register bits [x-1:3] are treated as if all the bits are zero. The value read back from these bits is either the value written or zero.
- The result of the calculation of an address for a translation table walk using this register can be corrupted in those bits that are nonzero.

x is determined from the value of [HTCR.TOSZ](#) as follows:

- If [HTCR.TOSZ](#) is 0 or 1, $x = 5 - \text{HTCR.TOSZ}$.
- If [HTCR.TOSZ](#) is greater than 1, $x = 14 - \text{HTCR.TOSZ}$.

If bits[47:40] of the translation table base address are not zero, an Address size fault is generated.

Accessing the HTTBR:

To access the HTTBR:

MRRC p15,4,<Rt>,<Rt2>,c2 ; Read HTTBR[31:0] into Rt and HTTBR[63:32] into Rt2
MCRR p15,4,<Rt>,<Rt2>,c2 ; Write Rt to HTTBR[31:0] and Rt2 to HTTBR[63:32]

Register access is encoded as follows:

| coproc | opc1 | CRm |
|--------|------|------|
| 1111 | 0100 | 0010 |

G6.2.72 HVBAR, Hyp Vector Base Address Register

The HVBAR characteristics are:

Purpose

Holds the vector base address for any exception that is taken to Hyp mode.

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | - | RW | RW | - |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | - | RW |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HSTR.T12==1`, Non-secure accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T12==1`, Non-secure accesses to this register from EL1 are trapped to EL2.

Configurations

AArch32 System register HVBAR is architecturally mapped to AArch64 System register `VBAR_EL2[31:0]`.

If EL2 is not implemented, this register is RES0 from EL3.

RW fields in this register reset to architecturally UNKNOWN values.

Attributes

HVBAR is a 32-bit register.

Field descriptions

The HVBAR bit assignments are:

Bits [31:5]

Vector Base Address. Bits[31:5] of the base address of the exception vectors for exceptions taken to this Exception level. Bits[4:0] of an exception vector are the exception offset.

Bits [4:0]

Reserved, RES0.

Accessing the HVBAR:

To access the HVBAR:

MRC p15,4,<Rt>,c12,c0,0 ; Read HVBAR into Rt
MCR p15,4,<Rt>,c12,c0,0 ; Write Rt to HVBAR

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 100 | 1100 | 0000 | 000 |

G6.2.73 ICIALLU, Instruction Cache Invalidate All to PoU

The ICIALLU characteristics are:

Purpose

Invalidate all instruction caches to PoU. If branch predictors are architecturally visible, also flush branch predictors.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction ICIALLU performs the same function as AArch64 System instruction [IC IALLU](#).

Attributes

ICIALLU is a 32-bit System instruction.

Field descriptions

ICIALLU ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ICIALLU instruction:

The ICIALLU instruction is executed as:

MCR p15,0,<Rt>,c7,c5,0 ; ICIALLU operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 0101 | 000 |

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

G6.2.74 ICIALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The ICIALLUIS characteristics are:

Purpose

Invalidate all instruction caches Inner Shareable to PoU. If branch predictors are architecturally visible, also flush branch predictors.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction ICIALLUIS performs the same function as AArch64 System instruction [IC IALLUIS](#).

Attributes

ICIALLUIS is a 32-bit System instruction.

Field descriptions

ICIALLUIS ignores the value in the register specified by the instruction. Software does not have to write a value to the register before issuing this instruction.

Executing the ICIALLUIS instruction:

The ICIALLUIS instruction is executed as:

MCR p15,0,<Rt>,c7,c1,0 ; ICIALLUIS operation, ignoring the value in Rt

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 0001 | 000 |

The PE ignores the value of <Rt>. Software does not have to write a value to this register before issuing this instruction.

G6.2.75 ICIMVAU, Instruction Cache line Invalidate by VA to PoU

The ICIMVAU characteristics are:

Purpose

Invalidate instruction cache line by virtual address to PoU.

Usage constraints

If EL3 is implemented and is using AArch32, this instruction can be executed at the following exception levels:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | WO | WO | WO | WO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | WO | WO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HCR_EL2.TPU==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.
- If `HSTR.T7==1`, Non-secure execution of this instruction at EL1 is trapped to Hyp mode.
- If `HSTR_EL2.T7==1`, Non-secure execution of this instruction at EL1 is trapped to EL2.

Configurations

AArch32 System instruction ICIMVAU performs the same function as AArch64 System instruction [IC IVAU](#).

Attributes

ICIMVAU is a 32-bit System instruction.

Field descriptions

The ICIMVAU input value bit assignments are:

Bits [31:0]

Virtual address to use.

Executing the ICIMVAU instruction:

The ICIMVAU instruction is executed as:

MCR p15,0,<Rt>,c7,c5,1 ; ICIMVAU operation

The instruction is encoded in the System instruction encoding space as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|---------------|-------------|------------|------------|-------------|
| 1111 | 000 | 0111 | 0101 | 001 |

G6.2.76 ID_AFR0, Auxiliary Feature Register 0

The ID_AFR0 characteristics are:

Purpose

Provides information about the IMPLEMENTATION DEFINED features of the PE in AArch32.

Must be interpreted with the Main ID Register, [MIDR](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4169](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If [HCR.TID3==1](#), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HCR_EL2.TID3==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.
- If [HSTR.T0==1](#), Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If [HSTR_EL2.T0==1](#), Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_AFR0 is architecturally mapped to AArch64 System register [ID_AFR0_EL1](#).

Attributes

ID_AFR0 is a 32-bit register.

Field descriptions

The ID_AFR0 bit assignments are:

Bits [31:16]

Reserved, RES0.

IMPLEMENTATION DEFINED, bits [15:12]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [11:8]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [7:4]

IMPLEMENTATION DEFINED.

IMPLEMENTATION DEFINED, bits [3:0]

IMPLEMENTATION DEFINED.

Accessing the ID_AFR0:

To access the ID_AFR0:

MRC p15,0,<Rt>,c0,c1,3 ; Read ID_AFR0 into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0000 | 0001 | 011 |

G6.2.77 ID_DFR0, Debug Feature Register 0

The ID_DFR0 characteristics are:

Purpose

Provides top level information about the debug system in AArch32.

Must be interpreted with the Main ID Register, [MIDR](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4169](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables

For a description of the prioritization of any generated exceptions, see [Synchronous exception prioritization for exceptions taken to AArch32 state on page G1-3816](#) for exceptions taken to AArch32 state, and [Synchronous exception prioritization for exceptions taken to AArch64 on page D1-1548](#) for exceptions taken to AArch64 state. Subject to the prioritization rules:

- If `HCR.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HCR_EL2.TID3==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.
- If `HSTR.T0==1`, Non-secure read accesses to this register from EL1 are trapped to Hyp mode.
- If `HSTR_EL2.T0==1`, Non-secure read accesses to this register from EL1 are trapped to EL2.

Configurations

There is one instance of this register that is used in both Secure and Non-secure states.

AArch32 System register ID_DFR0 is architecturally mapped to AArch64 System register [ID_DFR0_EL1](#).

Attributes

ID_DFR0 is a 32-bit register.

Field descriptions

The ID_DFR0 bit assignments are:

| | | | | | | | | | | | | | | | |
|------|---------|----------|---------|--------|---------|---------|--------|----|----|----|---|---|---|---|---|
| 31 | 28 | 27 | 24 | 23 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 4 | 3 | 0 |
| RES0 | PerfMon | MProfDbg | MMapTrc | CopTrc | MMapDbg | CopSDBG | CopDbg | | | | | | | | |

Bits [31:28]

Reserved, RES0.

PerfMon, bits [27:24]

Performance Monitors. Support for System registers-based ARM Performance Monitors Extension, using registers in the coproc == 1111 encoding space, for A and R profile processors. Defined values are:

| | |
|------|--|
| 0000 | Performance Monitors Extension System registers not implemented. |
| 0001 | Support for Performance Monitors Extension version 1 (PMUv1) System registers. |
| 0010 | Support for Performance Monitors Extension version 2 (PMUv2) System registers. |
| 0011 | Support for Performance Monitors Extension version 3 (PMUv3) System registers. |
| 1111 | IMPLEMENTATION DEFINED form of Performance Monitors System registers supported. PMUv3 not supported. |

All other values are reserved.

In ARMv8-A the permitted values are 0000, 0011, and 1111.

In ARMv7, the value 0000 can mean that PMUv1 is implemented. PMUv1 is not permitted in an ARMv8 implementation.

MProfDbg, bits [23:20]

M Profile Debug. Support for memory-mapped debug model for M profile processors. Defined values are:

| | |
|------|--|
| 0000 | Not supported. |
| 0001 | Support for M profile Debug architecture, with memory-mapped access. |

All other values are reserved.

In ARMv8-A the only permitted value is 0000.

MMapTrc, bits [19:16]

Memory Mapped Trace. Support for memory-mapped trace model. Defined values are:

| | |
|------|--|
| 0000 | Not supported. |
| 0001 | Support for ARM trace architecture, with memory-mapped access. |

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In the Trace registers, the ETMIDR gives more information about the implementation.

CopTrc, bits [15:12]

Support for System registers-based trace model, using registers in the coproc == 1110 encoding space. Defined values are:

| | |
|------|---|
| 0000 | Not supported. |
| 0001 | Support for ARM trace architecture, with System registers access. |

All other values are reserved.

In ARMv8-A the permitted values are 0000 and 0001.

In the Trace registers, the ETMIDR gives more information about the implementation.

MMapDbg, bits [11:8]

Memory Mapped Debug. Support for v7 memory-mapped debug model, for A and R profile processors.

In ARMv8-A this field is RES0.

The optional memory map defined by ARMv8 is not compatible with ARMv7.

CopSDBG, bits [7:4]

Support for a System registers-based Secure debug model, using registers in the coproc = 1110 encoding space, for an A profile processor that includes EL3.

If EL3 is not implemented and the implemented Security state is Non-Secure state, this field is RES0. Otherwise, this field reads the same as bits [3:0].

CopDBG, bits [3:0]

Support for System registers-based debug model, using registers in the coproc == 1110 encoding space, for A and R profile processors. Defined values are:

- 0000 Not supported.
- 0010 Support for ARMv6, v6 Debug architecture, with System registers access.
- 0011 Support for ARMv6, v6.1 Debug architecture, with System registers access.
- 0100 Support for ARMv7, v7 Debug architecture, with System registers access.
- 0101 Support for ARMv7, v7.1 Debug architecture, with System registers access.
- 0110 Support for ARMv8 debug architecture, with System registers access.

All other values are reserved.

In ARMv8-A the permitted values are 0000, and 0110.

Accessing the ID_DFR0:

To access the ID_DFR0:

MRC p15,0,<Rt>,c0,c1,2 ; Read ID_DFR0 into Rt

Register access is encoded as follows:

| coproc | opc1 | CRn | CRm | opc2 |
|--------|------|------|------|------|
| 1111 | 000 | 0000 | 0001 | 010 |

G6.2.78 ID_ISAR0, Instruction Set Attribute Register 0

The ID_ISAR0 characteristics are:

Purpose

Provides information about the instruction sets implemented by the PE in AArch32.

Must be interpreted with [ID_ISAR1](#), [ID_ISAR2](#), [ID_ISAR3](#), [ID_ISAR4](#), and [ID_ISAR5](#).

For general information about the interpretation of the ID registers see [Principles of the ID scheme for fields in ID registers on page G4-4169](#).

Usage constraints

If EL3 is implemented and is using AArch32, this register is accessible as follows:

| EL0 (NS) | EL0 (S) | EL1 (NS) | EL2 (NS) | EL3 (SCR.NS=1) | EL3 (SCR.NS=0) |
|----------|---------|----------|----------|----------------|----------------|
| - | - | RO | RO | RO | RO |

If EL3 is not implemented or EL3 is implemented and is using AArch64, this register is accessible as follows:

| EL0 | EL1 | EL2 (NS) |
|-----|-----|----------|
| - | RO | RO |

Traps and Enables
