- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

E2.5 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness.*
- *Data endianness on page E2-2326.*

E2.5.1 General description of endianness in the ARM architecture

This section only describes memory addressing and the effects of endianness for data elements up to doubleword of 64 bits. However, this description can be extended to apply to larger data elements.

For an address A, [Figure E2-2](#) shows, for big-endian and little-endian memory systems, the relationship between:

- The doubleword at address A.
- The words at addresses A and A+4.
- The halfwords at addresses A, A+2, A+4, and A+6.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.

The terms in [Figure E2-2](#) have the following definitions:

MSByte Most-significant byte.

LSByte Least-significant byte.

In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure E2-2 Endianness relationships in AArch32 state

E2.5.2 Instruction endianness

In ARMv8-A, the mapping of instruction memory is always little-endian.

E2.5.3 Data endianness

The size of the data value that is loaded or stored is the size that is used for the purpose of endian conversion for floating-point, Advanced SIMD, and general-purpose register loads and stores.

Table E2-2 shows the element sizes of all the load/store instructions, for all instruction sets.

Table E2-2 Element size of load/store instructions

| Instructions | Element size |
|--|--|
| LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, TBB | Byte |
| LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH | Halfword |
| LDR, LDRT, LDREX, STR, STRT, STREX | Word |
| LDRD, LDREXD, STRD, STREXD | Word |
| All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM, | Word |
| LDC, STC | Word |
| Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit Si registers | Word |
| Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit Di registers | Doubleword |
| VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4 | Element size of the Advanced SIMD access |

CPSR.E determines the data endianness.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for Advanced SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for Advanced SIMD element and data structure loads and stores. For more information see *Endianness in Advanced SIMD* on page E2-2327.

Instructions to reverse bytes in registers

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table E2-3 shows the instructions that provide this functionality in the A32 and T32 instruction sets.

Table E2-3 Byte reversal instructions

| Function | T32 / A32 Instruction | Notes |
|---|-----------------------|---|
| Reverse bytes in whole register | REV | For use with general purpose registers. |
| Reverse bytes in 16-bit halfwords | REV16 | For use with general purpose registers. |
| Reverse bytes in halfword and sign-extend | REVSH | For use with general purpose registers. |
| Reverse elements in doublewords, vector | VREV64 | For use with registers in the SIMD and floating-point register file |
| Reverse elements in words, vector | VREV32 | For use with registers in the SIMD and floating-point register file |
| Reverse elements in halfwords, vector | VREV16 | For use with registers in the SIMD and floating-point register file |

Endianness in Advanced SIMD

Advanced SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the PE to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the A32 or T32 instruction:

```
VLD1.16 {D0}, [R1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure E2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

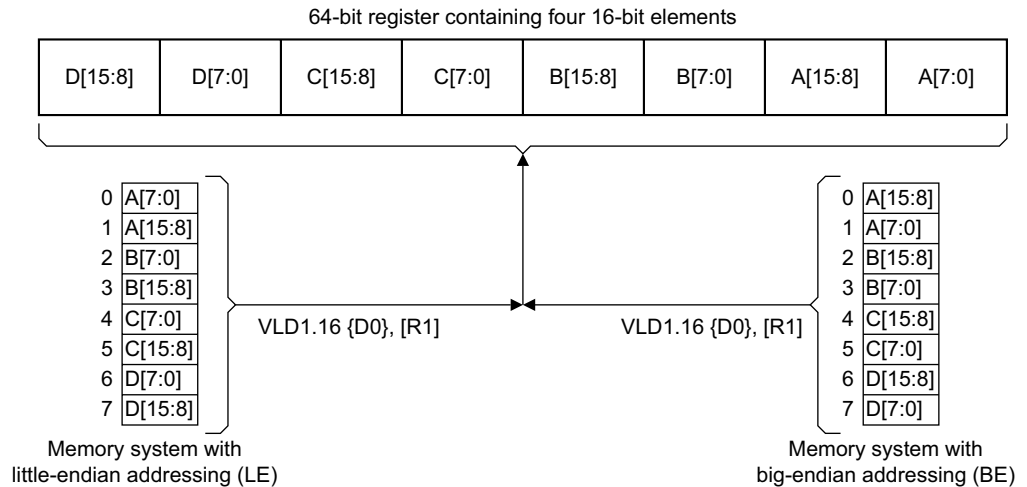

Figure E2-3 Advanced SIMD byte order example for AArch32 state

For information about the alignment of Advanced SIMD instructions see [Alignment support on page E2-2323](#).

The `BigEndian()` pseudocode function determines the current endianness of the data.

The `BigEndianReverse()` pseudocode function reverses the endianness of a bitstring.

The `BigEndian()` and `BigEndianReverse()` functions are defined in [Chapter J1 ARMv8 Pseudocode](#).

E2.6 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The ARM architecture description refers to two types of atomicity, *single-copy atomicity* and *multi-copy atomicity*. In the ARMv8 architecture, the atomicity requirements for memory accesses depend on the memory type, and whether the access is explicit or implicit. For more information see:

- [Requirements for single-copy atomicity.](#)
- [Properties of single-copy atomic accesses on page E2-2329.](#)
- [Multi-copy atomicity on page E2-2329.](#)
- [Requirements for multi-copy atomicity on page E2-2330.](#)
- [Concurrent modification and execution of instructions on page E2-2330.](#)

For more information about the memory types, see [Memory type overview on page E2-2317.](#)

E2.6.1 Requirements for single-copy atomicity

In AArch32 state, the single-copy atomic PE accesses are:

- All byte accesses.
- All halfword accesses to halfword-aligned locations.
- All word accesses to word-aligned locations.
- Memory accesses caused by LDREXD and STREXD instructions to doubleword-aligned locations.

LDM, LDC, LDRD, STM, STC, STRD, PUSH, POP, RFE, SRS, VLDM, VLDR, VSTM, and VSTR instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

LDRD and STRD accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

————— **Note** —————

This requirement has been added to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- The element size is 64 bits, or smaller.
- The elements are naturally aligned.

Accesses to 64-bit elements or structures that are 32-bit aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic. The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When an access is not single-copy atomic by the rules described in this section, it is executed as a sequence of one or more accesses that aggregate to the size of the original access. Each of the accesses in this sequence is single-copy atomic, at least at the byte level.

———— **Note** —————

In this section, the terms *before the write operation* and *after the write operation* mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, a synchronous Data Abort exception or Debug state entry can be taken during that sequence. This causes execution of the instruction to be abandoned. See [Data Abort exception on page G1-3859](#).

If the synchronous Data Abort exception is returned from using the preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that was performed before the exception was taken is repeated. This also applies to an exit from Debug state.

———— **Note** —————

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:

- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
 - At 32-bit granularity in A32 state.
 - At 16-bit granularity in T32 state.
- [Concurrent modification and execution of instructions on page E2-2330](#) describes additional constraints on the behavior of instruction fetches.
- Translation table walks are performed using accesses that are single-copy atomic:
 - At 32-bit granularity when using Short-descriptor format translation tables.
 - At 64-bit granularity when using Long-descriptor format translation tables.

E2.6.2 Properties of single-copy atomic accesses

A read or write operation that is *single-copy atomic* has the following properties:

1. For a single-copy atomic store, if the store overlaps another single-copy atomic store, then all of the writes from one of the stores are inserted into the *Coherence order* of each overlapping byte before any of the writes of the other store are inserted into the *Coherence orders* of the overlapping bytes.
2. If a single-copy atomic load overlaps a single-copy atomic store and for any of the overlapping bytes the load returns the data written by the write inserted into the *Coherence order* of that byte by the single-copy atomic store then the load must return data from a point in the *Coherence order* no earlier than the writes inserted into the *Coherence order* by the single-copy atomic store of all of the overlapping bytes.

E2.6.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

———— **Note** —————

Writes that are not coherent are not multi-copy atomic.

E2.6.4 Requirements for multi-copy atomicity

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory with the non-Gathering attribute, writes that are single-copy atomic are also multi-copy atomic.

For Device memory with the Gathering attribute, writes are not required to be multi-copy atomic.

E2.6.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification is a:

- B, BL, NOP, BKPT, SVC, HVC, or SMC A32 instruction
- B, BL, BLX, NOP, BKPT, or SVC 16-bit T32 instruction.

In addition, for the T32 instructions, for which *Instruction encodings* on page F2-2402 describes the meaning of {hw1, hw2}:

- hw1 of a 32-bit BL (immediate) instruction can be concurrently modified to hw1 of another BL (immediate) instruction:
 - This means that some of the most significant bits of the immediate value can be modified.
- hw1 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw1 of another BLX immediate instruction:
 - This means that some of the most significant bits of the immediate value can be modified.
- hw1 of a 32-bit BL (immediate) or BLX (immediate) instruction can be concurrently modified to a T32 16-bit B, BL, BLX, BKPT, or SVC instruction. This modification also works in reverse.
- hw2 of a 32-bit BL (immediate) instruction can be concurrently modified to hw2 of another BL (immediate) instruction with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit BLX (immediate) instruction can be concurrently modified to hw2 of another BLX (immediate) instruction with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit B (immediate) instruction with a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction with a condition field with a different immediate:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.
- hw2 of a 32-bit B (immediate) instruction without a condition field can be concurrently modified to hw2 of another 32-bit B (immediate) instruction without a condition field:
 - This means that some bits of the immediate value, including the least significant bits, can be modified.

————— Note —————

In the T32 instruction set:

- The only encodings of BKPT and SVC are 16-bit.
- The only encoding of BL is 32-bit.

For the instructions explicitly identified in this section, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

The instructions to which this applies are the B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the *always* condition.

For all other instructions, to avoid UNPREDICTABLE or CONSTRAINED UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.
2. To ensure that the modified instructions are observable, the PE that modified the instructions must issue the following sequence of instructions and operations:

```

; Coherency example for self-modifying code
; Enter this code with <Rt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Rn. Use STRH in the first
; line instead of STR for a 16-bit instruction.
STR <Rt>, [Rn]
DCCMVAU Rn          ; Clean data cache by MVA to point of unification (PoU)
DSB                 ; Ensure visibility of the data stored
ICIMVAU Rn          ; Invalidate instruction cache by VA to PoU
BPIMVA Rn           ; Invalidate branch predictor by MVA to PoU
DSB                 ; Ensure completion of the invalidations
    
```

———— **Note** ————

The DCCMVAU operation is not required if the area of memory is either Non-cacheable or Write-through Cacheable.

3. In a multiprocessor system, the ICIMVAU and BPIMVA are broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```

ISB                 ; Synchronize fetched instruction stream
    
```

For more information about the required synchronization operation, see [Synchronization and coherency issues between data and instruction accesses](#) on page E2-2320.

———— **Note** ————

For information about memory accesses caused by instruction fetches, see [Ordering requirements](#) on page E2-2333.

E2.7 Memory ordering

This section describes observation ordering. It contains the following subsections:

- [Observability and completion.](#)
- [Ordering requirements on page E2-2333.](#)
- [Memory barriers on page E2-2335.](#)
- [Summary of the memory ordering rules on page E2-2339.](#)

For information on endpoint ordering of memory accesses, see [Reordering on page E2-2349.](#)

In the ARMv8 memory model, the shareability memory attribute indicates whether hardware must ensure memory coherency.

The ARMv8 memory system architecture defines additional attributes and associated behaviors, defined in the system level section of this manual. See:

- [Chapter G3 The AArch32 System Level Memory Model.](#)
- [Chapter G4 The AArch32 Virtual Memory System Architecture.](#)

See also [Mismatched memory attributes on page E2-2352.](#)

E2.7.1 Observability and completion

An *observer* is a master in the system that is capable of observing memory accesses. For a PE, the following mechanisms must be treated as independent observers:

- The mechanism that performs reads or writes to memory.
- A mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These are treated as reads.
- A mechanism that performs translation table walks. These are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, *subsequent* means whichever of the following is appropriate to the context:

- After the point in time where the location is observed by that observer.
- After the point in time where the location is globally observed.

For all memory:

- A write to a location in memory is said to be *observed* by an observer when:
 - A subsequent read of the location by the same observer returns the value written by the observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the observed write.
 - A subsequent write of the location by the same observer is sequenced in the *Coherence order* of the location after the observed write.
- A write to a location in memory is said to be *globally observed* for a shareability domain or set of observers when:
 - A subsequent read of the location by any observer in that shareability domain returns the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the globally observed write.
 - A subsequent write of the location by any observer in that shareability domain is sequenced in the *Coherence order* of the location after the globally observed write.
- A read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer has no effect on the value returned by the read.
- A read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain has no effect on the value returned by the read.

Additionally, for Device-nGnRnE memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
 - Meets the general conditions listed.
 - Can begin to affect the state of the memory-mapped peripheral.
 - Can trigger all associated side-effects, whether they affect other peripheral devices, processors, or memory.

———— **Note** —————

This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
 - The read or write is globally observed for that shareability domain.
 - Any translation table walks associated with the read or write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.
- A cache or TLB maintenance instruction is complete for a shareability domain when the effects of the instruction are globally observed for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

The completion of any cache or TLB maintenance instruction includes its completion on all processors that are affected by both the instruction and the DSB operation that is required to guarantee visibility of the maintenance instruction.

Completion of side-effects of accesses to Device memory

The completion of a memory access to Device memory is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

E2.7.2 Ordering requirements

ARMv8 defines restrictions for the permitted ordering of memory accesses. These restrictions depend on the memory type of the addresses that are accessed, see [Memory types and attributes on page E2-2342](#).

———— **Note** —————

See [Summary of the memory ordering rules on page E2-2339](#) for the definition of *address dependency*.

For accesses to all memory types, the only stores by an observer that can be observed by another observer are those stores that have been *Architecturally executed*. Speculative writes by an observer cannot be observed by another observer. For the purposes of this requirement, speculative writes are all of:

- Writes generated by store instructions that appear in the *Execution stream* after a branch that is not architecturally resolved.
- Writes generated by store instructions that appear in the *Execution stream* after an instruction where a synchronous exception condition has not been architecturally resolved.
- Writes generated by conditional store instructions for which the conditions for the instruction have not been architecturally resolved.
- Writes generated by store instructions for which the data being written comes from a register that has not been architecturally committed.

The following additional restrictions apply to the order in which accesses to memory are observed:

- Reads and writes can be observed in any order provided the following constraints are met:
 - If an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the common shareability domain of the memory addresses being accessed.
 - Ordering can be achieved by using a DMB or DSB barrier. For more information on DMB and DSB instructions, see [Memory barriers on page E2-2335](#).
- Reads and writes to the same address are coherent within the shareability domain of the memory address being accessed.
- Two reads to the same address by the same observer are observed in program order by all observers within the shareability domain of the memory address being accessed.
- Writes are not required to be multi-copy atomic. This means that in the absence of barriers, the observation of a store by one observer does not imply the observation of the store by another observer.
- Instructions that access multiple elements have no defined ordering requirements for the memory accesses relative to each other.

For Device memory with the non-Reordering attribute, the order of memory accesses arriving at a *single peripheral* is the same as occurs in a [Simple sequential execution on page Glossary-5728](#) of the program. This means the accesses arrive in program order. This ordering applies for all accesses using any of the memory types with the non-Reordering attribute, which means Device-nGnRE accesses are ordered with respect to Device-nGnRE accesses to the same peripheral. If the memory accesses are not to a peripheral then there are no ordering restrictions from the non-Reordering attribute. For the purposes of this definition, a *single peripheral* is a region of memory of an IMPLEMENTATION DEFINED size that is defined by the peripheral.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by an ISB or other [Context synchronization event](#).

Address dependencies and order

In the ARMv8 architecture, a register data dependency between the value returned by a load instruction and the address used by a subsequent memory transaction creates order between that load instruction and the subsequent memory transaction.

A register data dependency exists between a first data value and a second data value when either:

- The register used to hold the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
 - A conditional branch whose condition is determined by the first data value.
 - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.
- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

———— Note —————

A register data dependency can exist even if the value of the first data value is discarded as part of the calculation, as might be the case if it is ANDed with 0x0 or if arithmetic using the first data value cancels out its contribution.

For example, each of the following code sequences creates order between the memory transactions:

Sequence 1 LDR R1, [R2]
 AND R1, R1, #0
 LDR R4, [R3, R1]

Sequence 2 LDR R1, [R2]
 ADD R3, R3, R1

SUB R3, R3, R1
STR R4, [R3]

E2.7.3 Memory barriers

The ARM architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

- [Instruction Synchronization Barrier \(ISB\)](#).
- [Data Memory Barrier \(DMB\)](#) on page E2-2336.
- [Data Synchronization Barrier \(DSB\)](#) on page E2-2337.
- [Shareability and access limitations on the data barrier operations](#) on page E2-2337.
- [Load-Acquire, Store-Release](#) on page E2-2338.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

AArch32 state also supports the legacy barrier instructions [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#). These instructions are executed as MCRs using the appropriate encoding, and are accessible from EL0. However, for performance reasons ARM deprecates any use of these operations, and strongly recommends that software uses the DMB, DSB, and ISB instructions described in this section instead. Optionally, an implementation can support a CP15DEN control that supervisory software can use to disable use of these instructions, meaning the corresponding MCR encodings are UNDEFINED. When the CP15BEN control is supported, setting one of the following CP15BEN fields to 0 makes execution of [CP15DMB](#), [CP15DSB](#), and [CP15ISB](#) UNDEFINED:

- [SCTLR_EL1](#).CP15BEN, for execution of these instructions at EL0 using AArch32 when EL1 is using AArch64.
- [SCTLR](#).CP15BEN, for execution of these instructions at EL0 or EL1 when EL1 is using AArch32.
- [HSCTLR](#).CP15BEN, for execution of these instructions at EL2 when EL2 is using AArch32.

Instruction Synchronization Barrier (ISB)

An ISB instruction flushes the pipeline in the PE, so that all instructions that come after the ISB instruction in program order are fetched from the cache or memory after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to System registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

The pseudocode function for the operation of an ISB is [InstructionSynchronizationBarrier\(\)](#).

See also [Memory barriers on page G3-4019](#).

Data Memory Barrier (DMB)

The DMB instruction is a data memory barrier. The PE that executes the DMB instruction is referred to as the executing PE, PE_e. The DMB instruction takes an <option> argument that specifies the shareability domains and access types to which the instruction applies, see [Shareability and access limitations on the data barrier operations on page E2-2337](#).

If the required shareability is *Full system* then the operation applies to all observers within the system.

A DMB creates two groups of memory accesses, Group A and Group B:

Group A Contains:

- All explicit memory accesses of the required access types from observers in the same required shareability domain as PE_e that are observed by PE_e before the DMB instruction. These accesses include any accesses of the required access types performed by PE_e.
- All loads of required access types from an observer PE_x in the same required shareability domain as PE_e that have been observed by any given different observer, PE_y, in the same required shareability domain as PE_e before PE_y has performed a memory access that is a member of Group A.

Group B Contains:

- All explicit memory accesses of the required access types by PE_e that occur in program order after the DMB instruction.
- All explicit memory accesses of the required access types by any given observer PE_x in the same required shareability domain as PE_e that can only occur after a load by PE_x has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as PE_e observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory addresses accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a DMB NSH is sufficient for this guarantee.

Note

- A memory access might be in neither Group A nor Group B. The DMB does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by PE_y of a load before PE_y performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by PE_e that is a member of Group B as a result of the first part of the definition of Group B.

DMB only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see [About cache maintenance in ARMv8 on page G3-3995](#). It has no effect on the ordering of any other instructions executing on the PE. A DMB intended to ensure the completion of cache maintenance instructions must have an access type of both loads and stores.

The pseudocode function for the operation of a DMB is [DataMemoryBarrier\(\)](#).

See also [Memory barrier instructions on page G3-4016](#) and [Memory barriers on page G3-4019](#).

Data Synchronization Barrier (DSB)

The DSB instruction is a memory barrier, that synchronizes the execution stream with memory accesses.

The DSB instruction takes an <option> argument that specifies the shareability domains and access types to which the instruction applies, see [Shareability and access limitations on the data barrier operations](#).

If the required shareability is *Full system* then the operation applies to all observers within the system.

A DSB behaves as a DMB with the same arguments, and also has the additional properties defined in this section. The PE that executes the DSB instruction is referred to as the executing PE, PEe.

Execution of a DSB at EL2 ensures that any memory accesses caused by speculative translation table walks from the Non-secure PL1&0 translation regime have been observed.

For more information, see [Use of out-of-context translation regimes on page G4-4028](#).

A DSB completes when all of the following apply:

- All explicit memory accesses that are observed by PEe before the DSB is executed and are of the required access types, and are from observers in the same required shareability domain as PEe, are complete for the set of observers in the required shareability domain.
- If the required access types of the DSB is reads and writes, then all cache and branch predictor maintenance instructions and all TLB maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can execute until the DSB completes.

See also [Memory barrier instructions on page G3-4016](#) and [Memory barriers on page G3-4019](#).

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
 - Full system.
 - Outer Shareable.
 - Inner Shareable.
 - Non-shareable.
- The accesses for which the instruction operates. This is one of:
 - Read and write accesses in Group A and Group B.
 - Write accesses only in Group A and Group B.
 - Read access only in Group A and read and write accesses in Group B.

Note

This form of a DMB or DSB instruction can be described as a Load-Load/Store barrier.

[Table E2-4](#) shows how these options are encoded in the <option> field of the instruction.

Table E2-4 Encoding of the DMB and DSB <option> parameter

| Accesses | | Shareability domain | | | |
|------------------|------------------|---------------------|-----------------|-----------------|---------------|
| Group A | Group B | Full system | Outer Shareable | Inner Shareable | Non-shareable |
| Reads and writes | Reads and writes | SY | OSH | ISH | NSH |
| Writes | Writes | ST | OSHST | ISHST | NSHST |
| Reads | Reads and writes | LD | OSHL | ISHL | NSHL |

If no <option> is specified then the instruction operates for read and write accesses, over the full system, meaning the operation is the same as for the SY option. See the instruction descriptions for more information:

- [DMB on page F5-2659](#).
- [DSB on page F5-2662](#).

Note

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation, see [ISB on page F5-2679](#).

Load-Acquire, Store-Release

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores.

For all memory types, these instructions have the following ordering requirements:

- A Store-Release followed by a Load-Acquire is observed in program order by each observer within the shareability domain of the memory address being accessed by the Store-Release and the memory address being accessed by the Load-Acquire.
- For a Load-Acquire, observers in the shareability domain of the address accessed by the Load-Acquire observe accesses in the following order:
 1. The read caused by the Load-Acquire.
 2. Reads and writes caused by loads and stores that appear in program order after the Load-Acquire for which the shareability of the address accessed by the load or store requires that the observer observes the access.

There are no other ordering requirements on loads or stores that appear before the Load-Acquire.

- For a Store-Release, observers in the shareability domain of the address accessed by the Store-Release observe accesses in the following order:
 1. All of the following for which the shareability of the address accessed requires that the observer observes the access:
 - Reads and writes caused by loads and stores that appear in program order before the Store-Release.
 - Writes that were observed by the PE executing the Store-Release before it executed the Store-Release.
 2. The write caused by the Store-Release.

There are no additional ordering requirements on loads or stores that appear in program order after the Store-Release.

- All Store-Release instructions must be multi-copy atomic when they are observed with Load-Acquire instructions.

In addition, for accesses to a memory-mapped peripheral of an arbitrary system-defined size that are defined as any type of Device memory accesses, these instructions have the following requirements:

- A Load-Acquire to an address in the memory-mapped peripheral ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.
- A Store-Release to an address in the memory-mapped peripheral ensures that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.

- If a Load-Acquire to a memory address in the memory-mapped peripheral has observed the value stored to that address by a Store-Release, then any memory access to the memory-mapped peripheral that is architecturally required to be ordered before the memory access of the Store-Release will arrive at the memory-mapped peripheral before any memory access to the same peripheral that is architecturally required to be ordered after the memory access of the Load-Acquire.

Load-Acquire and Store-Release, other than LDAEXD and STLEXD, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

LDAEXD and STLEXD access two data elements. The address supplied to the instructions must be doubleword aligned, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

———— **Note** —————

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
 - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
 - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

Table E2-5 summarizes the Load-Acquire/Store-release instructions.

Table E2-5 Load-Acquire/Store-Release instructions

| Data type | Load-Acquire | Store-Release | Load-Acquire Exclusive | Store-Release Exclusive |
|-------------------|--------------|---------------|------------------------|-------------------------|
| 32-bit word | LDA | STL | LDAEX | STLEX |
| 16-bit halfword | LDAH | STLH | LDAEXH | STLEXH |
| 8-bit byte | LDAB | STLB | LDAEXB | STLEXB |
| 64-bit doubleword | - | - | LDAEXD | STLEXD |

E2.7.4 Summary of the memory ordering rules

The following is a concise list of the situations that are required, by the ARM architecture specification, to cause externally-visible order of memory. This ordering means that if memory transaction A has externally visible order ahead of memory transaction B, then all observers within the shareability domains of A and B will observe A before B. See *Terms used in the summary of the memory ordering rules* on page E2-2340 for definitions of the terms used.

———— **Note** —————

This list applies to both AArch32 state and AArch64 state, and is consistent with the requirements of ARMv7.

1. DMB and DSB barrier instructions, and load acquire/store release instructions, create externally-visible order as defined by those instructions.
2. A True or False Address dependency from a Load to a Load or from a Load to a Store creates externally-visible order.
3. A True Control dependency from a Load to an ISB instruction creates externally-visible order between the load and any memory accesses after the ISB instruction.
4. A True Register data dependency from a Load to a Store creates externally-visible order.

5. A True Control dependency from a Load to a Store creates externally-visible order.
6. Memory is coherent within the shareability domain of a memory address, which means there is a total order of all writes to that address that all observers within that shareability domain will agree on.

———— **Note** ————

A consequence of this is that reads to the same address by the same processor are observed in order.

7. A Dependency from a Store to a Load through memory between different PEs creates externally-visible order but stores are not multi-copy atomic except where explicitly defined to be by the definition of the store.

———— **Note** ————

A consequence of the lack of multi-copy atomicity is that a Store to Load dependency through memory on the same PE does not create externally-visible order.

No other effects are required to create externally visible order in the ARM architecture.

Terms used in the summary of the memory ordering rules

The summary uses the following terms:

Register data dependency

This is defined in [Address dependencies and order on page E2-2334](#).

False Register data dependency

A False Register data dependency is a Register data dependency where no register in the system holds a variable for which a change of the first data value causes a change of the second data value.

True Register data dependency

A True Register data dependency is a Register data dependency that is not a false Register data dependency.

True Address dependency

A True Address dependency between a load and a subsequent memory transaction exists where there is a True Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

False Address dependency

A False Address dependency between a load and a subsequent memory transaction exists where there is a False Register data dependency between the data value returned from the load and the address used by the subsequent memory transaction.

True Control dependency

A True Control dependency between a load and a subsequent instruction exists:

- Where there is a True Register data dependency between the data value returned from the load and data value used in the evaluation of a conditional branch and the subsequent instruction is only executed as a result of one of the possible outcomes of that conditional branch.
- Where there is a True Register data dependency between the data value returned from the load and the data value used in the evaluation of a subsequent instruction that is a conditional selection, move or computation for which both:
 - The condition is determined by the returned data value.
 - No input data value for the selection, move or computation has a register data dependency on the returned data value.

Dependency from a Store to a Load through memory

A Dependency from a Store to a Load through memory exists where the Store and Load are to the same physical address, and value returned by the Load is the value that was written by the Store, and could not be the value that was previously held in that memory address.

E2.8 Memory types and attributes

In ARMv8 the ordering of accesses for addresses in memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- [Normal memory](#).
- [Device memory](#) on page E2-2346.
- [Memory access restrictions](#) on page E2-2351.

E2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware is permitted by the architecture to perform speculative data read accesses to these locations, regardless of the access permissions for these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that is Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See [Multi-register loads and stores that access Normal memory](#) on page E2-2346.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
 - Read accesses can be repeated with no side-effects.
 - Repeated read accesses return the last value written to the resource being read.
 - Read accesses can fetch additional memory locations with no side-effects.
 - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
 - Unaligned accesses can be supported.
 - Accesses can be merged before accessing the target memory system.
- An instruction that generates a sequence of accesses as described in [Atomicity in the ARM architecture](#) on page E2-2328 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- [Shareable Normal memory](#) on page E2-2343.
- [Non-shareable Normal memory](#) on page E2-2344.
- [Cacheability attributes for Normal memory](#) on page E2-2344.

See also:

- [Multi-register loads and stores that access Normal memory on page E2-2346.](#)
- [Atomicity in the ARM architecture on page E2-2328.](#)
- [Memory barriers on page E2-2335.](#) For accesses to Normal memory, a DMB instruction is required to ensure the required ordering.
- [Concurrent modification and execution of instructions on page E2-2330.](#)

Shareable Normal memory

A Normal memory location has a Shareability attribute that is defined as one of:

- Inner Shareable.
- Outer Shareable.
- Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see [Synchronization and coherency issues between data and instruction accesses on page E2-2320.](#)

Note

- System designers can use the Shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the Shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different PEs.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
 - The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.
-

The details of the use of the Shareability attributes are system-specific. [Example E2-1](#) shows how they might be used.

Example E2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
 - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
 - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different Shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same Shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable Shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable Shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Cacheability attributes for Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a Cacheability attribute that is one of:

- Write-Through Cacheable.
- Write-Back Cacheable.
- Non-cacheable.

Also, for Write-Through Cacheable and Write-Back Cacheable Normal memory regions:

- A region might be assigned cache allocation hints for read and write accesses.
- It is IMPLEMENTATION DEFINED whether the cache allocation hints can have an additional attribute of Transient or Non-transient.

For more information see [Cacheability, cache allocation hints, and cache transient hints on page G3-3992](#).

A memory location can be marked as having different cacheability attributes, for example when using aliases in a virtual to physical address mapping:

- If the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location.
- For other cases see [Mismatched memory attributes on page E2-2352](#).

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the Shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- A completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance.
- A completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

For Normal memory, the ARM architecture provides cacheability attributes that are defined independently for each of two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- Inner refers to the innermost caches, meaning the caches that are closest to the PE, and always includes the lowest level of cache.
- No cache that is controlled by the Inner cacheability attributes can lie outside a cache that is controlled by the Outer cacheability attributes.
- An implementation might not have any outer cache.

[Example E2-2](#), [Example E2-3 on page E2-2346](#), and [Example E2-4 on page E2-2346](#) describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the PE, see [Memory hierarchy on page E2-2318](#).
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the Shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example E2-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 and L2 cache.
 - The Outer cacheability attribute applied to L3 cache.
-

Example E2-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example E2-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- The Inner cacheability attribute applied to L1 cache.
 - The Outer cacheability attribute applied to L2 and L3 cache.
-

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more registers from the SIMD and floating-point register file from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

E2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

Gathering Identified as G or nG, see [Gathering on page E2-2348](#).

Reordering Identified as R or nR, see [Reordering on page E2-2349](#).

Early Write Acknowledgement hint

Identified as E or nE, see [Early Write Acknowledgement on page E2-2350](#).

The ARMv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early write acknowledgement.
Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.
Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.
ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory. The Device-nGRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

The Device-GRE memory type is introduced into the AArch32 translation table formats when the PE is using the Long Descriptor Translation Table format.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
- Earlier versions of the ARM architecture defined the following memory types:
 - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
 - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

An exception to this applies:

- Reads generated by the Advanced SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

Note

- An instruction that generates a sequence of accesses as described in [Atomicity in the ARM architecture on page E2-2328](#) might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.
 - Write speculation that is visible to other observers is prohibited for all memory types.

-
- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.
 - If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
 - A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.
 - Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
 - A memory location with any Device memory attribute cannot be allocated into a cache.
 - Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.

- All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

———— **Note** —————

In the Non-secure PL1&0 translation regime in systems where `HCR.TGE==1` and `HCR.DC==0`, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes the value of `HSR.ISS.[24]` to be 0.

- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

———— **Note** —————

This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

See also [Memory access restrictions on page E2-2351](#).

The memory types for Translation table walks cannot be defined as any Device memory type within the TCR. For the Non-secure EL1&0 translation regime, the memory accesses made during a stage 1 translation table walk are subject to a stage 2 translation, and as a result of this second stage of translation, the accesses from the first stage translation table walk might be made to memory locations with any Device memory type. These accesses might be made speculatively. When the value of the `HCR.PTW` bit is 1, a stage 2 permission fault is generated if a first stage translation table walk is made to any Device memory type.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

- G** Indicates that the location has the Gathering attribute.
- nG** Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See [Multi-register loads and stores that access Device memory on page E2-2350](#).

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
 - The accesses are not separated by a DMB or DSB barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
 - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
 - The accesses are not generated by a Store-Release instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the Non-gathering attribute.

An implementation is not permitted to perform an access with the Non-gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

- R** Indicates that the location has the Reordering attribute.
- nR** Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program. That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the DMB instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.

- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

Early Write Acknowledgement

In the Device memory attribute:

- E** Indicates that the location has the Early Write Acknowledgement attribute.
nE Indicates that the location has the No Early Write Acknowledgement attribute.

Early Write Acknowledgement is a hint to the platform memory system. Assigning the No Early Write Acknowledgement attribute to a Device memory location recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write acknowledge. This means that a DSB barrier, executed by the PE that performed the write to the No Early Write Acknowledgement location, completes only after the write has reached its endpoint in the memory system. Typically, this endpoint is a peripheral or physical memory.

When the Early Write Acknowledgement attribute is assigned to a Device memory location, there is no such recommendation for the handling of accesses to that location.

Note

- The Early Write Acknowledgement hint has no effect on the ordering rules. The purpose of signaling no Early Write Acknowledgement is to signal to the interconnect that the peripheral requires the ability to signal the acknowledgement. The No Write Acknowledgement signal also provides an additional semantic that can be interpreted by the driver that is accessing the peripheral.
- This attribute is treated as a hint, as the exact nature of the interconnects attached to a PE is outside the scope of the ARM architecture definition, and not all interconnects provide a mechanism to ensure that a write has reached the physical endpoint of the memory system.
- ARM recommends that writes with the No Early Write Acknowledgement hint are used for PCIe configuration writes. However, the mechanisms by which PCIe configuration writes are identified are IMPLEMENTATION DEFINED.
- ARM strongly recommends that the Early Write Acknowledgement hint is not ignored by a PE, but is made available for use by the system.

Because the No Early Write Acknowledgement attribute is a hint:

- An implementation is permitted to perform an access with the Early Write Acknowledgement attribute in a manner consistent with the requirements specified by the No Early Write Acknowledgement attribute.
- An implementation is permitted to perform an access with the No Early Write Acknowledgement attribute in a manner consistent with the relaxations allowed by the Early Write Acknowledgement attribute.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load and store instructions.

For all instructions that load or store one or more registers from the SIMD and floating-point register file there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load and store instructions.

For an LDRD, STRD, or LDM instruction with a register list that includes the PC, or an STM instruction with a register list that includes the PC, the order in which the registers are accessed is not defined by the architecture.

For a load or store of an Advanced SIMD element or structure, the order in which the registers are accessed is not defined by the architecture.

For a VLDM, VSTM, LDM and STM instruction with a register list that does not include the PC, all registers are accessed in ascending address order for Device accesses with the non-Reordering attribute.

E2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, p and q , that are generated by the same instruction:
 - The bytes p and q must have the same memory type and Shareability attributes. otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an LDC, LDM, LDRD STC, STM or STRD instruction, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
 - Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes p and q .

For the permitted CONSTRAINED UNPREDICTABLE behavior, see [Crossing a page boundary with different memory types or Shareability attributes on page K1-5465](#).

- If the accesses of an instruction that causes multiple accesses to any type of Device memory cross a 4KB address boundary then behavior is CONSTRAINED UNPREDICTABLE and [Crossing a 4KB boundary with a Device access on page K1-5466](#) describes the permitted behaviors.

———— **Note** —————

- The boundary referred to is between two Device memory regions that are both of 4KB and aligned to 4KB.
- This restriction means it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.
- ARM expects this restriction to constrain the placing of volatile memory devices in the system memory map, rather than expecting a compiler to be aware of the alignment of memory accesses.

E2.9 Mismatched memory attributes

In the ARMv8 architecture mismatched memory attributes are controlled by privileged software. For more information, see [Chapter G4 The AArch32 Virtual Memory System Architecture](#).

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

———— **Note** ————

The terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:

- Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
 - A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
 - Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
- There might be a loss of coherency when multiple agents attempt to access a memory location.
- There might be a loss of properties derived from the memory type, as described in later bullets in this section.
- If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
- Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.

The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:

- Prohibition of speculative read accesses.
- Prohibition on Gathering.
- Prohibition on Re-ordering.

For the following situations, when a physical memory location is accessed with mismatched attributes, a more restrictive set of behaviors applies. The description of each situation also describes the behaviors that apply:

1. If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.
2. Any agent that reads that memory location using the same common definition of the Shareability and Cacheability attributes is guaranteed to access it coherently, to the extent required by that common definition of the memory attributes, only if all of the following conditions are met:
 - All aliases to the memory location with write permission both use a common definition of the Shareability and Cacheability attributes for the memory location, and either:
 - Have the Inner Cacheability attribute the same as the Outer Cacheability attribute.
 - In the Non-secure PL1&0 translation regime, have [HCR2.MI0CNCE](#) set to 0.
 - All aliases to a memory location use a definition of the Shareability attributes that encompasses all the agents with permission to access the location.

3. The possible software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
 - Any Device memory type.
 - Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties derived from the memory type when multiple agents attempt to access the memory location.
- Possible reordering of memory transactions to the same memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting DMB barrier instructions between accesses to the same memory location that might use different attributes.

Where there is a loss of the uniprocessor semantics, ordering, or coherency, the following approaches can be used:

1. If the mismatched attributes for a memory location all assign the same Shareability attribute to the location, any loss of uniprocessor semantics, ordering, or coherency within a Shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the ordering or coherency of cacheable locations between agents in different shareability domains. This means:
 - Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.
 - After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.
 - Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.
 - Executing a DMB barrier instruction, with scope that applies to the common Shareability of the accesses, between any accesses to the same memory location that use different attributes.

———— **Note** ————

In AArch32 state, cache maintenance instructions can only be accessed from an Exception level that is higher than EL0, and therefore require a system call. For information on system calls, see [Exception-generating and exception-handling instructions on page F1-2386](#). For information about the AArch32 cache maintenance instructions, see [AArch32 cache and branch predictor support on page G3-3989](#).

In all cases:

- Location refers to any byte within the current coherency granule.
- A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
- In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see [Ordering of cache and branch predictor maintenance instructions on page G3-4007](#).

———— **Note** ————

With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

2. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different Shareability attributes, then ordering and coherency are guaranteed only if:
 - Each PE that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.
 - A DMB barrier with scope that covers the full Shareability of the accesses is placed between any accesses to the same memory location that use different attributes.

———— **Note** —————

The Note in rule 1 of this list, about possible race conditions, also applies to this rule.

—————

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.

E2.10 Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

———— **Note** ————

Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table E2-6 shows the synchronization primitives and the associated CLREX instruction.

Table E2-6 Synchronization primitives and associated instruction

| Function | A32/T32 Instruction |
|-----------------|---------------------|
| Load-Exclusive | |
| Byte | LDREXB, LDAEXB |
| Halfword | LDREXH, LDAEXH |
| Word | LDREX, LDAEX |
| Doubleword | LDREXD, LDAEXD |
| Store-Exclusive | |
| Byte | STREXB, STLEXB |
| Halfword | STREXH, STLEXH |
| Word | STREX, STLEX |
| Doubleword | STREXD, STLEXD |
| Clear-Exclusive | CLREX |

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address x is:

- The Load-Exclusive instruction reads a value from memory address x .
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address x only if no other observer, process, or thread has performed a more recent store to address x . The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block on page E2-2361*. A Store-Exclusive instruction to any address in the marked block clears the marking.

———— **Note** ————

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

The following sections give more information:

- *Exclusive access instructions and Non-shareable memory locations on page E2-2356.*
- *Exclusive access instructions and shareable memory locations on page E2-2358.*
- *Marking and the size of the marked memory block on page E2-2361.*

- [Context switch support on page E2-2361.](#)
- [Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2362.](#)
- [Use of WFE and SEV instructions by spin-locks on page E2-2364.](#)

E2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations for which the Shareability attribute is Non-shareable, the exclusive access instructions rely on a *local monitor* that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
 - If the store took place the status value is 0.
 - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a physical address that is not marked as Exclusive Access by its local monitor and that local monitor is in the Exclusive Access state it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is marked as Exclusive Access by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

[Figure E2-4 on page E2-2357](#) shows the state machine for the local monitor and the effect of each of the operations shown in the figure.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure E2-4 Local monitor state machine diagram

For more information about marking see [Marking and the size of the marked memory block](#) on page E2-2361.

———— **Note** ————

For the local monitor state machine, as shown in [Figure E2-4](#):

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction, by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the Store or StoreExcl is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in [Figure E2-4](#).

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in [Figure E2-4](#).
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in [Figure E2-4](#) must not indefinitely delay forward progress of execution.

E2.10.2 Exclusive access instructions and shareable memory locations

In the context of this section, a shareable memory location is a memory location that has, or is treated as if it has, a Shareability attribute of Inner Shareable or Outer Shareable.

For shareable memory locations, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations on page E2-2356*, except that for shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
 - Updating memory.
 - Returning a status value of 0.

The local monitor can ignore accesses from other PEs in the system.

- A *global monitor* that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the Shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
 - Can hold at least one marked block.
 - Maintains a state machine for each marked block it can hold.

———— **Note** —————

For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is CONstrained UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions on page E2-2362*.

———— **Note** —————

The global monitor can either reside in a block that is part of the hardware on which the PE executes or exist as a secondary monitor at the memory interfaces. The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For shareable memory locations, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

———— **Note** —————

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:

- Inner Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hint and not transient.

- Outer Shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hint and Write allocation hints and not transient.

The set of memory types that support atomic instructions must include all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of:

- `DFSR.STATUS = 0b110101` when using the Long-descriptor translation table format. The fault can also be reported in the `HSR.ISS[5:0]` field for exceptions to Hyp mode.
- `DFSR.FS = 0b110101` when using the Short-descriptor translation table format.

If the IMPLEMENTATION DEFINED MMU fault is generated for the Non-secure PL1&0 translation regime then:

- If the fault is generated because of the memory type defined in the first stage of translation, or if the second stage of translation is disabled, then this is a first stage fault and the exception is taken to EL1.
- Otherwise, the fault is a second stage fault and the exception is taken to EL2.

The priority of this fault is IMPLEMENTATION DEFINED.

- The instruction is treated as a NOP.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by an ARM PE is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global monitor

A Load-Exclusive instruction from shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access can also cause the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

———— Note —————

The global monitor only supports a single outstanding exclusive access to shareable memory for each PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
 - A status value of 0 is returned to a register to acknowledge the successful store.
 - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
 - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
 - A status value of 1 is returned to a register to indicate that the store failed.
 - The global monitor is not affected and remains in Open Access state for the requesting PE.

- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
 - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
 - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to shareable memory by PE(n) can respond to all the shareable memory accesses visible to it. This means it responds to:

- Accesses generated by PE(n).
- Accesses generated by the other observers in the Shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see [Wait For Event and Send Event on page G1-3872](#).

Figure E2-5 shows the state machine for PE(n) in a global monitor.

‡StoreExc1(Marked_address,!n) clears the monitor only if the StoreExc1 updates memory

Operations marked * are possible alternative IMPLEMENTATION DEFINED options.

In the diagram: LoadExc1 represents any Load-Exclusive instruction
 StoreExc1 represents any Store-Exclusive instruction
 Store represents any other store instruction.

Any LoadExc1 operation updates the marked address to the most significant bits of the address x used for the operation.

Figure E2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking see [Marking and the size of the marked memory block on page E2-2361](#).

Note

For the global monitor state machine, as shown in [Figure E2-5 on page E2-2360](#):

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, [Figure E2-5 on page E2-2360](#) only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
 - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
 - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

E2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a Load-Exclusive instruction is executed, a marked block of size 2^a bytes is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. The size of the marked memory block is called the *Exclusives reservation granule*. The Exclusives reservation granule is IMPLEMENTATION DEFINED in the range 4 - 512 words.

Note

This definition means that the Exclusives reservation granule is:

- 4 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

For example, in an implementation where a is 4, a successful LDREXB of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

In some implementations the CTR identifies the Exclusives reservation granule, see [CTR](#). Otherwise, software must assume that the maximum Exclusives reservation granule, 512 words, is implemented.

E2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a CLREX instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

E2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair. To support different implementations of these functions, software must follow the notes and restrictions given in this subsection.

The following notes describe use of a Load-Exclusive/ Store-Exclusive pair, LoadExc1/StoreExc1, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in [Table E2-6 on page E2-2355](#). In this context, a LoadExc1/StoreExc1 pair comprises two instructions in the same thread of execution:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target virtual address of a StoreExc1 is different from the virtual address of the preceding LoadExc1 instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

————— **Note** —————
This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with mismatched addresses, and fail for other instances of a LoadExc1/StoreExc1 pair with mismatched addresses.
 - The data at the address accessed by the LoadExc1, and at the address accessed by the StoreExc1, is UNKNOWN.

This means software can rely on a LoadExc1/StoreExc1 pair to eventually succeed only if the LoadExc1 and the StoreExc1 are executed with the same virtual address.
- If two StoreExc1 instructions are executed without an intervening LoadExc1 instruction the second StoreExc1 instruction returns a status value of 1. This means that:
 - ARM recommends that, in a given thread of execution, every StoreExc1 instruction has a preceding LoadExc1 instruction associated with it.It is not necessary for every LoadExc1 instruction to have a subsequent StoreExc1 instruction.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a StoreExc1 instruction is the same as the transaction size of the preceding LoadExc1 instruction executed in that thread. If the transaction size of a StoreExc1 instruction is different from the preceding LoadExc1 instruction in the same thread of execution, behavior can be CONSTRAINED UNPREDICTABLE with the following behavior:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

————— **Note** —————
This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with mismatched transaction sizes, and fail for other instances of a LoadExc1/StoreExc1 pair with mismatched transaction sizes.
 - The block of data of the size of the larger of the transaction sizes used by the LoadExc1/StoreExc1 pair at the address accessed by the LoadExc1/StoreExc1 pair, is UNKNOWN.

This means software can rely on a LoadExc1/StoreExc1 pair to eventually succeed only if the LoadExc1 and the StoreExc1 have the same transaction size.
- LoadExc1/StoreExc1 loops are guaranteed to make forward progress only if, for any LoadExc1/StoreExc1 loop within a single thread of execution, the software meets all of the following conditions:
 - 1 Between the Load-Exclusive and the Store-Exclusive, there are no explicit memory accesses, preloads, direct or indirect System register writes, address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.

- 2 Between the Store-Exclusive returning a failing result and the retry of the corresponding Load-Exclusive:
- There are no stores or PLDW instructions to any address within the Exclusives reservation granule accessed by the Store-Exclusive.
 - There are no loads or preloads to any address within the Exclusives reservation granule accessed by the Store-Exclusive that use a different VA alias to that address.
 - There are no direct or indirect System register writes, other than changes to the flag fields in the **CPSR** or **FPSCR**, caused by data processing or comparison instructions.
 - There are no direct or indirect address translation instructions, cache or TLB maintenance instructions, exception generating instructions, exception returns, or indirect branches.
 - All loads and stores are to a block of contiguous virtual memory of not more than 512 bytes in size.

The exclusive monitor can be cleared at any time without an application-related cause, provided that such clearing is not systematically repeated so as to prevent the forward progress in finite time of at least one of the threads that is accessing the exclusive monitor.

- Implementations can benefit from keeping the LoadExc1 and StoreExc1 operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the LoadExc1 instruction and the StoreExc1 instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between LoadExc1 and StoreExc1 instructions in a single thread of execution.
 - The architecture sets an upper limit of 2048 bytes on the Exclusives reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.
 - After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.
 - For the memory location accessed by a LoadExc1/StoreExc1 pair, if the memory attributes for a StoreExc1 instruction are different from the memory attributes for the preceding LoadExc1 instruction in the same thread of execution, behavior is CONstrained UNPREDICTABLE. Where this occurs because the translation of the accessed address changes between the LoadExc1 instruction and the StoreExc1 instruction, the CONstrained UNPREDICTABLE behavior is as follows:
 - The StoreExc1 either passes or fails, and the status value returned by the StoreExc1 is UNKNOWN.

———— **Note** —————

This means the StoreExc1 might pass for some instances of a LoadExc1/StoreExc1 pair with changed memory attributes, and fail for other instances of a LoadExc1/StoreExc1 pair with changed memory attributes.

—————

 - The data at the address accessed by the StoreExc1 is UNKNOWN.
- **Note** —————
- Another bullet point in this list covers the case where the memory attributes of a LoadExc1/StoreExc1 pair differ as a result of using different virtual addresses with different attributes that point to the same physical address.
-
- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is CONstrained UNPREDICTABLE, and the instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same Shareability domain as the PE executing the cache maintenance instruction, as determined by the Shareability domain of the address being maintained.

———— **Note** —————

ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

- If the mapping of the virtual to physical address is changed between the LoadExc1 instruction and the StoreExc1 instruction, and the change is performed using a break-before-make sequence as described in [Using break-before-make when updating translation table entries on page G4-4094](#), if the StoreExc1 is performed after another write to the same physical address as the StoreExc1, and that other write was performed after the old translation was properly invalidated and that invalidation was properly synchronized, then the StoreExc1 will not pass its monitor check.

———— **Note** —————

ARM expects that, in many implementations, either:

- The TLB invalidation will clear either the local or global monitor.
- The physical address will be checked between the LoadExc1 and StoreExc1.

———— **Note** —————

In the event of repeatedly-contending LoadExc1/StoreExc1 instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

E2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, WFE, SEV, SEVL, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in [Wait For Event and Send Event on page G1-3872](#). However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

———— **Note** —————

This is equivalent to issuing an SEVL instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an SEV instruction after clearing a spinlock.

Part F

The AArch32 Instruction Sets

Chapter F1

The AArch32 Instruction Sets Overview

This chapter describes the T32 and A32 instruction sets. It contains the following sections:

- *Support for instructions in different versions of the ARM architecture* on page F1-2368.
- *Unified Assembler Language* on page F1-2369.
- *Branch instructions* on page F1-2371.
- *Data-processing instructions* on page F1-2372.
- *PSTATE and banked register access instructions* on page F1-2380.
- *Load/store instructions* on page F1-2381.
- *Load/store multiple instructions* on page F1-2384.
- *Miscellaneous instructions* on page F1-2385.
- *Exception-generating and exception-handling instructions* on page F1-2386.
- *System register access instructions* on page F1-2387.
- *Advanced SIMD and floating-point load/store instructions* on page F1-2388.
- *Advanced SIMD and floating-point register transfer instructions* on page F1-2390.
- *Advanced SIMD data-processing instructions* on page F1-2391.
- *Floating-point data-processing instructions* on page F1-2399.

F1.1 Support for instructions in different versions of the ARM architecture

This manual describes the ARM AArch32 instruction sets, T32 and A32, for the ARMv8 architecture. Therefore, it indicates how any options or extensions in the ARMv8 architecture affect the available instructions. Also, [Appendix K5 ARMv8 Changes to the T32 and A32 Instruction Sets](#) provides information for those migrating from earlier versions of the architecture.

This manual does not provide any information about which T32 and A32 instructions were supported in specific earlier versions of the architecture. For this information, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F1.2 Unified Assembler Language

This manual uses the ARM *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all T32 and A32 instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier ARM assembly language mnemonics are still supported as synonyms, as described in the instruction details.

———— **Note** —————

Most earlier T32 assembly language mnemonics are *not* supported.

UAL includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an `ADD R0, R1, R2` instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

F1.2.1 Conditional instructions

For maximum portability of UAL assembly language between the T32 and A32 instruction sets, ARM recommends that:

- IT instructions are written before conditional instructions in the correct way for the T32 instruction set.
- When assembling to the A32 instruction set, assemblers check that any IT instructions are correct, but do not generate any code for them.

Although other T32 instructions are unconditional, all instructions that are made conditional by an IT instruction must be written with a condition. These conditions must match the conditions imposed by the IT instruction. For example, an `ITEE EQ` instruction imposes the EQ condition on the first two following instructions, and the NE condition on the next two. Those four instructions must be written with EQ, EQ, NE and NE conditions respectively.

Some instructions cannot be made conditional by an IT instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an IT instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding IT instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

———— **Note** —————

ARMv8 deprecates many uses of IT, for performance reasons, see [Partial deprecation of IT on page K5-5531](#). As described in that section, an implementation can include ITD controls that disable those uses of IT, making them UNDEFINED.

F1.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the `PC` or `Align(PC, 4)` value of the instruction. The `PC` value of an instruction is its address plus 4 for a T32 instruction, or plus 8 for an A32 instruction. The `Align(PC, 4)` value of an instruction is its `PC` value ANDed with `0xFFFFF0` to force it to be word-aligned. There is no difference between the `PC` and `Align(PC, 4)` values for an A32 instruction, but there can be for a T32 instruction.

2. Calculate the offset from the PC or `Align(PC, 4)` value of the instruction to the address of the labeled instruction or literal data item.
3. Assemble a *PC-relative* encoding of the instruction, that is, one that reads its PC or `Align(PC, 4)` value and adds the calculated offset to form the required address.

———— **Note** ————

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- B, BL, and BLX (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch.
- CBNZ and CBZ. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the PC value of the instruction to form the target address of the branch. They do not support backward branches.
- LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLDW, PLI, and VLDR. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:

+/- Is + or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or - if it is to be subtracted.

<imm> Is the immediate offset.

This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.

- ADR. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

———— **Note** ————

ARM recommends that where possible, software avoids using:

- The alternative syntax for the ADR, LDC, LDR, LDRB, LDRD, LDRH, LDRSB, LDRSH, PLD, PLI, PLDW, and VLDR instructions.
- The encodings of these instructions that subtract 0 from the `Align(PC, 4)` value.

F1.3 Branch instructions

Table F1-1 summarizes the branch instructions in the T32 and A32 instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

Table F1-1 Branch instructions

| Instruction | See | Range, T32 | Range, A32 |
|--|---|----------------|--------------|
| Branch to target address | B on page F5-2607 | ±16MB | ±32MB |
| Compare and Branch on Nonzero, Compare and Branch on Zero | CBNZ, CBZ on page F5-2630 | 0-126 bytes | ^a |
| Call a subroutine | BL, BLX (immediate) on page F5-2623 | ±16MB | ±32MB |
| Call a subroutine, change instruction set ^b | BL, BLX (immediate) on page F5-2623 | ±16MB | ±32MB |
| Call a subroutine, optionally change instruction set | BLX (register) on page F5-2625 | Any | Any |
| Branch to target address, change instruction set | BX on page F5-2627 | Any | Any |
| Change to Jazelle state | BXJ on page F5-2629 | - | - |
| Table Branch (byte offsets) | TBB, TBH on page F5-3143 | 0-510 bytes | ^a |
| Table Branch (halfword offsets) | | 0-131070 bytes | |

a. These instructions do not exist in the A32 instruction set.

b. The range is determined by the instruction set of the BLX instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by LDR, LDM and data-processing instructions. For details see [Load/store instructions on page F1-2381](#), [Load/store multiple instructions on page F1-2384](#), [Standard data-processing instructions on page F1-2372](#), and [Shift instructions on page F1-2374](#).

In addition to the branch instructions shown in Table F1-1:

- In the A32 instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see [Data-processing instructions on page F1-2372](#).
- In the T32 and A32 instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see [Load/store instructions on page F1-2381](#).

F1.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- [Standard data-processing instructions](#).
These instructions perform basic data-processing operations, and share a common format with some variations.
- [Shift instructions on page F1-2374](#).
- [Multiply instructions on page F1-2374](#).
- [Saturating instructions on page F1-2376](#).
- [Saturating addition and subtraction instructions on page F1-2376](#).
- [Packing and unpacking instructions on page F1-2377](#).
- [Parallel addition and subtraction instructions on page F1-2378](#).
- [Divide instructions on page F1-2379](#).
- [Miscellaneous data-processing instructions on page F1-2379](#).

For related Advanced SIMD and floating-point instructions see [Advanced SIMD data-processing instructions on page F1-2391](#) and [Floating-point data-processing instructions on page F1-2399](#).

F1.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A *modified immediate constant* that uses 12 bits of the instruction to encode a range of constants. T32 and A32 instructions have slightly different ranges of modified immediate constants. For more information, see [Modified immediate constants in T32 instructions on page F2-2420](#) and [Modified immediate constants in A32 instructions on page F2-2422](#).

If the second operand is another register, it can optionally be shifted in any of the following ways:

| | |
|-----|---|
| LSL | Logical Shift Left by 1-31 bits. |
| LSR | Logical Shift Right by 1-32 bits. |
| ASR | Arithmetic Shift Right by 1-32 bits. |
| ROR | Rotate Right by 1-31 bits. |
| RRX | Rotate Right with Extend. For details see Shift and rotate operations on page E1-2290 . |

In T32 code, the amount to shift by is always a constant encoded in the instruction. In A32 code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than CMN, CMP, TEQ, and TST, the result of the data-processing operation is placed in the destination register. In the A32 instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the T32 instruction set, this is only permitted for some 16-bit forms of the ADD and MOV instructions.

These instructions can optionally set the condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

[Table F1-2 on page F1-2373](#) summarizes the main data-processing instructions in the T32 and A32 instruction sets. Generally, each of these instructions is described in three sections in [Chapter F2 About the T32 and A32 Instruction Descriptions](#), one section for each of the following:

- INSTRUCTION (immediate) where the second operand is a modified immediate constant.
- INSTRUCTION (register) where the second operand is a register, or a register shifted by a constant.
- INSTRUCTION (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the A32 instruction set.

Table F1-2 Standard data-processing instructions

| Instruction | Mnemonic | Notes |
|-----------------------------|----------|--|
| Add with Carry | ADC | - |
| Add | ADD | T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant. |
| Form PC-relative Address | ADR | First operand is the PC. Second operand is an immediate constant. T32 instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction. |
| Bitwise AND | AND | - |
| Bitwise Bit Clear | BIC | - |
| Compare Negative | CMN | Sets flags. Like ADD but with no destination register. |
| Compare | CMP | Sets flags. Like SUB but with no destination register. |
| Bitwise Exclusive OR | EOR | - |
| Copy operand to destination | MOV | Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details see Shift instructions on page F1-2374 . The T32 and A32 instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant. |
| Bitwise NOT | MVN | Has only one operand, with the same options as the second operand in most of these instructions. |
| Bitwise OR NOT | ORN | Not available in the A32 instruction set. |
| Bitwise OR | ORR | - |
| Reverse Subtract | RSB | Subtracts first operand from second operand. This permits subtraction from constants and shifted registers. |
| Reverse Subtract with Carry | RSC | Not available in the T32 instruction set. |
| Subtract with Carry | SBC | - |
| Subtract | SUB | T32 instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant. |
| Test Equivalence | TEQ | Sets flags. Like EOR but with no destination register. |
| Test | TST | Sets flags. Like AND but with no destination register. |

F1.4.2 Shift instructions

Table F1-3 lists the shift instructions in the T32 and A32 instruction sets.

Table F1-3 Shift instructions

| Instruction | See |
|--------------------------|--|
| Arithmetic Shift Right | <i>ASR (immediate)</i> on page F5-2599 <i>ASR (register)</i> on page F5-2601 <i>ASRS (immediate)</i> on page F5-2603 <i>ASRS (register)</i> on page F5-2605 |
| Logical Shift Left | <i>LSL (immediate)</i> on page F5-2788 <i>LSL (register)</i> on page F5-2790 <i>LSLS (immediate)</i> on page F5-2792 <i>LSLS (register)</i> on page F5-2794 |
| Logical Shift Right | <i>LSR (immediate)</i> on page F5-2796 <i>LSR (register)</i> on page F5-2798 <i>LSRS (immediate)</i> on page F5-2800 <i>LSRS (register)</i> on page F5-2802 |
| Rotate Right | <i>ROR (immediate)</i> on page F5-2921 <i>ROR (register)</i> on page F5-2923 <i>RORS (immediate)</i> on page F5-2925 <i>RORS (register)</i> on page F5-2927 |
| Rotate Right with Extend | <i>RRX</i> on page F5-2929 <i>RRXS</i> on page F5-2931 |

In the A32 instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

F1.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are the same whether the operands are signed or unsigned.

- [Table F1-4](#) summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.
 The least significant 32 bits of the result are used. More significant bits are discarded.
- [Table F1-5 on page F1-2375](#) summarizes the signed multiply instructions.
- [Table F1-6 on page F1-2375](#) summarizes the unsigned multiply instructions.

Table F1-4 General multiply instructions

| Instruction | See | Operation (number of bits) |
|-----------------------|----------------------------------|----------------------------|
| Multiply Accumulate | <i>MLA, MLAS</i> on page F5-2808 | $32 = 32 + 32 \times 32$ |
| Multiply and Subtract | <i>MLS</i> on page F5-2810 | $32 = 32 - 32 \times 32$ |
| Multiply | <i>MUL, MULS</i> on page F5-2845 | $32 = 32 \times 32$ |

Table F1-5 Signed multiply instructions

| Instruction | See | Operation (number of bits) |
|--|---|---|
| Signed Multiply Accumulate (halfwords) | <i>SMLABB, SMLABT, SMLATB, SMLATT</i> on page F5-2985 | $32 = 32 + 16 \times 16$ |
| Signed Multiply Accumulate Dual | <i>SMLAD, SMLADX</i> on page F5-2987 | $32 = 32 + 16 \times 16 + 16 \times 16$ |
| Signed Multiply Accumulate Long | <i>SMLAL, SMLALS</i> on page F5-2989 | $64 = 64 + 32 \times 32$ |
| Signed Multiply Accumulate Long (halfwords) | <i>SMLALBB, SMLALBT, SMLALTB, SMLALTT</i> on page F5-2991 | $64 = 64 + 16 \times 16$ |
| Signed Multiply Accumulate Long Dual | <i>SMLALD, SMLALDX</i> on page F5-2994 | $64 = 64 + 16 \times 16 + 16 \times 16$ |
| Signed Multiply Accumulate (word by halfword) | <i>SMLAWB, SMLAWT</i> on page F5-2996 | $32 = 32 + 32 \times 16^a$ |
| Signed Multiply Subtract Dual | <i>SMLS D, SMLS DX</i> on page F5-2998 | $32 = 32 + 16 \times 16 - 16 \times 16$ |
| Signed Multiply Subtract Long Dual | <i>SMLS LD, SMLS LDX</i> on page F5-3000 | $64 = 64 + 16 \times 16 - 16 \times 16$ |
| Signed Most Significant Word Multiply Accumulate | <i>SMMLA, SMMLAR</i> on page F5-3002 | $32 = 32 + 32 \times 32^b$ |
| Signed Most Significant Word Multiply Subtract | <i>SMMLS, SMMLSR</i> on page F5-3004 | $32 = 32 - 32 \times 32^b$ |
| Signed Most Significant Word Multiply | <i>SMMUL, SMMULR</i> on page F5-3006 | $32 = 32 \times 32^b$ |
| Signed Dual Multiply Add | <i>SMUAD, SMUADX</i> on page F5-3008 | $32 = 16 \times 16 + 16 \times 16$ |
| Signed Multiply (halfwords) | <i>SMULBB, SMULBT, SMULTB, SMULTT</i> on page F5-3010 | $32 = 16 \times 16$ |
| Signed Multiply Long | <i>SMULL, SMULLS</i> on page F5-3012 | $64 = 32 \times 32$ |
| Signed Multiply (word by halfword) | <i>SMULWB, SMULWT</i> on page F5-3014 | $32 = 32 \times 16^a$ |
| Signed Dual Multiply Subtract | <i>SMUSD, SMUSDX</i> on page F5-3016 | $32 = 16 \times 16 - 16 \times 16$ |

a. The most significant 32 bits of the 48-bit product are used. Less significant bits are discarded.

b. The most significant 32 bits of the 64-bit product are used. Less significant bits are discarded.

Table F1-6 Unsigned multiply instructions

| Instruction | See | Operation (number of bits) |
|--|--------------------------------------|-----------------------------------|
| Unsigned Multiply Accumulate Accumulate Long | <i>UMAAL</i> on page F5-3178 | $64 = 32 + 32 + 32 \times 32$ |
| Unsigned Multiply Accumulate Long | <i>UMLAL, UMLALS</i> on page F5-3180 | $64 = 64 + 32 \times 32$ |
| Unsigned Multiply Long | <i>UMULL, UMULLS</i> on page F5-3182 | $64 = 32 \times 32$ |

F1.4.4 Saturating instructions

Table F1-7 lists the saturating instructions in the T32 and A32 instruction sets. For more information, see [Pseudocode description of saturation on page E1-2291](#).

Table F1-7 Saturating instructions

| Instruction | See | Operation |
|----------------------|--|---|
| Signed Saturate | SSAT on page F5-3022 | Saturates optionally shifted 32-bit value to selected range |
| Signed Saturate 16 | SSAT16 on page F5-3024 | Saturates two 16-bit values to selected range |
| Unsigned Saturate | USAT on page F5-3200 | Saturates optionally shifted 32-bit value to selected range |
| Unsigned Saturate 16 | USAT16 on page F5-3202 | Saturates two 16-bit values to selected range |

F1.4.5 Saturating addition and subtraction instructions

Table F1-8 lists the saturating addition and subtraction instructions in the T32 and A32 instruction sets. For more information, see [Pseudocode description of saturation on page E1-2291](#).

Table F1-8 Saturating addition and subtraction instructions

| Instruction | See | Operation |
|--------------------------------|---------------------------------------|--|
| Saturating Add | QADD on page F5-2891 | Add, saturating result to the 32-bit signed integer range |
| Saturating Subtract | QSUB on page F5-2904 | Subtract, saturating result to the 32-bit signed integer range |
| Saturating Double and Add | QADD on page F5-2891 | Doubles one value and adds a second value, saturating the doubling and the addition to the 32-bit signed integer range |
| Saturating Double and Subtract | QDSUB on page F5-2900 | Doubles one value and subtracts the result from a second value, saturating the doubling and the subtraction to the 32-bit signed integer range |

F1.4.6 Packing and unpacking instructions

Table F1-9 lists the packing and unpacking instructions in the T32 and A32 instruction sets.

Table F1-9 Packing and unpacking instructions

| Instruction | See | Operation |
|----------------------------------|--|----------------------------------|
| Pack Halfword | PKHBT, PKHTB on page F5-2867 | Combine halfwords |
| Signed Extend and Add Byte | SXTAB on page F5-3131 | Extend 8 bits to 32 and add |
| Signed Extend and Add Byte 16 | SXTAB16 on page F5-3133 | Dual extend 8 bits to 16 and add |
| Signed Extend and Add Halfword | SXTAH on page F5-3135 | Extend 16 bits to 32 and add |
| Signed Extend Byte | SXTB on page F5-3137 | Extend 8 bits to 32 |
| Signed Extend Byte 16 | SXTB16 on page F5-3139 | Dual extend 8 bits to 16 |
| Signed Extend Halfword | SXTH on page F5-3141 | Extend 16 bits to 32 |
| Unsigned Extend and Add Byte | UXTAB on page F5-3210 | Extend 8 bits to 32 and add |
| Unsigned Extend and Add Byte 16 | UXTAB16 on page F5-3212 | Dual extend 8 bits to 16 and add |
| Unsigned Extend and Add Halfword | UXTAH on page F5-3214 | Extend 16 bits to 32 and add |
| Unsigned Extend Byte | UXTB on page F5-3216 | Extend 8 bits to 32 |
| Unsigned Extend Byte 16 | UXTB16 on page F5-3218 | Dual extend 8 bits to 16 |
| Unsigned Extend Halfword | UXTH on page F5-3220 | Extend 16 bits to 32 |

F1.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the general-purpose registers.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

| | |
|----|--|
| S | Signed arithmetic modulo 2^8 or 2^{16} . |
| Q | Signed saturating arithmetic. |
| SH | Signed arithmetic, halving the results. |
| U | Unsigned arithmetic modulo 2^8 or 2^{16} . |
| UQ | Unsigned saturating arithmetic. |
| UH | Unsigned arithmetic, halving the results. |

The main instruction mnemonics are as follows:

| | |
|-------|---|
| ADD16 | Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result. |
| ASX | Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords. |
| SAX | Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords. |
| SUB16 | Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result. |
| ADD8 | Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result. |
| SUB8 | Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result. |

The instruction set permits all 36 combinations of prefix and main instruction operand, as [Table F1-10](#) shows.

See also [Advanced SIMD parallel addition and subtraction on page F1-2392](#).

Table F1-10 Parallel addition and subtraction instructions

| Main instruction | Signed | Saturating | Signed halving | Unsigned | Unsigned saturating | Unsigned halving |
|-------------------------------------|--------|------------|----------------|----------|---------------------|------------------|
| ADD16, add, two halfwords | SADD16 | QADD16 | SHADD16 | UADD16 | UQADD16 | UHADD16 |
| ASX, add and subtract with exchange | SASX | QASX | SHASX | UASX | UQASX | UHASX |
| SAX, subtract and add with exchange | SSAX | QSAX | SHSAX | USAX | UQSAX | UHSAX |
| SUB16, subtract, two halfwords | SSUB16 | QSUB16 | SHSUB16 | USUB16 | UQSUB16 | UHSUB16 |
| ADD8, add, four bytes | SADD8 | QADD8 | SHADD8 | UADD8 | UQADD8 | UHADD8 |
| SUB8, subtract, four bytes | SSUB8 | QSUB8 | SHSUB8 | USUB8 | UQSUB8 | UHSUB8 |

F1.4.8 Divide instructions

In ARMv8, signed and unsigned integer divide instructions are included in both the T32 instruction set and the A32 instruction set. For more information about their implementation in previous versions of the ARM architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

For descriptions of the instructions see:

- [SDIV on page F5-2962](#).
- [UDIV on page F5-3164](#).

For the SDIV and UDIV instructions, divide-by-zero always returns a zero result.

The `ID_ISAR0.Divide_instrs` field indicates the level of support for these instructions. The field value of `0b0010` indicates they are implemented in both the T32 and A32 instruction sets.

F1.4.9 Miscellaneous data-processing instructions

[Table F1-11](#) lists the miscellaneous data-processing instructions in the T32 and A32 instruction sets. Immediate values in these instructions are simple binary numbers.

Table F1-11 Miscellaneous data-processing instructions

| Instruction | See | Notes |
|---|--|--|
| BitField Clear | BFC on page F5-2610 | - |
| BitField Insert | BFI on page F5-2612 | - |
| Count Leading Zeros | CLZ on page F5-2632 | - |
| Move Top | MOVT on page F5-2824 | Moves 16-bit immediate value to top halfword. Bottom halfword unchanged. |
| Reverse Bits | RBIT on page F5-2910 | - |
| Byte-Reverse Word | REV on page F5-2912 | - |
| Byte-Reverse Packed Halfword | REV16 on page F5-2914 | - |
| Byte-Reverse Signed Halfword | REVSH on page F5-2916 | - |
| Signed BitField Extract | SBFX on page F5-2960 | - |
| Select Bytes using GE flags | SEL on page F5-2964 | - |
| Unsigned BitField Extract | UBFX on page F5-3160 | - |
| Unsigned Sum of Absolute Differences | USAD8 on page F5-3196 | - |
| Unsigned Sum of Absolute Differences and Accumulate | USADA8 on page F5-3198 | - |

F1.5 PSTATE and banked register access instructions

These instructions transfer PE state information to or from a general-purpose register.

F1.5.1 PSTATE access instructions

PSTATE holds process state information, see *Process state, PSTATE* on page E1-2294. In AArch32 state:

- At EL1 or higher, **PSTATE** is accessible using the *Current Program Status Register (CPSR)*.
- At EL0, a subset of the **CPSR** is accessible as the *Application Program Status Register (APSR)*.
- On taking an exception, the contents of the **CPSR** are copied to the *Saved Program Status Register (SPSR)* of the mode from which the exception is taken.

The MRS and MSR instructions move the contents of the **CPSR**, **APSR**, or the **SPSR** of the current mode to or from a general-purpose register, see:

- *MRS* on page F5-2830.
- *MSR (immediate)* on page F5-2840.
- *MSR (register)* on page F5-2842.

When executed at EL0, MRS and MSR instructions can only access the **APSR**.

The **PSTATE** condition flags, **PSTATE**.{N, Z, C, V} are set by the execution of data-processing instructions, and can control the execution of conditional instructions. However, software can set the condition flags explicitly using the MSR instruction, and can read the current state of the condition flags explicitly using the MRS instruction.

In addition, at EL1 or higher, software can use the CPS instruction to change the **PSTATE**.M field and the **PSTATE**.{A, I, F} interrupt mask bits, see *CPS, CPSID, CPSIE* on page F5-2645.

F1.5.2 Banked register access instructions

At EL1 or higher, the MRS (Banked register) and MSR (Banked register) instructions move the contents of a Banked general-purpose register, the **SPSR**, or the **ELR_hyp**, to or from a general-purpose register. See:

- *MRS (Banked register)* on page F5-2832.
- *MSR (Banked register)* on page F5-2836.

F1.6 Load/store instructions

Table F1-12 summarizes the general-purpose register load/store instructions in the T32 and A32 instruction sets. Some of these instructions can also operate on the PC. See also:

- [Load/store multiple instructions on page F1-2384](#).
- [Synchronization and semaphores on page E2-2355](#), for more information about the Load-Exclusive and Store-Exclusive instructions.
- [Load-Acquire, Store-Release on page E2-2338](#), for more information about the Load-Acquire/Store-Release and Load-Acquire Exclusive/Store-Release Exclusive instructions.
- [Advanced SIMD and floating-point load/store instructions on page F1-2388](#).

Load/store instructions have several options for addressing memory. For more information, see [Addressing modes on page F1-2382](#).

Table F1-12 Load/store instructions

| Data type | Load | Store | Unprivileged | | Exclusive | | Load-Acquire | Store-Release | Exclusive | |
|--------------------------|-------|-------|--------------|-------|-----------|--------|--------------|---------------|--------------|---------------|
| | | | Load | Store | Load | Store | | | Load-Acquire | Store-Release |
| 32-bit word | LDR | STR | LDRT | STRT | LDREX | STREX | LDA | STL | LDAEX | STLEX |
| 16-bit halfword | - | STRH | - | STRHT | - | STREXH | LDAH | STLH | LDAEXH | STLEXH |
| 16-bit unsigned halfword | LDRH | - | LDRHT | - | LDREXH | - | - | - | - | - |
| 16-bit signed halfword | LDRSH | - | LDRSHT | - | - | - | - | - | - | - |
| 8-bit byte | - | STRB | - | STRBT | - | STREXB | LDAB | STLB | LDAEXB | STLEXB |
| 8-bit unsigned byte | LDRB | - | LDRBT | - | LDREXB | - | - | - | - | - |
| 8-bit signed byte | LDRSB | - | LDRSBT | - | - | - | - | - | - | - |
| Two 32-bit words | LDRD | STRD | - | - | - | - | - | - | - | - |
| 64-bit doubleword | - | - | - | - | LDREXD | STREXD | - | - | LDAEXD | STLEXD |

F1.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

F1.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

F1.6.3 Load unprivileged and Store unprivileged

When executing at EL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at EL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at EL0. In particular, the instructions make unprivileged memory accesses.

———— **Note** —————

As described in [Security state, Exception levels, and AArch32 execution privilege on page G1-3792](#), execution at PL1 describes all of the following:

- Execution at Non-secure EL1 using AArch32.
- Execution at Secure EL1 using AArch32 when EL3 is not implemented.
- Execution at Secure EL1 using AArch32 when EL3 is implemented and is using AArch64.
- Execution at Secure EL3 when EL3 is implemented and is using AArch32.

The Load unprivileged and Store unprivileged instructions are CONstrained UNPREDICTABLE if executed at EL2, see [Execution of Load/Store unprivileged instructions in Hyp mode on page K1-5475](#).

For more information about execution privilege, see [Access permissions on page G4-4068](#).

F1.6.4 Load-Exclusive and Store-Exclusive

Load-Exclusive and Store-Exclusive instructions provide shared memory synchronization. For more information, see [Synchronization and semaphores on page E2-2355](#).

F1.6.5 Load-Acquire and Store-Release

Load-Acquire and Store-Release instructions provide memory barriers. Load-Acquire Exclusive and Store-Release Exclusive instructions provide memory barriers with shared memory synchronization. For more information, see [Load-Acquire, Store-Release on page E2-2338](#).

F1.6.6 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the general-purpose registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This provides PC-relative addressing for position-independent code. Instructions marked (literal) in their title in [Chapter F2 About the T32 and A32 Instruction Descriptions](#) are PC-relative loads.

The offset takes one of three formats:

| | |
|------------------------|--|
| Immediate | The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers. |
| Register | The offset is a value from a general-purpose register. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data. |
| Scaled register | The offset is a general-purpose register, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element. |

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

- Offset** The offset is added to or subtracted from the base register to form the memory address.
- Pre-indexed** The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.
- Post-indexed** The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

———— **Note** —————

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See [Chapter F2 About the T32 and A32 Instruction Descriptions](#) for full details for each instruction.

F1.7 Load/store multiple instructions

Load Multiple instructions load from memory a subset, or possibly all, of the general-purpose registers and the PC.

Store Multiple instructions store to memory a subset, or possibly all, of the general-purpose registers.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table F1-13 summarizes the load/store multiple instructions in the T32 and A32 instruction sets.

Table F1-13 Load/store multiple instructions

| Instruction | See |
|--|---|
| Load Multiple, Increment After or Full Descending | LDM, LDMIA, LDMFD on page F5-2699 |
| Load Multiple, Decrement After or Full Ascending ^a | LMDMA, LDMFA on page F5-2707 |
| Load Multiple, Decrement Before or Empty Ascending | LDMDB, LDMEA on page F5-2709 |
| Load Multiple, Increment Before or Empty Descending ^a | LDMIB, LDMED on page F5-2712 |
| Pop multiple registers off the stack ^b | POP on page F5-2880 |
| Push multiple registers onto the stack ^c | PUSH on page F5-2886 |
| Store Multiple, Increment After or Empty Ascending | STM, STMIA, STMEA on page F5-3049 |
| Store Multiple, Decrement After or Empty Descending ^a | STMDA, STMED on page F5-3055 |
| Store Multiple, Decrement Before or Full Descending | STMDB, STMFD on page F5-3057 |
| Store Multiple, Increment Before or Full Ascending ^a | STMIB, STMFA on page F5-3060 |

a. Not available in the T32 instruction set.

b. This instruction is equivalent to an LDM instruction with the SP as base register, and base register updating.

c. This instruction is equivalent to an STMDB instruction with the SP as base register, and base register updating.

When executing at EL1, variants of the LDM and STM instructions load and store User mode registers. Another system level variant of the LDM instruction performs an exception return.

F1.7.1 Loads to the PC

The LDM, LMDMA, LDMDB, LDMIB, and POP instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the [LoadWritePC\(\)](#) pseudocode function in *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.

F1.8 Miscellaneous instructions

Table F1-14 summarizes the miscellaneous instructions in the T32 and A32 instruction sets.

Table F1-14 Miscellaneous instructions

| Instruction | See |
|-------------------------------------|--|
| Clear-Exclusive | CLREX on page F5-2631 |
| Data Memory Barrier | DMB on page F5-2659 |
| Data Synchronization Barrier | DSB on page F5-2662 |
| Instruction Synchronization Barrier | ISB on page F5-2679 |
| If-Then | IT on page F5-2681 |
| No Operation | NOP on page F5-2854 |
| Preload Data | PLD , PLDW (immediate) on page F5-2869 PLD (literal) on page F5-2871 PLD , PLDW (register) on page F5-2873 |
| Preload Instruction | PLI (immediate, literal) on page F5-2875 PLI (register) on page F5-2878 |
| Set Endianness | SETEND on page F5-2966 |
| Send Event | SEV on page F5-2967 |
| Send Event Local | SEVL on page F5-2969 |
| Wait For Event | WFE on page F5-3222 |
| Wait For Interrupt | WFI on page F5-3224 |
| Yield | YIELD on page F5-3226 |

Note

Previous versions of the architecture defined the DBG instruction, that could provide a hint to the debug system, in this group. In ARMv8, this instruction executes as a NOP. ARM deprecates any use of the DBG instruction.

F1.8.1 The Yield instruction

In a *Symmetric Multithreading* (SMT) design, a thread can use the YIELD instruction to give a hint to the PE that it is running on. The YIELD hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

AArch32 state defines a YIELD instruction as a specific NOP (No Operation) hint instruction.

The YIELD instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use YIELD in places where a yield hint is wanted, knowing that it will be treated as a NOP if there is no implementation benefit.

F1.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see [Supervisor Call \(SVC\) exception on page G1-3853](#).
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see [Breakpoint Instruction exceptions on page G2-3935](#).
- In an implementation that includes EL3, when executing at EL1 or higher, the SMC instruction generates a Secure Monitor Call exception. For more information, see [Secure Monitor Call \(SMC\) exception on page G1-3854](#).
- In an implementation that includes EL2, in software executing in a Non-secure EL1 mode, the HVC instruction generates a Hypervisor Call exception. For more information, see [Hypervisor Call \(HVC\) exception on page G1-3855](#).

For an exception taken to an EL1 mode:

- The system level variants of the SUBS and LDM instructions can perform a return from an exception.

———— **Note** —————

The variants of SUBS include MOV_S. See the references to [Subtract \(exception return\)](#), [Move \(exception return\)](#), and [Load Multiple \(exception return\)](#) in [Table F1-15](#) for more information.

- The SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In an implementation that includes EL2, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see [Exception return to an Exception level using AArch32 on page G1-3834](#).

[Table F1-15](#) summarizes the instructions, in the T32 and A32 instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

Table F1-15 Exception-generating and exception-handling instructions

| Instruction | See |
|--|---|
| Supervisor Call | SVC on page F5-3129 |
| Breakpoint | BKPT on page F5-2621 |
| Secure Monitor Call | SMC on page F5-2983 |
| Return From Exception | RFE, RFEDA, RFEDB, RFEIA, RFEIB on page F5-2918 |
| Subtract (exception return) ^a | SUB, SUBS (immediate) on page F5-3114^a |
| Move (exception return) ^a | MOV, MOV_S (register) on page F5-2815^a |
| Hypervisor Call | HVC on page F5-2677 |
| Exception Return | ERET on page F5-2673 |
| Load Multiple (exception return) | LDM (exception return) on page F5-2703 |
| Store Return State | SRS, SRSDA, SRSDB, SRSIA, SRSIB on page F5-3018 |

a. The A32 instruction set includes other instruction forms that can be used for an exception return, that have previously been described as variants of SUBS PC, LR. ARM deprecates any use of these instruction forms.

F1.10 System register access instructions

The System register encoding space is indexed using the parameters { coproc, opc1, CRn, CRm, opc2 }, see [The AArch32 System register interface on page G1-3877](#). This encoding space provides System registers and System instructions. In ARMv8, the only permitted values of coproc are 0b1110 and 0b1111, and the following instructions give access to this encoding space:

- Instructions that transfer data between general-purpose registers and System registers. See:
 - [MCR on page F5-2804](#).
 - [MCRR on page F5-2806](#).
 - [MRC on page F5-2826](#).
 - [MRRC on page F5-2828](#).
- Instructions that load or store from memory to a System register. See:
 - [LDC \(immediate\) on page F5-2695](#).
 - [LDC \(literal\) on page F5-2697](#).
 - [STC on page F5-3032](#).

———— Note —————

The System register encoding space with coproc==0b101x is redefined to provide some of the Advanced SIMD and floating-point functionality. That is, to:

- Initiate a floating-point data-processing operation, see [Floating-point data-processing instructions on page F1-2399](#).
- Transfer data between general-purpose registers and the Advanced SIMD and floating-point registers, see [Advanced SIMD and floating-point register transfer instructions on page F1-2390](#).
- Load or store data to the Advanced SIMD and floating-point registers, see [Advanced SIMD and floating-point load/store instructions on page F1-2388](#).

System register access instructions are part of the instruction stream executed by the PE, and therefore any System register access instruction that cannot be executed by the implementation causes an Undefined Instruction exception. In ARMv8-A and ARMv8-R, the instruction encodings in the System register access instruction encoding space are unallocated, and generate Undefined Instruction exceptions, except for:

- The instructions summarized in this section that access the coproc==0b111x encoding space.
- The instructions in the coproc==0b101x encoding space that are redefined to provide Advanced SIMD and floating-point functionality, as summarized in the Note in this section.

F1.11 Advanced SIMD and floating-point load/store instructions

Table F1-16 summarizes the SIMD and floating-point register file load/store instructions in the Advanced SIMD and floating-point instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see *Element and structure load/store instructions*.

Table F1-16 SIMD and floating-point register file load/store instructions

| Instruction | See | Operation |
|-----------------------|--|---|
| Vector Load Multiple | <i>VLDM</i> , <i>VLDMDB</i> , <i>VLDMIA</i> on page F6-3458 | Load 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Load 1-16 consecutive 32-bit registers, floating-point only. |
| Vector Load Register | <i>VLDR (immediate)</i> on page F6-3463 <i>VLDR (literal)</i> on page F6-3465 | Load one 64-bit register, Advanced SIMD and floating-point. Load one 32-bit register, floating-point only. |
| Vector Store Multiple | <i>VSTM</i> , <i>VSTMDB</i> , <i>VSTMIA</i> on page F6-3744 | Store 1-16 consecutive 64-bit registers, Advanced SIMD and floating-point. Store 1-16 consecutive 32-bit registers, floating-point only. |
| Vector Store Register | <i>VSTR</i> on page F6-3749 | Store one 64-bit register, Advanced SIMD and floating-point. Store one 32-bit register, floating-point only. |

F1.11.1 Element and structure load/store instructions

Table F1-17 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see [Figure F1-1 on page F1-2389](#) for an example of de-interleaving. Interleaving is the inverse process.

Table F1-17 Element and structure load/store instructions

| Instruction | See |
|--------------------------|---|
| Load single element | |
| Multiple elements | <i>VLD1 (multiple single elements)</i> on page F6-3424 |
| To one lane | <i>VLD1 (single element to one lane)</i> on page F6-3418 |
| To all lanes | <i>VLD1 (single element to all lanes)</i> on page F6-3421 |
| Load 2-element structure | |
| Multiple structures | <i>VLD2 (multiple 2-element structures)</i> on page F6-3435 |
| To one lane | <i>VLD2 (single 2-element structure to one lane)</i> on page F6-3428 |
| To all lanes | <i>VLD2 (single 2-element structure to all lanes)</i> on page F6-3432 |
| Load 3-element structure | |
| Multiple structures | <i>VLD3 (multiple 3-element structures)</i> on page F6-3445 |
| To one lane | <i>VLD3 (single 3-element structure to one lane)</i> on page F6-3438 |
| To all lanes | <i>VLD3 (single 3-element structure to all lanes)</i> on page F6-3442 |

Table F1-17 Element and structure load/store instructions (continued)

| Instruction | See |
|---------------------------|--|
| Load 4-element structure | |
| Multiple structures | <i>VLD4 (multiple 4-element structures)</i> on page F6-3455 |
| To one lane | <i>VLD4 (single 4-element structure to one lane)</i> on page F6-3448 |
| To all lanes | <i>VLD4 (single 4-element structure to all lanes)</i> on page F6-3452 |
| Store single element | |
| Multiple elements | <i>VST1 (multiple single elements)</i> on page F6-3719 |
| From one lane | <i>VST1 (single element from one lane)</i> on page F6-3716 |
| Store 2-element structure | |

Figure F1-1 shows the de-interleaving of a VLD3.16 (multiple 3-element structures) instruction:

Figure F1-1 De-interleaving an array of 3-element structures

Figure F1-1 shows the VLD3.16 instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, VLD4 and VST4 instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.

F1.12 Advanced SIMD and floating-point register transfer instructions

Table F1-18 summarizes the SIMD and floating-point register file transfer instructions in the Advanced SIMD and floating-point instruction sets. These instructions transfer data between the general-purpose registers and the registers in the SIMD and floating-point register file.

Advanced SIMD vectors, and single-precision and double-precision floating-point registers, are all views of the same register file. For details see *The SIMD and floating-point register file* on page E1-2300.

Table F1-18 SIMD and floating-point register file transfer instructions

| Instruction | See |
|--|--|
| Copy element from general-purpose register to every element of an Advanced SIMD vector | <i>VDUP (general-purpose register)</i> on page F6-3394 |
| Copy byte, halfword, or word from general-purpose register to a register in the SIMD and floating-point register file | <i>VMOV (general-purpose register to scalar)</i> on page F6-3512 |
| Copy byte, halfword, or word from a register in the SIMD and floating-point register file to a general-purpose register | <i>VMOV (scalar to general-purpose register)</i> on page F6-3516 |
| Copy from single-precision floating-point register to general-purpose register, or from general-purpose register to single-precision floating-point register | <i>VMOV (between general-purpose register and single-precision)</i> on page F6-3514 |
| Copy two words from general-purpose registers to consecutive single-precision floating-point registers, or from consecutive single-precision floating-point registers to general-purpose registers | <i>VMOV (between two general-purpose registers and two single-precision registers)</i> on page F6-3518 |
| Copy two words from general-purpose registers to a doubleword register in the SIMD and floating-point register file, or from a doubleword register in the SIMD and floating-point register file to general-purpose registers | <i>VMOV (between two general-purpose registers and a doubleword floating-point register)</i> on page F6-3503 |
| Copy from an Advanced SIMD and floating-point System Register to a general-purpose register | <i>VMRS</i> on page F6-3525 |
| Copy from a general-purpose register to an Advanced SIMD and floating-point System Register | <i>VMSR</i> on page F6-3528 |

F1.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. [Figure F1-2](#) shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

———— **Note** —————

[Figure F1-2](#) and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

Figure F1-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

[Figure F1-3](#) shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

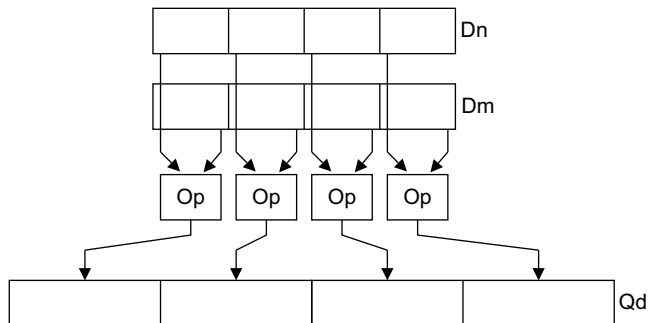

Figure F1-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. [Figure F1-4 on page F1-2392](#) shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.

Figure F1-4 Advanced SIMD instruction producing narrower result

Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the ARM standard floating-point arithmetic defined in *Floating-point and Advanced SIMD support* on page A1-46.

F1.13.1 Advanced SIMD parallel addition and subtraction

Table F1-19 shows the Advanced SIMD parallel add and subtract instructions.

Table F1-19 Advanced SIMD parallel add and subtract instructions

| Instruction | See |
|--|---|
| Vector Add | VADD (integer) on page F6-3289 VADD (floating-point) on page F6-3286 |
| Vector Add and Narrow, returning High Half | VADDHN on page F6-3291 |
| Vector Add Long | VADDL on page F6-3293 |
| Vector Add Wide | VADDW on page F6-3295 |
| Vector Halving Add | VHADD on page F6-3414 |
| Vector Halving Subtract | VHSUB on page F6-3416 |
| Vector Pairwise Add and Accumulate Long | VPADAL on page F6-3562 |
| Vector Pairwise Add | VPADD (integer) on page F6-3566 VPADD (floating-point) on page F6-3564 |
| Vector Pairwise Add Long | VPADDL on page F6-3568 |

| Vector Shift Right | VSHR on page F6-3700 |
| Vector Shift Right and Narrow | VSHRN on page F6-3704 |
| Vector Shift Left and Insert | VSLI on page F6-3708 |
| Vector Shift Right and Accumulate | VSRA on page F6-3712 |
| Vector Shift Right and Insert | VSRI on page F6-3714 |

F1.13.5 Advanced SIMD multiply instructions

Table F1-23 summarizes the Advanced SIMD multiply instructions.

Table F1-23 Advanced SIMD multiply instructions

| Instruction | See |
|--|---|
| Vector Multiply Accumulate | <i>VMLA (integer)</i> on page F6-3484 <i>VMLA (floating-point)</i> on page F6-3481 <i>VMLA (by scalar)</i> on page F6-3486 |
| Vector Multiply Accumulate Long | <i>VMLAL (integer)</i> on page F6-3488 <i>VMLAL (by scalar)</i> on page F6-3490 |
| Vector Multiply Subtract | <i>VMLS (integer)</i> on page F6-3495 <i>VMLS (floating-point)</i> on page F6-3492 <i>VMLS (by scalar)</i> on page F6-3497 |
| Vector Multiply Subtract Long | <i>VMLS (integer)</i> on page F6-3499 <i>VMLS (by scalar)</i> on page F6-3501 |
| Vector Multiply | <i>VMUL (integer and polynomial)</i> on page F6-3533 <i>VMUL (floating-point)</i> on page F6-3530 <i>VMUL (by scalar)</i> on page F6-3535 |
| Vector Multiply Long | <i>VMULL (integer and polynomial)</i> on page F6-3537 <i>VMULL (by scalar)</i> on page F6-3539 |
| Vector Fused Multiply Accumulate | <i>VFMA</i> on page F6-3404 |
| Vector Fused Multiply Subtract | <i>VFMS</i> on page F6-3407 |
| Vector Saturating Doubling Multiply Accumulate Long | <i>VQDMLAL</i> on page F6-3586 |
| Vector Saturating Doubling Multiply Subtract Long | <i>VQDMLSL</i> on page F6-3589 |
| Vector Saturating Doubling Multiply Returning High Half | <i>VQDMULH</i> on page F6-3592 |
| Vector Saturating Rounding Doubling Multiply Returning High Half | <i>VQRDMULH</i> on page F6-3603 |
| Vector Saturating Doubling Multiply Long | <i>VQDMULL</i> on page F6-3595 |

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over {0, 1}. *VMUL* and *VMULL* are the only instructions that operate on polynomials. *VMULL* produces a 16-bit polynomial over {0, 1}.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- Single-precision (32-bit) floating-point numbers.
- Double-precision (64-bit) floating-point numbers.

F1.13.6 Miscellaneous Advanced SIMD data-processing instructions

Table F1-24 shows miscellaneous Advanced SIMD data-processing instructions.

Chapter F2

About the T32 and A32 Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Format of instruction descriptions* on page F2-2402.
- *Standard assembler syntax fields* on page F2-2406.
- *Conditional execution* on page F2-2407.
- *Shifts applied to a register* on page F2-2410.
- *Memory accesses* on page F2-2412.
- *Encoding of lists of general-purpose registers and the PC* on page F2-2413.
- *General information about the T32 and A32 instruction descriptions* on page F2-2414.
- *Additional pseudocode support for instruction descriptions* on page F2-2426.
- *Additional information about Advanced SIMD and floating-point instructions* on page F2-2427.

F2.1 Format of instruction descriptions

The instruction descriptions in [Chapter F5 T32 and A32 Base Instruction Set Instruction Descriptions](#) and [Chapter F6 T32 and A32 Advanced SIMD and floating-point Instruction Descriptions](#) normally use the following format:

- Instruction section title.
- Introduction to the instruction.
- A description of each encoding of the instruction.
- Assembler syntax.
- Pseudocode describing how the instruction operates.
- Notes, if applicable.

Each of these items is described in more detail in the following subsections.

F2.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instruction or instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

F2.1.2 Introduction to the instruction

The introduction to the instruction briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

F2.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- A1, A2, A3 ... for the first, second, third and any additional A32 encodings.
- T1, T2, T3 ... for the first, second, third and any additional T32 encodings.

Each instruction encoding description consists of:

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntax variants are given. These are written in a typewriter font using the conventions described in [Assembler syntax prototype line conventions on page F2-2404](#). The correct one to use can be indicated by:
 - A subheading that identifies the encodings that correspond to the syntax. See, for example, the subheading *Flag setting, rotate right with extend variant* in the description of the A1 encoding of the ADC, ADCS (register) instructions in [A1 on page F5-2563](#).
 - An annotation to the syntax, such as *Inside IT block* or *Outside IT block*. See, for example, the syntax descriptions of the T1 encoding of the ADC, ADCS (register) instructions in [T1 on page F5-2564](#).

In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

There is usually more than one syntax variant that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the T32 instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction then:

- If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see [Standard assembler syntax fields on page F2-2406](#).

- If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings.

Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

———— **Note** —————

In some cases, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the A32 instructions with bits<31:28> == 0b1111 described in [Branch, branch with link, and block data transfer on page F4-2529](#), [System register access, Advanced SIMD, floating-point, and Supervisor Call on page F4-2531](#), and [Unconditional instructions on page F4-2540](#) cannot have a condition code, but the equivalent T32 instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the A32 instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, in order to produce more readable disassembled code.

- An encoding diagram, where:
 - For a 32-bit A32 encoding diagram, the bits are numbered from 31 to 0.
 - For a 16-bit T32 encoding diagram, the bits are numbered from 15 to 0. This halfword can be described as `hw1` of the instruction.
 - For a 32-bit T32 encoding diagram, the bits are numbered from 15 to 0 for each halfword, as a reminder that a 32-bit T32 instruction consists of two consecutive halfwords rather than a word. In this case, the left-hand halfword in the diagram is identified as `hw1`, and the right-hand halfword is identified as `hw2`.

Where instructions are stored using the standard little-endian instruction endianness:

- The encoding diagram for an A32 instruction at address `A` shows, from left to right, the bytes at addresses `A+3`, `A+2`, `A+1`, `A`.
- The encoding diagram for a 32-bit T32 instruction shows bytes in the order `A+1`, `A` for `hw1`, followed by bytes `A+3`, `A+2` for `hw2`.
- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see [Appendix K11 ARM Pseudocode Definition](#).

F2.1.4 Assembler symbols

The *Assembly symbols* describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- Descriptions of all of the variable or optional fields of the syntax.

Some syntax fields are standardized across all or most instructions. [Standard assembler syntax fields on page F2-2406](#) describes these fields.

By default, syntax fields that specify registers, such as <Rd>, <Rn>, or <Rt>, can be any of R0-R12 or LR in T32 instructions, and any of R0-R12, SP or LR in A32 instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as d, n, or t) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

- Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.
- In the case of 16-bit T32 encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if <Rd> and <Rn> specify the same register, and that the register number of that register is encoded in the field if they do.

The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a T32 instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL assembler syntax does not conflict with UAL. ARM recommends that it is supported, as an optional extension to UAL, so that pre-UAL assembler source files can be assembled.

Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

< > Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an instruction contains an item <Rn> and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must only use encodings that produce that output.

{ } Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- Must treat the # as optional where an instruction syntax description shows it as optional.
- Can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note

ARM recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

+/- This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters must be encoded as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

F2.1.5 Pseudocode describing how the instruction operates

The *Operation for all classes* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see [Appendix K11 ARM Pseudocode Definition](#).

F2.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<c> Is an optional field. It specifies the condition under which the instruction is executed. See [Conditional execution on page F2-2407](#) for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<q> Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

.N Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.

.W Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description. The assembler syntax includes a mandatory .W qualifier, along with a note describing the cases in which it applies, where this qualifier is required to select a particular encoding for an instruction. Additional assembler syntax will describe the syntax when the conditions are not met.

———— **Note** —————

When assembling to the A32 instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.

F2.3 Conditional execution

Most T32 and A32 instructions can be executed conditionally, based on the values of the APSR condition flags. Table F2-1 lists the available conditions.

Table F2-1 Condition codes

| cond | Mnemonic extension | Meaning (integer) | Meaning (floating-point) ^a | Condition flags |
|------|------------------------|------------------------------|---------------------------------------|-------------------|
| 0000 | EQ | Equal | Equal | Z == 1 |
| 0001 | NE | Not equal | Not equal, or unordered | Z == 0 |
| 0010 | CS ^b | Carry set | Greater than, equal, or unordered | C == 1 |
| 0011 | CC ^c | Carry clear | Less than | C == 0 |
| 0100 | MI | Minus, negative | Less than | N == 1 |
| 0101 | PL | Plus, positive or zero | Greater than, equal, or unordered | N == 0 |
| 0110 | VS | Overflow | Unordered | V == 1 |
| 0111 | VC | No overflow | Not unordered | V == 0 |
| 1000 | HI | Unsigned higher | Greater than, or unordered | C == 1 and Z == 0 |
| 1001 | LS | Unsigned lower or same | Less than or equal | C == 0 or Z == 1 |
| 1010 | GE | Signed greater than or equal | Greater than or equal | N == V |
| 1011 | LT | Signed less than | Less than, or unordered | N != V |
| 1100 | GT | Signed greater than | Greater than | Z == 0 and N == V |
| 1101 | LE | Signed less than or equal | Less than, equal, or unordered | Z == 1 or N != V |
| 1110 | None (AL) ^d | Always (unconditional) | Always (unconditional) | Any |

- a. Unordered means at least one NaN operand.
- b. HS (unsigned higher or same) is a synonym for CS.
- c. L0 (unsigned lower) is a synonym for CC.
- d. AL is an optional mnemonic extension for always, except in IT instructions. For details see *IT* on page F5-2681.

In T32 instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see *Conditional instructions* on page F1-2369 and *IT* on page F5-2681. Some conditional branch instructions do not require a preceding IT instruction, because they include a condition code in their encoding.

For performance reasons, ARMv8 deprecates the use of IT other than with a single 16-bit T32 instruction from a specified subset of the 16-bit T32 instructions, see *Partial deprecation of IT* on page K5-5531. In addition, implementations can provide a set of ITD control fields, SCTL_R.ITD, SCTL_R.EL1.ITD, and HSCTL_R.ITD, to disable these deprecated uses, making them UNDEFINED. For more information see:

- *Disabling or enabling PL0 and PL1 use of AArch32 deprecated functionality* on page G1-3888.
- *Disabling or enabling EL2 use of AArch32 deprecated functionality* on page G1-3897.

In A32 instructions, bits[31:28] of the instruction contain either:

- The condition code, see *The condition code field in A32 instruction encodings* on page F2-2408.
- 0b1111 for some A32 instructions that can only be executed unconditionally.

ARM deprecates the conditional execution of any instruction encoding provided by Advanced SIMD that is not also provided by floating-point, and strongly recommends that:

- For A32 instructions, any such Advanced SIMD instruction that can be conditionally executed is executed with the <c> field omitted or set to AL.

———— **Note** ————

This applies only to VDUP, see [VDUP \(general-purpose register\) on page F6-3394](#). The other A32 instructions do not permit conditional execution.

- For T32 instructions, such Advanced SIMD instructions are never included in an IT block. This means they must be specified with the <c> field omitted or set to AL.

This deprecation does not apply to Advanced SIMD instruction encodings that are also available as floating-point instruction encodings. That is, it does not apply to the Advanced SIMD encodings of the instructions described in the following sections:

- [VLDM, VLDMDB, VLDMIA on page F6-3458](#).
- [VLDR \(immediate\) on page F6-3463](#) and [VLDR \(literal\) on page F6-3465](#).
- [VMOV \(general-purpose register to scalar\) on page F6-3512](#).
- [VMOV \(between two general-purpose registers and a doubleword floating-point register\) on page F6-3503](#).
- [VMRS on page F6-3525](#).
- [VMSR on page F6-3528](#).
- [VPOP on page F6-3578](#).
- [VPUSH on page F6-3580](#).
- [VSTM, VSTMDB, VSTMIA on page F6-3744](#).
- [VSTR on page F6-3749](#).

See also [Conditional execution of undefined instructions on page G1-3851](#).

F2.3.1 The condition code field in A32 instruction encodings

Every conditional A32 instruction contains a 4-bit condition code field, the cond field, in bits 31 to 28:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| cond | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

This field contains one of the values 0b0000-0b1110, as shown in [Table F2-1 on page F2-2407](#). Most instruction mnemonics can be extended with the letters defined in the [Mnemonic extension on page F2-2407](#) column of that table.

If the *always* (AL) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the AL condition code.

F2.3.2 Pseudocode description of conditional execution

The `AArch32.CurrentCond()` function returns a 4-bit condition specifier as follows:

- For A32 instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see [B on page F5-2607](#)), it returns the 4-bit cond field of the encoding.
- For all other T32 instructions:
 - If `PSTATE.IT<3:0> != '0000'` it returns `PSTATE.IT<7:4>`.
 - If `PSTATE.IT<7:0> == '00000000'` it returns `'1110'`.
 - Otherwise, execution of the instruction is CONstrained UNpredictable.

For more information, see [Process state, PSTATE on page E1-2294](#).

The `ConditionPassed()` function uses this condition specifier and the condition flags to determine whether the instruction must be executed, by calling the `ConditionHolds()` function.

Chapter J1 *ARMv8 Pseudocode* includes the definitions of these functions.

Undefined Instruction exception on page G1-3849 describes the handling of conditional instructions that are UNDEFINED, UNPREDICTABLE, or CONSTRAINED UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see *Limitations of the instruction pseudocode* on page K11-5632.

F2.4 Shifts applied to a register

A32 register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both T32 and A32 data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see *Constant shifts*.

A32 data-processing instructions can apply a register-controlled shift to the second operand register.

F2.4.1 Constant shifts

These are the same in T32 and A32 instructions, except that the input bits come from different positions.

<shift> is an optional shift to be applied to <Rm>. It can be any one of:

| | |
|-----------|--|
| (omitted) | No shift. |
| LSL #<n> | Logical shift left <n> bits. 1 <= <n> <= 31. |
| LSR #<n> | Logical shift right <n> bits. 1 <= <n> <= 32. |
| ASR #<n> | Arithmetic shift right <n> bits. 1 <= <n> <= 32. |
| ROR #<n> | Rotate right <n> bits. 1 <= <n> <= 31. |
| RRX | Rotate right one bit, with extend. Bit[0] is written to shifter_carry_out, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31]. |

Note

Assemblers can permit the use of some or all of ASR #0, LSL #0, LSR #0, and ROR #0 to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of #0 in the immediate forms of ASR, LSL, LSR, and ROR instructions to specify that no shift is to be performed, that is, that a MOV (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for T32 instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the MOV (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes <shift> into two type bits and five immediate bits, as follows:

| | |
|-----------|---|
| (omitted) | type = 0b00, immediate = 0. |
| LSL #<n> | type = 0b00, immediate = <n>. |
| LSR #<n> | type = 0b01. If <n> < 32, immediate = <n>. If <n> == 32, immediate = 0. |
| ASR #<n> | type = 0b10. If <n> < 32, immediate = <n>. If <n> == 32, immediate = 0. |
| ROR #<n> | type = 0b11, immediate = <n>. |
| RRX | type = 0b11, immediate = 0. |

F2.4.2 Register controlled shifts

These are only available in A32 instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

| | |
|-----|---|
| ASR | Arithmetic shift right, encoded as type = 0b10. |
| LSL | Logical shift left, encoded as type = 0b00. |
| LSR | Logical shift right, encoded as type = 0b01. |
| ROR | Rotate right, encoded as type = 0b11. |

The bottom byte of <Rs> contains the shift amount.

F2.4.3 Pseudocode description of instruction-specified shifts and rotates

The pseudocode enumeration [SRTType](#){`}` defines the shift types. Shift and rotate instruction decode is described by the pseudocode function:

- [DecodeImmShift](#)() for a constant shift.
- [DecodeRegShift](#)() for a register controlled shift.

Shift and rotate operations are made by the pseudocode function [Shift](#)().

F2.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

[<Rn>, <offset>]

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

[<Rn>, <offset>]!

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register.

The assembly language syntax for this mode is:

[<Rn>], <offset>

In each case, <Rn> is the base register. <offset> can be:

- An immediate constant, such as <imm8> or <imm12>.
- An index register, <Rm>.
- A shifted index register, such as <Rm>, LSL #<shift>.

For information about unaligned access, endianness, and exclusive access, see:

- [Alignment support on page E2-2323](#).
- [Endian support on page E2-2325](#).
- [Synchronization and semaphores on page E2-2355](#).

F2.6 Encoding of lists of general-purpose registers and the PC

A number of instructions operate on lists of general-purpose registers. For some load instructions, the list of registers to be loaded can include the PC. For these instructions, the assembler syntax includes a <registers> field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit register_list field. This section gives more information about these and other possible register list encodings.

In a register_list field, each bit corresponds to a single register, and if the <registers> field of the assembler instruction includes Rt then register_list<t> is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of general-purpose registers, and possibly the PC, are:

- Except for the cases listed here, 16-bit T32 encodings use an 8-bit register list, and can access only registers R0-R7.

The exceptions to this rule are:

- The T1 encoding of POP uses an 8-bit register list, and an additional bit, P, that corresponds to the PC. This means it can access any of R0-R7 and the PC.
- The T1 encoding of PUSH uses an 8-bit register list, and an additional bit, M, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit T32 encodings of load operations use a 13-bit register list, and two additional bits, M, corresponding to the LR, and P, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit T32 encodings of store operations use a 13-bit register list, and one additional bit, M, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, A32 encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

The exception to this rule is:

- The system instructions LDM (exception return) and LDM (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of POP, and the T3 and A2 encodings of PUSH, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the Rt field.

Note

POP is a load operation, and PUSH is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, registers, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

Note

Some floating-point and Advanced SIMD instructions operate on lists of SIMD and floating-point registers. The assembler syntax of these instructions includes a <list> field that specifies the registers to be operated on, and the description of the instruction in [Alphabetical list of T32 and A32 base instruction set instructions on page F5-2560](#) defines the use and encoding of this field.

F2.7 General information about the T32 and A32 instruction descriptions

Chapter F3 *The T32 Instruction Set Encoding* describes the T32 instruction encodings, and Chapter F4 *The A32 Instruction Set Encoding* describes the A32 instruction encodings. The following subsections give more information about the descriptions of these instructions and their encodings:

- [UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space.](#)
- [T32 and A32 Advanced SIMD and floating-point instruction encodings on page F2-2415.](#)
- [The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions on page F2-2419.](#)
- [The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions on page F2-2420.](#)
- [Modified immediate constants in T32 and A32 instructions on page F2-2420.](#)

F2.7.1 UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE or CONSTRAINED UNPREDICTABLE. ARMv8-A greatly reduces the architecturally UNPREDICTABLE behavior in AArch32 state. Most cases that earlier versions of the architecture describe as UNPREDICTABLE become either:
 - CONSTRAINED UNPREDICTABLE, meaning the architecture defines a limited range of permitted behaviors.
 - Fully predictable.For more information see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in [Chapter F3 The T32 Instruction Set Encoding](#) or [Chapter F4 The A32 Instruction Set Encoding](#).

An instruction is UNPREDICTABLE only if:

- It is declared as UNPREDICTABLE in an instruction description or in [Chapter F3](#) or [Chapter F4](#), and [Appendix K1](#) does not redefine the behavior as CONSTRAINED UNPREDICTABLE.
- The pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively. In most cases, ARMv8 makes these cases CONSTRAINED UNPREDICTABLE, as described in [SBZ or SBO fields T32 and A32 in instructions on page K1-5460](#).

Unless otherwise specified, T32 and A32 instructions provided as part of an architectural extension, or by an optional feature of the architecture, are UNDEFINED in an implementation that does not include that extension or feature.

———— **Note** —————

Examples of where this rule applies are:

- The instructions provided by the Cryptographic Extension.
- The system instructions that provide access to the System registers of the OPTIONAL Performance Monitors Extension.
- The Advanced SIMD and floating-point instructions.

For more information about UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction behavior, see [Undefined Instruction exception on page G1-3849](#).

For more information about the behavior of T32 and A32 instructions in earlier versions of the architecture see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

F2.7.2 T32 and A32 Advanced SIMD and floating-point instruction encodings

The T32 and A32 encodings of Advanced SIMD and floating-point instructions that are described in [Chapter F3 The T32 Instruction Set Encoding](#) and in [Chapter F4 The A32 Instruction Set Encoding](#) are common to the T32 and A32 instruction sets. This means:

- The instruction groups, and the set of instructions in each group, are identical for T32 and A32.
- For each instruction:
 - Each T32 encoding is exactly equivalent to an A32 encoding.
 - There is no T32 encoding without an equivalent A32 encoding, and no A32 encoding without an equivalent T32 encoding.

———— **Note** —————

- In the T32 instruction sets, the Advanced SIMD and floating-point instructions have 32-bit encodings.
- In the base instruction sets, some instructions are common to the T32 and A32 instruction sets, whereas other instructions have equivalent but not identical functionality in the two instruction sets.

32-bit T32 encodings are described as two contiguous halfwords, {hw1:hw2}, as described in [Instruction encodings on page F2-2402](#). In general:

- hw1 of a T32 encoding maps onto bits[31:16] of an equivalent A32 encoding.
- hw2 of a T32 encoding maps onto bits[15:0] of an equivalent A32 encoding.

However, the different structures of the T32 instruction encoding space and the A32 instruction encoding space mean that:

- For a given Advanced SIMD and floating-point instruction group:
 - The positions of the fields that identify the instruction, or instruction encoding, within the instruction group might differ between the T32 encodings and the A32 encodings.
 - However, the field values that identify the instruction of instruction encoding are identical for the T32 encoding and the A32 encoding.

The remainder of this section describes the equivalence of the T32 and A32 encodings for each of the Advanced SIMD and floating-point instruction groups.

Advanced SIMD data-processing

The T32 encoding of the Advanced SIMD data-processing group is:

The A32 encoding of the Advanced SIMD data-processing group is:

The encodings in this group are identified by:

- hw1[15:13] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and:
 - Has the value 0b111 in the T32 encoding.
 - Has the value 0b001 in the A32 encoding.
- hw1[11:8] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value 0b111.

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

| T32 encoding | A32 encoding | Field size |
|--------------|--------------|------------|
| op0:op1 | op0 | 2 bits |
| op2 | op1 | 15 bits |
| op3 | op2 | 1 bit |
| op4 | op3 | 1 bit |

Advanced SIMD element or structure load/store

The T32 encoding of the Advanced SIMD element or structure load/store group is:

The A32 encoding of the Advanced SIMD element or structure load/store group is:

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and has the value 0b1111.
- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and:
 - Has the value 0b1001 in the T32 encoding.
 - Has the value 0b0100 in the A32 encoding.
- hw1[4] of the T32 encoding is equivalent to bit[20] of the A32 encoding, and has the value 0b0.

op0, op1, and op2 are the fields that identify the instructions, or instruction encodings, within this group, and they are in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD load/store and 64-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:

The A32 encoding of the Floating-point and Advanced SIMD load/store and 64-bit register moves group is:

The encodings in the group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - Has the value 0b1110 in the T32 encoding.
 - Can have any value other than 0b1111 in the A32 encoding.
 This range of values is required because A32 instructions in this group can be executed conditionally, see [Conditional execution on page F2-2407](#).
- hw1[11:9] of the T32 encoding is equivalent to bits[27:25] of the A32 encoding, and has the value 0b110.
- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.

op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

Floating-point and Advanced SIMD 32-bit register moves

The T32 encoding of the Floating-point and Advanced SIMD 32-bit register moves group is:

The A32 encoding of the Advanced SIMD 32-bit register moves group is:

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - Has the value 0b1110 in the T32 encoding.
 - Can have any value other than 0b1111 in the A32 encoding.
 This range of values is required because A32 instructions in this group can be executed conditionally, see [Conditional execution on page F2-2407](#).
- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.

- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.
 - hw2[4:0] of the T32 encoding is equivalent to bits[4:0] of the A32 encoding, and has the value 0b11111.
- op0 is the field that identifies the instructions, or instruction encodings, within this group, and is in equivalent positions in the T32 and A32 encodings.

Floating-point data-processing

The T32 encoding of the Floating-point data-processing group is:

The A32 encoding of the Floating-point data-processing group is:

The encodings in this group are identified by:

- hw1[15:12] of the T32 encoding is equivalent to bits[31:28] of the A32 encoding, and:
 - In the T32 encoding, hw1[15:13] has the value 0b111, and hw1[12] is the op0 parameter used in identifying instruction encodings within this group.
 - In the A32 encoding, is the cond field and also implies the value of bit[28] of some A32 instruction encodings within this group, as the following table shows:

| cond | Significance of bit[28] in A32 encodings |
|-----------|--|
| != 0b1111 | Part of the cond field. |
| 0b1111 | Has fixed value of 1. |

The range of cond values other than 0b1111 is required because A32 instructions in this group can be executed conditionally, see [Conditional execution on page F2-2407](#).

- hw1[11:8] of the T32 encoding is equivalent to bits[27:24] of the A32 encoding, and has the value 0b1110.
- hw2[11:9] of the T32 encoding is equivalent to bits[11:9] of the A32 encoding, and has the value 0b101.
- hw2[4] of the T32 encoding is equivalent to bit[4] of the A32 encoding, and has the value 0b0.

This table shows the equivalence of the fields that identify the instructions, or instruction encodings, within this group:

| T32 encoding | A32 encoding |
|--------------|---|
| op0 | Bit[28] of the instruction encoding is 1 when cond is 0b1111. |
| op1 | op0 |
| op2 | op1 |
| op3 | op2 |

F2.7.3 The PC and the use of 0b1111 as a register specifier in T32 and A32 instructions

Restrictions on the use of PC or 0b1111 as a register specifier differ between the T32 and the A32 instruction sets, as described in:

- [T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier.](#)
- [A32 restrictions on the use of PC or 0b1111 as a register specifier on page F2-2420.](#)

T32 restrictions on the use of the PC, and use of 0b1111 as a register specifier

The use of 0b1111 as a register specifier is not normally permitted in T32 instructions. When a value of 0b1111 is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions TBB and TBH can be the PC. This means branch tables can be placed in memory immediately after the instruction.

———— **Note** —————

ARM deprecates use of the PC as the base register in the STC instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute A32 or T32 instructions after the branch.
- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
 - Implicitly, for example, branch instructions.
 - Explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions.
 - Explicitly by using a register mask, for example LDM instructions.

The address to branch to can be:

- A loaded value, for example, RFE.
- A register value, for example, BX.
- The result of a calculation, for example, TBB or TBH.

The method of choosing the instruction set used after the branch can be:

- Similar to the LDR case, for example, LDM or BX.
 - A fixed instruction set other than the one currently being used, for example, the immediate form of BLX.
 - Unchanged, for example, branch instructions or 16-bit MOV (register) instructions.
 - Set from the [SPSR.T](#) bit, for RFE and SUBS PC, LR, #imm8.
- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.
 - If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.
 - If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the System register are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.

A32 restrictions on the use of PC or 0b1111 as a register specifier

In A32 instructions, the use of 0b1111 as a register specifier specifies the PC.

Many instructions are CONstrained UNPREDICTABLE if they use 0b1111 as a register specifier. This is specified by pseudocode in the instruction description. ARMv8-A constrains the resulting CONstrained UNPREDICTABLE behavior, see [Using R15 on page K1-5457](#).

———— **Note** —————

ARM deprecates use of the PC as the base register in any store instruction.

F2.7.4 The SP and the use of 0b1101 as a register specifier in T32 and A32 instructions

In the T32 and A32 instruction sets, ARM recommends that the use of 0b1101 as a register specifier specifies the SP.

———— **Note** —————

- The recommendation that the register specifier 0b1101 is only used to specify the SP applies to both the T32 and the A32 instruction sets.
 - Despite this recommendation, T32 instructions that can access R13, or the SP, behave predictably in ARMv8. This differs from ARMv7, where many uses of R13 are defined as UNPREDICTABLE. For more information about these cases see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.
-

F2.7.5 Modified immediate constants in T32 and A32 instructions

The following sections describe the encoding of modified immediate constants:

- [Modified immediate constants in T32 instructions](#).
- [Modified immediate constants in A32 instructions on page F2-2422](#).
- [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2423](#).
- [Modified immediate constants in T32 and A32 floating-point instructions on page F2-2424](#).

Modified immediate constants in T32 instructions

The encoding of a modified immediate constant in a 32-bit T32 instruction is:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|------|----|----|-----------------|----|----|---|---|---|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | | | | | | | | | imm3 | | | a b c d e f g h | | | | | | | | | | | | |

Table F2-2 shows the range of modified immediate constants available in T32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table F2-2 Encoding of modified immediates in T32 data-processing instructions

| i:imm3:a | <const> ^a |
|----------|--|
| 0000x | 00000000 00000000 00000000 abcdefgh |
| 0001x | 00000000 abcdefgh 00000000 abcdefgh ^b |
| 0010x | abcdefgh 00000000 abcdefgh 00000000 ^b |
| 0011x | abcdefgh abcdefgh abcdefgh abcdefgh ^b |
| 01000 | 1bcdefgh 00000000 00000000 00000000 |
| 01001 | 01bcdefg h0000000 00000000 00000000 ^c |
| 01010 | 001bcdef gh000000 00000000 00000000 |
| 01011 | 0001bcde fgh00000 00000000 00000000 ^c |
| . | . |
| . | . 8-bit values shifted to other positions |
| . | . |
| 11101 | 00000000 00000000 000001bc defgh000 ^c |
| 11110 | 00000000 00000000 0000001b cdefgh00 |
| 11111 | 00000000 00000000 00000001 bcdefgh0 ^c |

- a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).
- b. ARM deprecates using a modified immediate with abcdefgh == 00000000, and these cases are CONSTRAINED UNPREDICTABLE, see *UNPREDICTABLE cases in immediate constants in T32 data-processing instructions* on page K1-5460.
- c. Not available in A32 instructions if h == 1.

Note

As the footnotes to Table F2-2 show, the range of values available in T32 modified immediate constants is slightly different from the range of values available in A32 instructions. See *Modified immediate constants in A32 instructions* on page F2-2422 for the A32 values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, T32 instructions

For a T32 data-processing instruction, the `T32ExpandImm()` pseudocode function returns the value of the 32-bit immediate constant, calling `T32ExpandImm_C()` to evaluate the constant.

Modified immediate constants in A32 instructions

The encoding of a modified immediate constant in an A32 instruction is:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | | | | | | | rotation | | a | b | c | d | e | f | g | h | | | | | | | | |

Table F2-3 shows the range of modified immediate constants available in A32 data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table F2-3 Encoding of modified immediates in A32 processing instructions

| rotation | <const> ^a |
|----------|---|
| 0000 | 00000000 00000000 00000000 abcdefgh |
| 0001 | gh000000 00000000 00000000 00abcdef |
| 0010 | efgh0000 00000000 00000000 0000abcd |
| 0011 | cdefgh00 00000000 00000000 000000ab |
| 0100 | abcdefgh 00000000 00000000 00000000 |
| . | . |
| . | . 8-bit values shifted to other even-numbered positions |
| . | . |
| 1001 | 00000000 00abcdef gh000000 00000000 |
| . | . |
| . | . 8-bit values shifted to other even-numbered positions |
| . | . |
| 1110 | 00000000 00000000 0000abcd efgh0000 |
| 1111 | 00000000 00000000 000000ab cdefgh00 |

a. This table shows the immediate constant value in binary form, to relate abcdefgh to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Note

The range of values available in A32 modified immediate constants is slightly different from the range of values available in 32-bit T32 instructions. See *Modified immediate constants in T32 instructions* on page F2-2420.

Carry out

A logical instruction with the rotation field set to 0b0000 does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table F2-3. For example, the constant #3 must be encoded with (rotation, abcdefgh) == (0b0000, 0b00000011), not (0b0001, 0b00001100), (0b0010, 0b00110000), or (0b0011, 0b11000000).

In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of T32 modified immediate constants for all constants that are permitted in both the A32 and T32 instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

- <byte> Is the numeric value of abcdefgh, in the range 0-255.
- <rot> Is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all A32 data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the T32 instruction set, and ARM deprecates their use.

Operation of modified immediate constants, A32 instructions

For an A32 data-processing instruction, the `A32ExpandImm()` pseudocode function returns the value of the 32-bit immediate constant, calling `A32ExpandImm_C()` to evaluate the constant.

Modified immediate constants in T32 and A32 Advanced SIMD instructions

Table F2-4 shows the modified immediate constants available with Advanced SIMD instructions, and how they are encoded.

Table F2-4 Modified immediate values for Advanced SIMD instructions

| op | cmode | Constant ^a | <dt> ^b | Notes |
|----|-------|---|-------------------|-------|
| - | 000x | 00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh | I32 | c |
| | 001x | 00000000 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 | I32 | c, d |
| | 010x | 00000000 abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000 | I32 | c, d |
| | 011x | abcdefgh 00000000 00000000 00000000 abcdefgh 00000000 00000000 00000000 | I32 | c, d |
| | 100x | 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh | I16 | c |
| | 101x | abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 abcdefgh 00000000 | I16 | c, d |
| | 1100 | 00000000 00000000 abcdefgh 11111111 00000000 00000000 abcdefgh 11111111 | I32 | d, e |
| | 1101 | 00000000 abcdefgh 11111111 11111111 00000000 abcdefgh 11111111 11111111 | I32 | d, e |
| 0 | 1110 | abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh | I8 | f |
| | 1111 | aBbbbbc defgh000 00000000 00000000 aBbbbbc defgh000 00000000 00000000 | F32 | f, g |
| 1 | 1110 | aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh | I64 | f |
| | 1111 | UNDEFINED | - | - |

- a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of I32 and a value of 10 specify the 64-bit constant 0x0000000A0000000A.
- b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, VMOV.I64 D0, #0x8000000080000000 does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as VMOV.I32 D0, #0x80000000.
- c. This constant is available for the VBIC, VMOV, VMVN, and VORR instructions.

- d. CONSTRAINED UNPREDICTABLE if abcdefgh == 0b00000000, see *UNPREDICTABLE cases in immediate constants in Advanced SIMD instructions on page K1-5461*. The required behavior is that these encodings produce an immediate constant of zero.
- e. This constant is available for the VMOV and VMN instructions only.
- f. This constant is available for the VMOV instruction only.
- g. In this entry, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$, where $S = \text{UInt}(a)$, $\text{exp} = \text{UInt}(\text{NOT}(b):c:d)-3$ and $\text{mantissa} = (16+\text{UInt}(e:f:g:h))/16$.

Operation of modified immediate constants, Advanced SIMD instructions

For a T32 or A32 Advanced SIMD instruction that uses a modified immediate constant, the operation described by the AdvSIMDEExpandImm() pseudocode function returns the value of the 64-bit immediate constant.

Modified immediate constants in T32 and A32 floating-point instructions

Table F2-5 shows the immediate constants available in the VMOV (immediate) floating-point instruction, and Table F2-6 shows the resulting floating-point values.

Table F2-5 Floating-point modified immediate constants

| Data type | imm4H | imm4L | Constant ^a |
|-----------|-------|-------|---|
| F32 | abcd | efgh | aBbbbbbc defgh000 00000000 00000000 |
| F64 | abcd | efgh | aBbbbbbb bbcdefgh 00000000 00000000 00000000 00000000 00000000 00000000 |

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{\text{exp}} \times \text{mantissa}$, where $S = \text{UInt}(a)$, $\text{exp} = \text{UInt}(\text{NOT}(b):c:d)-3$ and $\text{mantissa} = (16+\text{UInt}(e:f:g:h))/16$.

Table F2-6 Floating-point constant values

Operation of modified immediate constants, floating-point instructions

For a T32 or A32 floating-point instruction that uses a modified immediate constant, the operation described by the [VFPEExpandImm\(\)](#) pseudocode function returns the value of the immediate constant.

F2.8 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of A32 and T32 instructions, see:

- [Pseudocode description of conditional execution on page F2-2408](#).
- [Pseudocode description of instruction-specified shifts and rotates on page F2-2411](#)

The following subsection gives additional pseudocode support functions for some of the instructions described in [Alphabetical list of T32 and A32 base instruction set instructions on page F5-2560](#). See also [Pseudocode support for the Banked register transfer instructions on page F5-3231](#).

F2.8.1 Pseudocode description of operations for System register access instructions

The `AArch32.CheckSystemAccess()` pseudocode function determines whether a System register access instruction is accepted for execution.

The `AArch32.SysRegRead()` function obtains the word for an MRC instruction from the System register.

The `AArch32.SysRegRead64()` function obtains the two words for an MRRC instruction from the System register.

———— **Note** —————

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The `AArch32.SysRegWrite()` procedure sends the word for an MCR instruction to the System register.

The `AArch32.SysRegWrite64()` procedure sends the two words for an MCRR instruction to the System register.

———— **Note** —————

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

The `CP14DebugInstrDecode()` pseudocode function decodes an accepted access to a debug System register in the (coproc==0b1110) encoding space.

The `CP14JazelleInstrDecode()` pseudocode function decodes an accepted access to a Jazelle System register. These registers are in the (coproc==0b1110) encoding space.

The `CP14TraceInstrDecode()` pseudocode function decodes an accepted access to a Trace System register. These registers are in the (coproc==0b1110) encoding space.

The `CP15InstrDecode()` pseudocode function decodes an accepted access to a System register in the (coproc==0b1111) encoding space.

F2.8.2 Pseudocode details of system calls

The `AArch32.CallSupervisor()` pseudocode function generates a Supervisor Call exception. Valid execution of the SVC instruction calls this function.

The `AArch32.CallHypervisor()` pseudocode function generates an HVC exception. Valid execution of the HVC instruction calls this function.

F2.9 Additional information about Advanced SIMD and floating-point instructions

The following subsections give additional information about the Advanced SIMD and floating-point instructions:

- [Advanced SIMD and floating-point instruction syntax](#).
- [The Advanced SIMD addressing mode](#).
- [Advanced SIMD instruction modifiers](#) on page F2-2428.
- [Advanced SIMD operand shapes](#) on page F2-2428.
- [Data type specifiers](#) on page F2-2429.
- [Register specifiers](#) on page F2-2430.
- [Register lists](#) on page F2-2431.
- [Register encoding](#) on page F2-2431.
- [Advanced SIMD scalars](#) on page F2-2432.

Note

The Advanced SIMD architecture, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.

F2.9.1 Advanced SIMD and floating-point instruction syntax

Advanced SIMD and floating-point instructions use the general conventions of the T32 and A32 instruction sets.

Advanced SIMD and floating-point data-processing instructions use the following general format:

$V\{\langle\text{modifier}\rangle\}\langle\text{operation}\rangle\{\langle\text{shape}\rangle\}\{\langle\text{c}\rangle\}\{\langle\text{q}\rangle\}\{.\langle\text{dt}\rangle\} \{\langle\text{dest}\rangle,\} \langle\text{src1}\rangle, \langle\text{src2}\rangle$

All Advanced SIMD and floating-point instructions begin with a *v*. This distinguishes Advanced SIMD vector and floating-point instructions from scalar instructions.

The main operation is specified in the $\langle\text{operation}\rangle$ field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The $\langle\text{c}\rangle$ and $\langle\text{q}\rangle$ fields are standard assembler syntax fields. For details see [Standard assembler syntax fields](#) on page F2-2406.

F2.9.2 The Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

$[\langle\text{Rn}\rangle\{:\langle\text{align}\rangle\}]$ The address is contained in general-purpose register *Rn*.

Rn is not updated by this instruction.

Encoded as $Rm = 0b1111$.

If *Rn* is encoded as $0b1111$, the instruction is CONstrained UNpredictable.

$[\langle\text{Rn}\rangle\{:\langle\text{align}\rangle\}]!$ The address is contained in general-purpose register *Rn*.

Rn is updated by this instruction: $Rn = Rn + \text{transfer_size}$

Encoded as $Rm = 0b1101$.

transfer_size is the number of bytes transferred by the instruction. This means that, after the instruction is executed, *Rn* points to the address in memory immediately following the last address loaded from or stored to.

If *Rn* is encoded as $0b1111$, the instruction is CONstrained UNpredictable.

This addressing mode can also be written as:

$[\langle\text{Rn}\rangle\{:\langle\text{align}\rangle\}], \#\langle\text{transfer_size}\rangle$

However, disassembly produces the $[\langle\text{Rn}\rangle\{:\langle\text{align}\rangle\}]!$ form.

[<Rn>{:<align>}], <Rm>

The address is contained in general-purpose register <Rn>.

Rn is updated by this instruction: $Rn = Rn + Rm$

Encoded as $Rm = Rm$. Rm must not be encoded as 0b1111 or 0b1101, the PC or the SP.

If Rn is encoded as 0b1111, the instruction is CONSTRAINED UNPREDICTABLE.

The CONSTRAINED UNPREDICTABLE behavior of encodings where Rn is 0b1111 is that the instruction is either UNDEFINED or executes as a NOP, see [CONSTRAINED UNPREDICTABLE behavior for A32 memory hints, Advanced SIMD instructions, and miscellaneous instructions on page K1-5467](#).

In all cases, <align> specifies an alignment, as specified by the individual instruction descriptions.

Previous versions of the manual used the @ character for alignment. So, for example, the first format in this section was shown as [<Rn>{@<align>}]. Both @ and : are supported. However, to ensure portability of code to assemblers that treat @ as a comment character, : is preferred.

F2.9.3 Advanced SIMD instruction modifiers

The <modifier> field provides additional variants of some instructions. [Table F2-7](#) provides definitions of the modifiers. Modifiers are not available for every instruction.

Table F2-7 Advanced SIMD instruction modifiers

| <modifier> | Meaning |
|------------|---|
| Q | The operation uses saturating arithmetic. |
| R | The operation performs rounding. |
| D | The operation doubles the result (before accumulation, if any). |
| H | The operation halves the result. |

F2.9.4 Advanced SIMD operand shapes

The <shape> field provides additional variants of some instructions. [Table F2-8](#) provides definitions of the shapes. Operand shapes are not available for every instruction.

Table F2-8 Advanced SIMD operand shapes

| <shape> | Meaning | Typical register shape |
|---------|---|--------------------------|
| (none) | The operands and result are all the same width. | Dd, Dn, Dm Qd, Qn, Qm |
| L | Long operation - result is twice the width of both operands | Qd, Dn, Dm |
| N | Narrow operation - result is half the width of both operands | Dd, Qn, Qm |
| W | Wide operation - result and first operand are twice the width of the second operand | Qd, Qn, Dm |

Note

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32 q0, q1, q2`. This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in [Table F2-8](#).

F2.9.5 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- The second operand, if any.
- The operand, if there is no second operand.
- The result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see [Data types supported by the Advanced SIMD implementation on page E1-2302](#).

In the instruction syntax descriptions in [Chapter F2 About the T32 and A32 Instruction Descriptions](#), the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:
`VSUBW.I16.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`
- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:
`VSUBW.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`
- Software can specify two data types, specifying the data types of the single operand and the result. For example:
`VMOVN.I16.I32 D0, Q1` instead of `VMOVN.I32 D0, Q1`
- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in [Table F2-9](#).
- Where an instruction does not require a data type, software can provide one.
- The F32 data type can be abbreviated to F.
- The F64 data type can be abbreviated to D.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table F2-9 Data type specification flexibility

| Specified data type | Permitted more specific data types | | | | |
|---------------------|------------------------------------|----------|----------|------|------------|
| None | Any | | | | |
| .I<size> | - | .S<size> | .U<size> | - | - |
| .8 | .I8 | .S8 | .U8 | .P8 | - |
| .16 | .I16 | .S16 | .U16 | .P16 | .F16 |
| .32 | .I32 | .S32 | .U32 | - | .F32 or .F |
| .64 | .I64 | .S64 | .U64 | - | .F64 or .D |

F2.9.6 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table F2-10 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table F2-10 Advanced SIMD and floating-point register specifier formats

| <specifier> | Usual meaning ^a | Used in |
|--------------------------|---|-------------------|
| <Qd> | A quadword destination register for the result vector. | Advanced SIMD |
| <Qn> | A quadword source register for the first operand vector. | Advanced SIMD |
| <Qm> | A quadword source register for the second operand vector. | Advanced SIMD |
| <Dd> | A doubleword destination register for the result vector. | Both |
| <Dn> | A doubleword source register for the first operand vector. | Both |
| <Dm> | A doubleword source register for the second operand vector. | Both |
| <Sd> | A singleword destination register for the result vector. | Floating-point |
| <Sn> | A singleword source register for the first operand vector. | Floating-point |
| <Sm> | A singleword source register for the second operand vector. | Floating-point |
| <Dd[x]> | A destination scalar for the result. Element x of vector <Dd>. | Advanced SIMD |
| <Dn[x]> | A source scalar for the first operand. Element x of vector <Dn>. | Both ^b |
| <Dm[x]> | A source scalar for the second operand. Element x of vector <Dm>. | Advanced SIMD |
| <Rt> | A general-purpose register, used for a source or destination address. | Both |
| <Rt2> | A general-purpose register, used for a source or destination address. | Both |
| <Rn> | A general-purpose register, used as a load or store base address. | Both |
| <Rm> | A general-purpose register, used as a post-indexed address source. | Both |

- a. In some instructions the roles of registers are different.
- b. In the floating-point instructions, <Dn[x]> is used only in VMOV (scalar to general-purpose register), see [VMOV \(scalar to general-purpose register\)](#) on page F6-3516.

F2.9.7 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table F2-11 shows some register list formats, with examples of actual register lists corresponding to those formats.

———— **Note** ————

Register lists must not wrap around the end of the register bank.

Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example {D0-D3} instead of {D0, D1, D2, D3}.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example {Q1, Q2} instead of {D2-D5}.
- Where a register list contains only one register, the enclosing braces can be omitted, for example VLD1.8 D0, [R0] instead of VLD1.8 {D0}, [R0].

Table F2-11 Example register lists

| Format | Example | Alternative |
|------------------------|----------------|-------------|
| {<Dd>} | {D3} | D3 |
| {<Dd>, <Dd+1>, <Dd+2>} | {D3, D4, D5} | {D3-D5} |
| {<Dd[x]>, <Dd+2[x]>} | {D0[3], D2[3]} | - |
| {<Dd[]>} | {D7[]} | D7[] |

F2.9.8 Register encoding

An Advanced SIMD register is either:

- *Quadword*, meaning it is 128 bits wide.
- *Doubleword*, meaning it is 64 bits wide.

Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A floating-point register is either:

- *Double-precision*, meaning it is 64 bits wide.
- *Single-precision*, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The T32 instruction encoding of Advanced SIMD or floating-point registers is:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|----|---|---|---|---|----|----|----|----|----|----|---|---|---|----|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | | | D | Vn | | | | | Vd | | | | | sz | N | Q | M | Vm | | | | | | |

The A32 instruction encoding of Advanced SIMD or floating-point registers is:

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|----|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | | | D | Vn | | | | | Vd | | | | | sz | N | Q | M | Vm | | | | | | |

Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table F2-12 shows the encodings for the registers.

Table F2-12 Encoding of register numbers

| Register mnemonic | Usual usage | Register number encoded in ^a | Notes ^a | Used in |
|-------------------|-----------------------------------|---|---------------------------|----------------|
| <Qd> | Destination (quadword) | D, Vd (bits[22, 15:13]) | bit[12] == 0 ^b | Advanced SIMD |
| <Qn> | First operand (quadword) | N, Vn (bits[7, 19:17]) | bit[16] == 0 ^b | Advanced SIMD |
| <Qm> | Second operand (quadword) | M, Vm (bits[5, 3:1]) | bit[0] == 0 ^b | Advanced SIMD |
| <Dd> | Destination (doubleword) | D, Vd (bits[22, 15:12]) | - | Both |
| <Dn> | First operand (doubleword) | N, Vn (bits[7, 19:16]) | - | Both |
| <Dm> | Second operand (doubleword) | M, Vm (bits[5, 3:0]) | - | Both |
| <Sd> | Destination (single-precision) | Vd, D (bits[15:12, 22]) | - | Floating-point |
| <Sn> | First operand (single-precision) | Vn, N (bits[19:16, 7]) | - | Floating-point |
| <Sm> | Second operand (single-precision) | Vm, M (bits[3:0, 5]) | - | Floating-point |

- a. Bit numbers given for the A32 instruction encoding. See the figures in this section for the equivalent bits in the T32 encoding.
- b. If this bit is 1, the instruction is UNDEFINED.

F2.9.9 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table F2-13 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, $D_m[x]$ in a 32-bit context ($0 \leq m \leq 15$, $0 \leq x \leq 1$) is equivalent to $S[2m + x]$.

Table F2-13 Encoding of scalars in multiply instructions

| Scalar mnemonic | Usual usage | Scalar size | Register specifier | Index specifier | Accessible registers |
|----------------------|----------------|-------------|--------------------|-----------------|----------------------|
| <D _m [x]> | Second operand | 16-bit | Vm[2:0] | M, Vm[3] | D0-D7 |
| | | 32-bit | Vm[3:0] | M | D0-D15 |

Chapter F3

The T32 Instruction Set Encoding

This chapter introduces the T32 instruction set and describes how it uses the ARM programmers' model. It contains the following sections:

- [Top level T32 instruction set encoding on page F3-2434.](#)
- [16-bit T32 instruction encoding on page F3-2436.](#)
- [32-bit T32 instruction encoding on page F3-2447.](#)

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

F3.1 Top level T32 instruction set encoding

The T32 instruction stream is treated as a sequence of halfword-aligned halfwords. Each T32 instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

When the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- 0b11101.
- 0b11110.
- 0b11111.

Otherwise, the halfword is a 16-bit instruction.

Table F3-1 Main encoding table for the T32 instruction set

| Decode fields | | Decode group or instruction page |
|---------------|-------|---|
| op0 | op1 | |
| != 111 | - | 16-bit T32 instruction encoding on page F3-2436 |
| 111 | 00 | B - T2 variant |
| 111 | != 00 | 32-bit T32 instruction encoding on page F3-2447 |

The behavior of an attempt to execute an unallocated instruction is described in [UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space on page F2-2414](#).

F3.1.1 About the T32 Advanced SIMD and floating-point instructions and their encoding

The Advanced SIMD and floating-point instructions are common to the T32 and A32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

All T32 Advanced SIMD and floating-point instructions have 32-bit encodings. Different groups of these instructions are decoded from different points in the 32-bit T32 instruction decode structure. [Table F3-2](#) shows these instruction groups, and where each group is decoded from the overall T32 decode structure:

Table F3-2 Advanced SIMD and floating-point instructions in the T32 decode structure

| Advanced SIMD and floating-point instruction group | T32 decode is from |
|--|--|
| Advanced SIMD data-processing on page F3-2454 | System register access, Advanced SIMD, and floating-point instructions on page F3-2447 |
| Floating-point data-processing on page F3-2450 | System register access, Advanced SIMD, and floating-point instructions on page F3-2447 |

| 1111 | - | - | - | - | - | Unallocated |

System register 32-bit move

This section describes the encoding of the System register 32-bit move instruction class. This section is decoded from [System register access on page F3-2464](#).

Decode fields

| Decode fields | | Instruction Page |
|---------------|---|---------------------|
| o0 | L | |
| 0 | 0 | MCR |
| 0 | 1 | MRC |
| 1 | x | Unallocated |

F3.3.2 Load/Store multiple

This section describes the encoding of the Load/Store multiple instruction class. This section is decoded from *32-bit T32 instruction encoding* on page F3-2447.

| Decode fields | | Instruction Page |
|---------------|---|--|
| opc | L | |
| 00 | 0 | SRS, SRSDA, SRSDB, SRSIA, SRSIB - T1 variant |
| 00 | 1 | RFE, RFEDA, RFEDB, RFEIA, RFEIB - T1 variant |
| 01 | 0 | STM, STMIA, STMEA |
| 01 | 1 | LDM, LDMIA, LDMFD |
| 10 | 0 | STMDB, STMFD |
| 10 | 1 | LDMDB, LDMEA |
| 11 | 0 | SRS, SRSDA, SRSDB, SRSIA, SRSIB - T2 variant |
| 11 | 1 | RFE, RFEDA, RFEDB, RFEIA, RFEIB - T2 variant |

F3.3.3 Load/Store dual, Load/Store Exclusive, Load-Acquire/Store-Release, and table branch

This section describes the encoding of the Load/Store dual, Load/Store Exclusive, Load-Acquire/Store-Release, and table branch group. This section is decoded from *32-bit T32 instruction encoding* on page F3-2447.

| Decode fields | | | | Decode group or instruction page |
|---------------|-----|---------|-----|---|
| op0 | op1 | op2 | op3 | |
| 0010 | - | - | - | Load/Store Exclusive word on page F3-2467 |
| 0110 | 0 | - | 000 | Unallocated. |
| 0110 | 1 | - | 000 | TBB, TBH |
| 0110 | - | - | 01x | Load/Store Exclusive byte/half/dual on page F3-2467 |
| 0110 | - | - | 1xx | Load-Acquire/Store-Release on page F3-2468 |
| 0x11 | - | != 1111 | - | Load/Store dual (immediate, post-indexed) on page F3-2469 |

| Decode fields | | | | Decode group or instruction page |
|---------------|-----|---------|-----|--|
| op0 | op1 | op2 | op3 | |
| 1x10 | - | != 1111 | - | Load/Store dual (immediate) on page F3-2469 |
| 1x11 | - | != 1111 | - | Load/Store dual (immediate, pre-indexed) on page F3-2469 |
| != 0xx0 | - | 1111 | - | LDRD (literal) |

Load/Store Exclusive word

This section describes the encoding of the Load/Store Exclusive word instruction class. This section is decoded from [Load/Store dual](#), [Load/Store Exclusive](#), [Load-Acquire/Store-Release](#), and [table branch](#) on page F3-2466.

| | | | | | | | | | | | | | | | | | | | |

| 0 | 10 | 0 | - | STR (immediate) |
| 0 | 10 | 1 | - | LDR (immediate) |
| 0 | 11 | - | - | Unallocated. |
| 1 | 00 | 1 | - | LDRSB (immediate) |
| 1 | 00 | 1 | 1111 | PLI (immediate, literal) |
| 1 | 01 | 1 | !=1111 | LDRSH (immediate) |
| 1 | 01 | 1 | 1111 | Reserved hint, behaves as NOP. |
| 1 | 1x | 1 | - | Unallocated. |

Load/Store (unprivileged)

This section describes the encoding of the Load/Store (unprivileged) instruction class. This section is decoded from *Load/Store single* on page F3-2485.

| Decode fields | | | Instruction Page |
|---------------|------|---|------------------|
| S | size | L | |
| 0 | 00 | 0 | STRBT |
| 0 | 00 | 1 | LDRBT |
| 0 | 01 | 0 | STRHT |

| Decode fields | | | Instruction Page |
|---------------|------|---|------------------|
| S | size | L | |
| 0 | 01 | 1 | LDRHT |
| 0 | 10 | 0 | STRT |
| 0 | 10 | 1 | LDRT |
| 0 | 11 | - | Unallocated. |
| 1 | 00 | 1 | LDRSBT |
| 1 | 01 | 1 | LDRSHT |
| 1 | 1x | 1 | Unallocated. |

Load/Store (immediate, pre-indexed)

This section describes the encoding of the Load/Store (immediate, pre-indexed) instruction class. This section is decoded from *Load/Store single* on page F3-2485.

| Decode fields | | | Instruction Page |
|---------------|------|---|-------------------|
| S | size | L | |
| 0 | 00 | 0 | STRB (immediate) |
| 0 | 00 | 1 | LDRB (immediate) |
| 0 | 01 | 0 | STRH (immediate) |
| 0 | 01 | 1 | LDRH (immediate) |
| 0 | 10 | 0 | STR (immediate) |
| 0 | 10 | 1 | LDR (immediate) |
| 0 | 11 | - | Unallocated. |
| 1 | 00 | 1 | LDRSB (immediate) |
| 1 | 01 | 1 | LDRSH (immediate) |
| 1 | 1x | 1 | Unallocated. |

Load/Store (positive immediate)

This section describes the encoding of the Load/Store (positive immediate) instruction class. This section is decoded from [Load/Store single](#) on page F3-2485.

| Decode fields | | | | Instruction Page |
|---------------|------|---|---------|---|
| S | size | L | Rt | |
| 0 | 00 | 0 | - | STRB (immediate) |
| 0 | 00 | 1 | != 1111 | LDRB (immediate) |
| 0 | 00 | 1 | 1111 | PLD, PLDW (immediate) - Preload read variant |
| 0 | 01 | 0 | - | STRH (immediate) |
| 0 | 01 | 1 | != 1111 | LDRH (immediate) |
| 0 | 01 | 1 | 1111 | PLD, PLDW (immediate) - Preload write variant |
| 0 | 10 | 0 | - | STR (immediate) |
| 0 | 10 | 1 | - | LDR (immediate) |
| 1 | 00 | 1 | != 1111 | LDRSB (immediate) |
| 1 | 00 | 1 | 1111 | PLI (immediate, literal) |
| 1 | 01 | 1 | != 1111 | LDRSH (immediate) |
| 1 | 01 | 1 | 1111 | Reserved hint, behaves as NOP . |

Load literal

This section describes the encoding of the Load literal instruction class. This section is decoded from [Load/Store single](#) on page F3-2485.

| Decode fields | | | | Instruction Page |
|---------------|------|---|---------|--------------------------------|
| S | size | L | Rt | |
| 0 | 0x | 1 | 1111 | PLD (literal) |
| 0 | 00 | 1 | != 1111 | LDRB (literal) |
| 0 | 01 | 1 | != 1111 | LDRH (literal) |
| 0 | 10 | 1 | - | LDR (literal) |
| 0 | 11 | - | - | Unallocated. |

| Decode fields | | | | Instruction Page |
|---------------|------|---|---------|--------------------------------|
| S | size | L | Rt | |
| 1 | 00 | 1 | != 1111 | LDRSB (literal) |

Chapter F4

The A32 Instruction Set Encoding

This chapter describes the encoding of the A32 instruction set. It contains the following sections:

- *Top level A32 instruction set encoding* on page F4-2500.
- *Data-processing and miscellaneous instructions* on page F4-2502.
- *Load/Store Word, Unsigned byte (immediate, literal)* on page F4-2519.
- *Load/Store Word, Unsigned byte (register)* on page F4-2520.
- *Media instructions* on page F4-2521.
- *Branch, branch with link, and block data transfer* on page F4-2529.
- *System register access, Advanced SIMD, floating-point, and Supervisor Call* on page F4-2531.
- *Unconditional instructions* on page F4-2540.

In this chapter:

- In the decode tables, an entry of - for a field value means the value of the field does not affect the decoding.
- In the decode diagrams, a shaded field indicates that the bits in that field are not used in that level of decode.

F4.1 Top level A32 instruction set encoding

The A32 instruction stream is a sequence of word-aligned words. Each A32 instruction is a single 32-bit word in that stream. The encoding of an A32 instruction is:

Most A32 instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the cond field. For more information, see [The condition code field in A32 instruction encodings on page F2-2408](#). This applies to all instructions except those with the cond field equal to 0b1111.

[Table F4-1](#) shows the top-level encoding of the A32 instruction set, including the cases where bits[31:28] are defined as 0b1111 rather than as the cond.

The behavior of an attempt to execute an unallocated instruction is described in [UNDEFINED, UNPREDICTABLE, and CONSTRAINED UNPREDICTABLE instruction set space on page F2-2414](#).

For more information on A32 instruction encodings see [Chapter F2 About the T32 and A32 Instruction Descriptions](#).

Table F4-1 Main encoding table for the A32 instruction set

| Decode fields | | | Decode group or instruction page |
|---------------|-----|-----|---|
| cond | op0 | op1 | |
| != 1111 | 00x | - | <i>Data-processing and miscellaneous instructions on page F4-2502</i> |
| != 1111 | 010 | - | <i>Load/Store Word, Unsigned byte (immediate, literal) on page F4-2519</i> |
| != 1111 | 011 | 0 | <i>Load/Store Word, Unsigned byte (register) on page F4-2520</i> |
| != 1111 | 011 | 1 | <i>Media instructions on page F4-2521</i> |
| - | 10x | - | <i>Branch, branch with link, and block data transfer on page F4-2529</i> |
| - | 11x | - | <i>System register access, Advanced SIMD, floating-point, and Supervisor Call on page F4-2531</i> |
| 1111 | 0xx | - | <i>Unconditional instructions on page F4-2540</i> |

F4.1.1 About the A32 Advanced SIMD and floating-point instructions and their encodings

The Advanced SIMD and floating-point instructions are common to the A32 and T32 instruction sets. These instructions perform Advanced SIMD and floating-point operations on a common register file, the SIMD&FP register file. This means:

- In general, the instructions that load or store registers in this file, or move data between general-purpose registers and this register file, are common to the Advanced SIMD and floating-point instructions.
- There are distinct Advanced SIMD data-processing instructions and floating-point data-processing instructions.

Different groups of the A32 Advanced SIMD and floating-point instructions are decoded from different points in the A32 instruction decode structure. [Table F4-2 on page F4-2501](#) shows these instruction groups, and where each group is decoded from the overall A32 decode structure:

Table F4-2 Advanced SIMD and floating-point instructions in the A32 decode structure

| Advanced SIMD and floating-point instruction group | A32 decode is from |
|--|---|
| <i>Advanced SIMD data-processing on page F4-2541</i> | <i>Unconditional instructions on page F4-2540</i> |
| <i>Floating-point data-processing on page F4-2533</i> | <i>System register access, Advanced SIMD, floating-point, and Supervisor Call on page F4-2531</i> |
| <i>Floating-point and Advanced SIMD 32-bit register moves on page F4-2536</i> | <i>System register access, Advanced SIMD, floating-point, and Supervisor Call on page F4-2531</i> |
| <i>Floating-point and Advanced SIMD Load/Store and 64-bit register moves on page F4-2531</i> | <i>System register access, Advanced SIMD, floating-point, and Supervisor Call on page F4-2531</i> |
| <i>Advanced SIMD element or structure Load/Store on page F4-2553</i> | <i>Unconditional instructions on page F4-2540</i> |

F4.2 Data-processing and miscellaneous instructions

This section describes the encoding of the Data-processing and miscellaneous instructions group. This section is decoded from *Top level A32 instruction set encoding* on page F4-2500.

| Decode fields | | | | | Decode group or instruction page |
|---------------|----------|-----|-------|-----|---|
| op0 | op1 | op2 | op3 | op4 | |
| 0 | - | 1 | != 00 | 1 | Extra Load/Store |
| 0 | 0xxxx | 1 | 00 | 1 | Multiply and Accumulate on page F4-2505 |
| 0 | 1xxxx | 1 | 00 | 1 | Synchronization primitives and Load-Acquire/Store-Release on page F4-2506 |
| 0 | 10xx0 | 0 | - | - | Miscellaneous on page F4-2507 |
| 0 | 10xx0 | 1 | - | 0 | Halfword Multiply and Accumulate on page F4-2510 |
| 0 | != 10xx0 | - | - | 0 | Data-processing register (immediate shift) on page F4-2511 |
| 0 | != 10xx0 | 0 | - | 1 | Data-processing register (register shift) on page F4-2513 |
| 1 | - | - | - | - | Data-processing immediate on page F4-2515 |

F4.2.1 Extra Load/Store

This section describes the encoding of the Extra Load/Store group. This section is decoded from *Data-processing and miscellaneous instructions*.

| Decode fields | | Decode group or instruction page |
|---------------|--|---|
| op0 | | |
| 0 | | Load/Store Dual, Half, Signed byte (register) on page F4-2503 |
| 1 | | Load/Store Dual, Half, Signed byte (immediate, literal) on page F4-2504 |

Load/Store Dual, Half, Signed byte (register)

This section describes the encoding of the Load/Store Dual, Half, Signed byte (register) instruction class. This section is decoded from *Extra Load/Store* on page F4-2502.

| Decode fields | | | | Instruction Page |
|---------------|-----|---|---|---|
| o1 | op2 | P | W | |
| 0 | 01 | 0 | 0 | STRH (register) - Post-indexed variant |
| 0 | 01 | 0 | 1 | STRHT |
| 0 | 01 | 1 | - | STRH (register) - Pre-indexed variant |
| 0 | 10 | 0 | 0 | LDRD (register) - Post-indexed variant |
| 0 | 10 | 0 | 1 | Unallocated. |
| 0 | 10 | 1 | - | LDRD (register) - Pre-indexed variant |
| 0 | 11 | 0 | 0 | STRD (register) - Post-indexed variant |
| 0 | 11 | 0 | 1 | Unallocated. |
| 0 | 11 | 1 | - | STRD (register) - Pre-indexed variant |
| 1 | 01 | 0 | 0 | LDRH (register) - Post-indexed variant |
| 1 | 01 | 0 | 1 | LDRHT |
| 1 | 01 | 1 | - | LDRH (register) - Pre-indexed variant |
| 1 | 10 | 0 | 0 | LDRSB (register) - Post-indexed variant |
| 1 | 10 | 0 | 1 | LDRSBT |
| 1 | 10 | 1 | - | LDRSB (register) - Pre-indexed variant |
| 1 | 11 | 0 | 0 | LDRSH (register) - Post-indexed variant |
| 1 | 11 | 0 | 1 | LDRSHT |
| 1 | 11 | 1 | - | LDRSH (register) - Pre-indexed variant |

Load/Store Dual, Half, Signed byte (immediate, literal)

This section describes the encoding of the Load/Store Dual, Half, Signed byte (immediate, literal) instruction class. This section is decoded from *Extra Load/Store* on page F4-2502.

| Decode fields | | | | Instruction Page |

| 1101 | 0 | VQDMULL |
| 1101 | 1 | Unallocated. |
| 1111 | - | Unallocated. |

Advanced SIMD two registers and a scalar

This section describes the encoding of the Advanced SIMD two registers and a scalar instruction class. This section is decoded from *Advanced SIMD data-processing* on page F4-2541.

| Decode fields | | Instruction Page |
|---------------|---|-------------------|
| opc | Q | |
| 000x | - | VMLA (by scalar) |
| 0010 | - | VMLAL (by scalar) |
| 0011 | 0 | VQDMLAL |
| 0011 | 1 | Unallocated. |
| 010x | - | VMLS (by scalar) |
| 0110 | - | VMLSL (by scalar) |
| 0111 | 0 | VQDMLSL |
| 0111 | 1 | Unallocated. |
| 100x | - | VMUL (by scalar) |
| 1010 | - | VMULL (by scalar) |
| 1011 | 0 | VQDMULL |
| 1011 | 1 | Unallocated. |
| 1100 | - | VQDMULH |
| 1101 | - | VQRDMULH |
| 111x | - | Unallocated. |

Advanced SIMD two registers and shift amount

This section describes the encoding of the Advanced SIMD two registers and shift amount instruction class. This section is decoded from *Advanced SIMD data-processing* on page F4-2541. This decode imposes the constraint that imm3H:L != '0000'.

| | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|-------|-------|----|-----|----|----|----|---|----|---|---|---|---|---|

| 111x | 0 | - | - | - | VCVT (between floating-point and fixed-point, Advanced SIMD) |

F4.8.3 Memory hints and barriers

This section describes the encoding of the Memory hints and barriers group. This section is decoded from *Unconditional instructions* on page F4-2540.

| Decode fields | | Decode group or instruction page |
|---------------|-----|--|
| op0 | op1 | |
| 00x11 | - | UNPREDICTABLE. |
| 01011 | - | <i>Barriers</i> |
| 01111 | - | UNPREDICTABLE. |
| 0xx01 | - | UNPREDICTABLE. |
| 0xxx0 | - | <i>Preload (immediate)</i> on page F4-2552 |
| 1xxx0 | 0 | <i>Preload (register)</i> on page F4-2552 |
| 1xxx1 | 0 | UNPREDICTABLE. |
| 1xxxx | 1 | Unallocated. |

Barriers

This section describes the encoding of the Barriers instruction class. This section is decoded from *Memory hints and barriers*.

| Decode fields | | Instruction Page |
|---------------|--|------------------|
| opcode | | |
| 0000 | | UNPREDICTABLE. |
| 0001 | | <i>CLREX</i> |
| 001x | | UNPREDICTABLE. |
| 0100 | | <i>DSB</i> |
| 0101 | | <i>DMB</i> |
| 0110 | | <i>ISB</i> |
| 0111 | | UNPREDICTABLE. |
| 1xxx | | UNPREDICTABLE. |

Preload (immediate)

This section describes the encoding of the Preload (immediate) instruction class. This section is decoded from [Memory hints and barriers on page F4-2551](#).

| Decode fields | | | Instruction Page |
|---------------|---|---------|---|
| D | R | Rn | |
| 0 | 0 | - | Reserved hint, behaves as NOP . |
| 0 | 1 | - | PLI (immediate, literal) |
| 1 | - | 1111 | PLD (literal) |
| 1 | 0 | != 1111 | PLD, PLDW (immediate) - Preload write variant |
| 1 | 1 | != 1111 | PLD, PLDW (immediate) - Preload read variant |

Preload (register)

This section describes the encoding of the Preload (register) instruction class. This section is decoded from [Memory hints and barriers on page F4-2551](#).

| Decode fields | | Instruction Page |
|---------------|---|--|
| o2 | D | |
| 0 | 0 | Reserved hint, behaves as NOP . |
| 0 | 1 | PLD, PLDW (register) - Preload write, rotate right with extend variant |
| 1 | 0 | PLI (register) |
| 1 | 1 | PLD, PLDW (register) - Preload read, rotate right with extend variant |

F4.8.4 Advanced SIMD element or structure Load/Store

This section describes the encoding of the Advanced SIMD element or structure Load/Store group. This section is decoded from *Unconditional instructions* on page F4-2540.

Decode fields

| Decode fields | | | Decode group or instruction page |
|---------------|-------|---------|---|
| op0 | op1 | op2 | |
| 0 | - | 1101 | Advanced SIMD Load/Store multiple structures (immediate, post-indexed) |
| 0 | - | 1111 | Advanced SIMD Load/Store multiple structures (no writeback) on page F4-2554 |
| 0 | - | != 11x1 | Advanced SIMD Load/Store multiple structures (register, post-indexed) on page F4-2555 |
| 1 | 11 | 1101 | Advanced SIMD load single structure to all lanes (immediate, post-indexed) on page F4-2556 |
| 1 | 11 | 1111 | Advanced SIMD load single structure to all lanes (no writeback) on page F4-2556 |
| 1 | 11 | != 11x1 | Advanced SIMD load single structure to all lanes (register, post-indexed) on page F4-2557 |
| 1 | != 11 | 1101 | Advanced SIMD Load/Store single structure to one lane (immediate, post-indexed) on page F4-2557 |
| 1 | != 11 | 1111 | Advanced SIMD Load/Store single structure to one lane (no writeback) on page F4-2558 |
| 1 | != 11 | != 11x1 | Advanced SIMD Load/Store single structure to one lane (register, post-indexed) on page F4-2558 |

Advanced SIMD Load/Store multiple structures (immediate, post-indexed)

This section describes the encoding of the Advanced SIMD Load/Store multiple structures (immediate, post-indexed) instruction class. This section is decoded from *Advanced SIMD element or structure Load/Store*.

Decode fields

| Decode fields | | Instruction Page |
|---------------|----------------------|---|
| L | type | |
| 0 | 0010 011x 1010 | VST1 (multiple single elements) - Post-indexed variant |
| 0 | 0011 100x | VST2 (multiple 2-element structures) - Post-indexed variant |
| 0 | 000x | VST4 (multiple 4-element structures) - Post-indexed variant |
| 0 | 010x | VST3 (multiple 3-element structures) - Post-indexed variant |

| Decode fields | | | Instruction Page |
|---------------|----------------------|---|------------------|
| L | type | | |
| 1 | 0010 011x 1010 | VLD1 (multiple single elements) - Post-indexed variant | |
| 1 | 0011 100x | VLD2 (multiple 2-element structures) - Post-indexed variant | |
| 1 | 000x | VLD4 (multiple 4-element structures) - Post-indexed variant | |
| 1 | 010x | VLD3 (multiple 3-element structures) - Post-indexed variant | |
| - | 1011 | Unallocated. | |
| - | 11xx | Unallocated. | |

Advanced SIMD Load/Store multiple structures (no writeback)

This section describes the encoding of the Advanced SIMD Load/Store multiple structures (no writeback) instruction class. This section is decoded from *Advanced SIMD element or structure Load/Store* on page F4-2553.

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|------|-------|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 1 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | D | L | 0 | Rn | Vd | type | size | align | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

| Decode fields | | | Instruction Page |
|---------------|----------------------|---|------------------|
| L | type | | |
| 0 | 0010 011x 1010 | VST1 (multiple single elements) - Offset variant | |
| 0 | 0011 100x | VST2 (multiple 2-element structures) - Offset variant | |
| 0 | 000x | VST4 (multiple 4-element structures) - Offset variant | |

Advanced SIMD Load/Store single structure to one lane (register, post-indexed)

This section describes the encoding of the Advanced SIMD Load/Store single structure to one lane (register, post-indexed) instruction class. This section is decoded from *Advanced SIMD element or structure Load/Store* on page F4-2553.

| Decode fields | | Instruction Page |
|---------------|----|---|
| L | N | |
| 0 | 00 | VST1 (single element from one lane) |
| 0 | 01 | VST2 (single 2-element structure from one lane) |
| 0 | 10 | VST3 (single 3-element structure from one lane) |

| 1 | 11 | VLD4 (single 4-element structure to one lane) |

Chapter F5

T32 and A32 Base Instruction Set Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- *Alphabetical list of T32 and A32 base instruction set instructions on page F5-2560.*
- *Encoding and use of Banked register transfer instructions on page F5-3228.*

F5.1 Alphabetical list of T32 and A32 base instruction set instructions

This section lists every instruction in the T32 and A32 base instruction sets. For details of the format used see [Format of instruction descriptions on page F2-2402](#).

This section is formatted so that each instruction description starts on a new page.

F5.1.1 ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from **SPSR_<current_mode>**.
 - The PE checks **SPSR_<current_mode>** for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

ADC variant

Applies when $S == 0$.

ADC{<c>}{<q>} {<Rd>}, <Rn>, #<const>

ADCS variant

Applies when $S == 1$.

ADCS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

$d = \text{UInt}(Rd)$; $n = \text{UInt}(Rn)$; $\text{setflags} = (S == '1')$; $\text{imm32} = \text{A32ExpandImm}(\text{imm12})$;

T1

ADC variant

Applies when $S == 0$.

ADC{<c>}{<q>} {<Rd>}, <Rn>, #<const>

ADCS variant

Applies when $S == 1$.

ADCS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);  
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    (result, nzcvc) = AddWithCarry(R[n], imm32, PSTATE.C);  
    if d == 15 then // Can only occur for A32 encoding  
        if setflags then  
            ALUExceptionReturn(result);  
        else  
            ALUWritePC(result);  
    else  
        R[d] = result;  
        if setflags then  
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.2 ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

| | | | | | |
|--------|-------------------------------|-------|-------|-------------|-------------|
| 31 | 28 27 26 25 24 23 22 21 20 19 | 16 15 | 12 11 | 7 6 5 4 3 | 0 |

| cond | | | | | |

ADC, rotate right with extend variant

Applies when $S == 0$ && $imm5 == 00000$ && $type == 11$.

ADC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ADC, shift or rotate by value variant

Applies when $S == 0$ && $!(imm5 == 00000 \ \&\& \ type == 11)$.

ADC{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

ADCS, rotate right with extend variant

Applies when $S == 1$ && $imm5 == 00000$ && $type == 11$.

ADCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ADCS, shift or rotate by value variant

Applies when $S == 1$ && $!(imm5 == 00000 \ \&\& \ type == 11)$.

ADCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

T1

| | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|----|-----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 3 | 2 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | Rm | Rdn | | |

T1 variant

ADC<c>{<q>} {<Rdn>}, <Rdn>, <Rm> // Inside IT block
 ADCS{<q>} {<Rdn>}, <Rdn>, <Rm> // Outside IT block

Decode for this encoding

d = UInt(Rdn); n = UInt(Rdn); m = UInt(Rm); setflags = !InITBlock();
 (shift_t, shift_n) = (SRTYPE_LSL, 0);

T2

| | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|------|----|------|------|----|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

ADC, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && type == 11.

ADC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ADC, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && type == 11).

ADC<c>.W {<Rd>}, <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
 ADC{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

ADCS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && imm2 == 00 && type == 11.

ADCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ADCS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && type == 11).

ADCS.W {<Rd>}, <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
 ADCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
 (shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | | | | | |
|----------|---|-----|----------------|-----|----------------|-----|----------------|-----|----------------|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rdn> | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field. | | | | | | | | |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none"> For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. | | | | | | | | |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(R[n], shifted, PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else

```

```
        ALUwritePC(result);  
else  
    R[d] = result;  
    if setflags then  
        PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.3 ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|------|---|----|---|---|---|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |
| !=1111 | | | | 0 | 0 | 0 | 0 | 1 | 0 | 1 | S | Rn | Rd | Rs | 0 | type | 1 | Rm | | | | |
| cond | | | | | | | | | | | | | | | | | | | | | | |

Flag setting variant

Applies when S == 1.

ADC{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

ADC{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzc;
```

F5.1.4 ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

if Rn == '1101' then SEE ADD (SP plus immediate);
d = UInt(Rd); n = UInt(Rn); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|---------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rdn> | Is the general-purpose source and destination register, encoded in the "Rdn" field. |
| <imm8> | Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used: <ul style="list-style-type: none"> For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of this instruction. |
| | For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. |
| <Rn> | For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate) . If the PC is used, see ADR . For encoding T1: is the general-purpose source register, encoded in the "Rn" field. For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD, ADDS (SP plus immediate) . |
| <imm3> | Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field. |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field. |
| <const> | For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-2422 for the range of values. For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F2-2420 for the range of values. |

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the ADDW syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(R[n], imm32, '0');
    if d == 15 then // Can only occur for A32 encoding
      if setflags then
```

```
        ALUExceptionReturn(result);
    else
        ALUWritePC(result);
else
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcvc;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcvc) = AddWithCarry(R[n], imm32, '0');
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.5 ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

| | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|---------|----|----|----|---------|----|----|----|--------|----|----|---|------|---|------|---|---|----|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 | |

(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rdn> Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#). The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of this instruction.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and:

- If omitted, this register is the same as <Rn>.
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see [ADD, ADDS \(SP plus register\)](#).

- For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.
- For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see [ADD, ADDS \(SP plus register\)](#).
- <Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
- For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.
- For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
- For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Inside an IT block, if `ADD<c> <Rd>, <Rn>, <Rd>` cannot be assembled using encoding T1, it is assembled using encoding T2 as though `ADD<c> <Rd>, <Rn>` had been written. To prevent this happening, use the `.W` qualifier.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzc;
```

F5.1.6 ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|------|---|----|---|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| !=1111 | | | | 0 | 0 | 0 | 0 | 1 | 0 | 0 | S | Rn | Rd | Rs | 0 | type | 1 | Rm | | | |
| cond | | | | | | | | | | | | | | | | | | | | | |

Flag setting variant

Applies when S == 1.

ADDS{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

ADD{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|--------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rn> | Is the first general-purpose source register, encoded in the "Rn" field. |
| <Rm> | Is the second general-purpose source register, encoded in the "Rm" field. |
| <type> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzc;
```

F5.1.7 ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

ADD variant

Applies when `S == 0`.

ADD{<c>}{<q>} {<Rd>}, SP, #<const>

ADDS variant

Applies when `S == 1`.

ADDS{<c>}{<q>} {<Rd>}, SP, #<const>

Decode for all variants of this encoding

`d = UInt(Rd); setflags = (S == '1'); imm32 = A32ExpandImm(imm12);`

T1

T1 variant

ADD{<c>}{<q>} <Rd>, SP, #<imm8>

Decode for this encoding

`d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(imm8:'00', 32);`

T2

T2 variant

ADD{<c>}{<q>} {<Rd>,} SP, #<imm7>

Decode for this encoding

d = 13; setflags = FALSE; imm32 = ZeroExtend(imm7:'00', 32);

T3

ADD variant

Applies when S == 0.

ADD{<c>}.W {<Rd>,} SP, #<const> // <Rd>, <const> can be represented in T1 or T2
 ADD{<c>}{<q>} {<Rd>,} SP, #<const>

ADDS variant

Applies when S == 1 && Rd != 1111.

ADDS{<c>}{<q>} {<Rd>,} SP, #<const>

Decode for all variants of this encoding

if Rd == '1111' && S == '1' then SEE CMN (immediate);
 d = UInt(Rd); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);
 if d == 15 && !setflags then UNPREDICTABLE;

T4

T4 variant

ADD{<c>}{<q>} {<Rd>,} SP, #<imm12> // <imm12> cannot be represented in T1, T2, or T3
 ADDW{<c>}{<q>} {<Rd>,} SP, #<imm12> // <imm12> can be represented in T1, T2, or T3

Decode for this encoding

d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
 if d == 15 then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors.](#)

Assembler symbols

| | |
|---------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <imm7> | Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4. |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none">• For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293.• For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. <p>For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.</p> <p>For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.</p> |
| <imm8> | Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4. |
| <imm12> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field. |
| <const> | For encoding A1: an immediate value. See Modified immediate constants in A32 instructions on page F2-2422 for the range of values. For encoding T3: an immediate value. See Modified immediate constants in T32 instructions on page F2-2420 for the range of values. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(SP, imm32, '0');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.8 ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

T2 variant

ADD{<c>}{<q>} {SP,} SP, <Rm>

Decode for this encoding

```
if Rm == '1101' then SEE encoding T1;
d = 13; m = UInt(Rm); setflags = FALSE;
(shift_t, shift_n) = (SRTYPE_LSL, 0);
```

T3

ADD, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && type == 11.

ADD{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

ADD, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && type == 11).

ADD{<c>}.W {<Rd>}, SP, <Rm> // <Rd>, <Rm> can be represented in T1 or T2
 ADD{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

ADDS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && type == 11.

ADDS{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

ADDS, shift or rotate by value variant

Applies when $S == 1 \ \&\& \ !(imm3 == 000 \ \&\& \ imm2 == 00 \ \&\& \ type == 11) \ \&\& \ Rd \ != \ 1111$.

ADDS{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE CMN (register);
d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && !setflags) || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rdm> Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:
 - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
 - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.
- <Rm> For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
 For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

| | |
|-----|----------------|
| LSL | when type = 00 |
| LSR | when type = 01 |
| ASR | when type = 10 |
| ROR | when type = 11 |
- <amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
 For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.9 ADD (immediate, to PC)

Add to PC adds an immediate value to the $\text{Align}(\text{PC}, 4)$ value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias

This instruction is a pseudo-instruction of the [ADR](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADR](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [ADR](#) gives the operational pseudocode for this instruction.

A1

A1 variant

$\text{ADD}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \text{PC}, \#\langle \text{const} \rangle$

is equivalent to

$\text{ADR}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \langle \text{label} \rangle$

and is never the preferred disassembly.

T1

T1 variant

$\text{ADD}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \text{PC}, \#\langle \text{imm8} \rangle$

is equivalent to

$\text{ADR}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \langle \text{label} \rangle$

and is never the preferred disassembly.

T3

T3 variant

$\text{ADDW}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \text{PC}, \#\langle \text{imm12} \rangle // \langle Rd \rangle, \langle \text{imm12} \rangle$ can be represented in T1

is equivalent to

$\text{ADR}\{\langle c \rangle\}\{\langle q \rangle\} \langle Rd \rangle, \langle \text{label} \rangle$

and is never the preferred disassembly.

ADD{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is never the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset. If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions on page F2-2422](#).

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset. If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are 0-4095.

<imm8> Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as `<imm8>/4`.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> An immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

Operation for all encodings

The description of [ADR](#) gives the operational pseudocode for this instruction.

F5.1.10 ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the pseudo-instructions **ADD (immediate, to PC)** and **SUB (immediate, from PC)**. The pseudo-instruction is never the preferred disassembly.

A1

A1 variant

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

d = UInt(Rd); imm32 = A32ExpandImm(imm12); add = TRUE;

A2

A2 variant

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

d = UInt(Rd); imm32 = A32ExpandImm(imm12); add = FALSE;

T1

T1 variant

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

d = UInt(Rd); imm32 = ZeroExtend(imm8:'00', 32); add = TRUE;

T2

T2 variant

ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
d = UInt(Rd); imm32 = ZeroExtend(i:imm3:imm8, 32); add = FALSE;
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

T3

| | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|----|------|----|------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 12 | 11 | 8 | 7 | 0 |
| 1 | 1 | 1 | 1 | 0 | i | 1 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | imm3 | Rd | imm8 | | | |

T3 variant

ADR{<c>}.W <Rd>, <label> // <Rd>, <label> can be presented in T1
 ADR{<c>}{<q>} <Rd>, <label>

Decode for this encoding

```
d = UInt(Rd); imm32 = ZeroExtend(i:imm3:imm8, 32); add = TRUE;
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias or pseudo-instruction | of variant | is preferred when |
|--|------------|-------------------------------|
| ADD (immediate, to PC) | - | Never |
| SUB (immediate, from PC) | T2 | i:imm3:imm8 == '000000000000' |
| SUB (immediate, from PC) | A2 | imm12 == '000000000000' |

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the A1ign(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset. If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32. Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions on page F2-2422](#).

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset. If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

F5.1.11 AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from **SPSR_<current_mode>**.
 - The PE checks **SPSR_<current_mode>** for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

AND variant

Applies when S == 0.

AND{<c>}{<q>} {<Rd>}, <Rn>, #<const>

ANDS variant

Applies when S == 1.

ANDS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
 (imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);

T1

AND variant

Applies when S == 0.

AND{<c>}{<q>} {<Rd>}, <Rn>, #<const>

ANDS variant

Applies when S == 1 && Rd != 1111.

ANDS{<c>}{<q>} {<Rd>,<Rn>, #<const>

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE TST (immediate);
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:
 - For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
 - For the ANDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  result = R[n] AND imm32;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged
```

F5.1.12 AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | | | | | |
|----------|---|-----|----------------|-----|----------------|-----|----------------|-----|----------------|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rdn> | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field. | | | | | | | | |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none"> For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the ANDS variant, the instruction performs an exception return, that restores <code>PSTATE</code> from <code>SPSR_<current_mode></code>. <p>For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.</p> | | | | | | | | |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

In T32 assembly:

- Outside an IT block, if `ANDS <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ANDS <Rd>, <Rn>` had been written.
- Inside an IT block, if `AND<c> <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `AND<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the `.W` qualifier.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else

```

```
        ALUwritePC(result);  
else  
    R[d] = result;  
    if setflags then  
        PSTATE.N = result<31>;  
        PSTATE.Z = IsZeroBit(result);  
        PSTATE.C = carry;  
        // PSTATE.V unchanged
```

F5.1.13 AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| | | | | | | | | | | | | | | | | | | | | | |

| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. | | | | | | | | |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.14 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

This instruction is an alias of the [MOV, MOVS \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

ASR{<C>}{<q>} {<Rd>}, <Rm>, <Rs>

is equivalent to

MOV{<C>}{<q>} <Rd>, <Rm>, ASR <Rs>

and is always the preferred disassembly.

Assembler symbols

<C> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rdm> Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the first general-purpose source register, encoded in the "Rm" field.

<Rs> Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

F5.1.16 ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the [MOV, MOVS \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

A1

MOVS, shift or rotate by value variant

ASRS{<c>}{<q>} {<Rd>}, <Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

T2

T2 variant

ASRS{<q>} {<Rd>}, <Rm>, #<imm> // Outside IT block

is equivalent to

MOVS{<q>} <Rd>, <Rm>, ASR #<imm>

and is the preferred disassembly when !InITBlock().

T3

MOVS, shift or rotate by value variant

ASRS.W {<Rd>,} <Rm>, #<imm> // Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2 is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

ASRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ASR #<imm>

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from [SPSR_<current_mode>](#).

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

<imm> For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation for all encodings

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

F5.1.17 ASRS (register)

Arithmetic Shift Right, setting flags (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, writes the result to the destination register, and updates the condition flags based on the result. The variable number of bits is read from the bottom byte of a register

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

F5.1.18 B

Branch causes a branch to a target address.

A1

A1 variant

B{<c>}{<q>} <label>

Decode for this encoding

imm32 = SignExtend(imm24:'00', 32);

T1

T1 variant

B<c>{<q>} <label> // Not permitted in IT block

Decode for this encoding

if cond == '1110' then SEE UDF;
 if cond == '1111' then SEE SVC;
 imm32 = SignExtend(imm8:'0', 32);
 if InITBlock() then UNPREDICTABLE;

T2

T2 variant

B{<c>}{<q>} <label> // Outside or last in IT block

Decode for this encoding

imm32 = SignExtend(imm11:'0', 32);
 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

T3

T3 variant

B<c>.W <label> // Not permitted in IT block, and <label> can be represented in T1
 B<c>{<q>} <label> // Not permitted in IT block

Decode for this encoding

```
if cond<3:1> == '111' then SEE "Related encodings";
imm32 = SignExtend(S:J2:J1:imm6:imm11:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

T4

T4 variant

B{<c>}.W <label> // <label> can be represented in T2
 B{<c>}{<q>} <label>

Decode for this encoding

```
I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Branches and miscellaneous control on page F3-2471](#).

Assembler symbols

- <c> For encoding A1, T2 and T4: see [Standard assembler syntax fields on page F2-2406](#).
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#). Must not be AL or omitted.
 For encoding T3: see [Standard assembler syntax fields on page F2-2406](#). <c> must not be AL or omitted.
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
 For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254.
 For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –2048 to 2046.
 For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –1048576 to 1048574.

For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets `imm32` to that offset. Permitted offsets are even numbers in the range `-16777216` to `16777214`.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32);
```

F5.1.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

A1

A1 variant

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

d = UInt(Rd); msbit = UInt(msb); lsb = UInt(lsb);
 if d == 15 then UNPREDICTABLE;

T1

T1 variant

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

d = UInt(Rd); msbit = UInt(msb); lsb = UInt(imm3:imm2);
 if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <lsb> For encoding A1: is the least significant bit to be cleared, in the range 0 to 31, encoded in the "lsb" field.
 For encoding T1: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.
- <width> Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = Replicate('0', msbit-lsbit+1);
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $msbit < lsbit$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

F5.1.20 BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

A1

A1 variant

BFI{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
if Rn == '1111' then SEE BFC;
d = UInt(Rd); n = UInt(Rn); msbit = UInt(msb); lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

T1

T1 variant

BFI{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
if Rn == '1111' then SEE BFC;
d = UInt(Rd); n = UInt(Rn); msbit = UInt(msb); lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.
- <lsb> For encoding A1: is the least significant destination bit, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the least significant destination bit, in the range 0 to 31, encoded in the "imm3:imm2" field.
- <width> Is the number of bits to be copied, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = R[n]<(msbit-lsbit):0>;
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $msbit < lsbit$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

F5.1.21 BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores **PSTATE** from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

BIC variant

Applies when $S == 0$.

`BIC{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

BICS variant

Applies when $S == 1$.

`BICS{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

BIC variant

Applies when $S == 0$.

`BIC{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

BICS variant

Applies when $S == 1$.

BICS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the BICS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  result = R[n] AND NOT(imm32);
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged
```

F5.1.22 BIC, BICS (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

BIC, rotate right with extend variant

Applies when `S == 0` && `imm5 == 00000` && `type == 11`.

`BIC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX`

BIC, shift or rotate by value variant

Applies when `S == 0` && `!(imm5 == 00000 && type == 11)`.

`BIC{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}`

BICS, rotate right with extend variant

Applies when `S == 1` && `imm5 == 00000` && `type == 11`.

`BICS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX`

BICS, shift or rotate by value variant

Applies when `S == 1` && `!(imm5 == 00000 && type == 11)`.

`BICS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}`

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

T1

| | | | | | | | | | | | | | |

| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
  
```

F5.1.23 BIC, BICS (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

Flag setting variant

Applies when S == 1.

BICS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

BIC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.24 BKPT

Breakpoint causes a Breakpoint Instruction exception.

Breakpoint is always unconditional, even when inside an IT block.

A1

A1 variant

BKPT{<q>} {#}<imm>

Decode for this encoding

```
imm16 = imm12:imm4;
if cond != '1110' then UNPREDICTABLE; // BKPT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

T1 variant

BKPT{<q>} {#}<imm>

Decode for this encoding

```
imm16 = ZeroExtend(imm8, 16);
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<q> See [Standard assembler syntax fields on page F2-2406](#). An BKPT instruction must be unconditional.

- <imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value:
- Is recorded in the Comment field of [ESR_ELx.ISS](#) if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
 - Is ignored otherwise.
- For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:
- Is recorded in the Comment field of [ESR_ELx.ISS](#) if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
 - Is ignored otherwise.

Operation for all encodings

```
EncodingSpecificOperations();  
AArch32.SoftwareBreakpoint(imm16);
```

F5.1.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

A1

A1 variant

BL{<c>}{<q>} <label>

Decode for this encoding

imm32 = [SignExtend](#)(imm24:'00', 32); targetInstrSet = [InstrSet_A32](#);

A2

A2 variant

BLX{<c>}{<q>} <label>

Decode for this encoding

imm32 = [SignExtend](#)(imm24:H:'0', 32); targetInstrSet = [InstrSet_T32](#);

T1

T1 variant

BL{<c>}{<q>} <label>

Decode for this encoding

I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = [SignExtend](#)(S:I1:I2:imm10:imm11:'0', 32);
 targetInstrSet = [InstrSet_T32](#);
 if [InITBlock](#)() && ![LastInITBlock](#)() then UNPREDICTABLE;

T2

T2 variant

BLX{<c>}{<q>} <label>

Decode for this encoding

```
if H == '1' then UNDEFINED;
I1 = NOT(J1 EOR S); I2 = NOT(J2 EOR S); imm32 = SignExtend(S:I1:I2:imm10H:imm10L:'00', 32);
targetInstrSet = InstrSet_A32;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1, T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
For encoding A2: see [Standard assembler syntax fields on page F2-2406](#). <c> must be AL or omitted.
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.
For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –33554430 to 33554430.
For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.
For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_A32 then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress);
```

F5.1.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address specified in the register, and if necessary changes to the instruction set indicated by bit[0] of the register value. If the value in bit[0] is 0, the instruction set after the branch will be A32. If the value in bit[0] is 1, the instruction set after the branch will be T32.

A1

A1 variant

BLX{<c>}{<q>} <Rm>

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

T1

T1 variant

BLX{<c>}{<q>} <Rm>

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  target = R[m];
  if CurrentInstrSet() == InstrSet_A32 then
    next_instr_addr = PC - 4;
    LR = next_instr_addr;
  else
```

```
next_instr_addr = PC - 2;  
LR = next_instr_addr<31:1> : '1';  
BXWritePC(target);
```

F5.1.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|---|---|---|---|----|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |

| cond | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

BX{<c>}{<q>} <Rm>

Decode for this encoding

m = UInt(Rm);

T1

| | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|----|-----|-----|-----|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 3 | 2 | 1 | 0 |
| 0 | 1 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | Rm | (0) | (0) | (0) | |

T1 variant

BX{<c>}{<q>} <Rm>

Decode for this encoding

m = UInt(Rm);
 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rm> For encoding A1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

For encoding T1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

Note

If <Rm> is the PC at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the BXwritePC() pseudocode function has bits<1:0> = '10'.

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    BXWritePC(R[m]);
```

F5.1.28 BXJ

Branch and Exchange, previously Branch and Exchange Jazelle.

In ARMv8, BXJ behaves as a BX instruction, see [BX](#). This means it causes a branch to an address and instruction set specified by a register.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

T1 variant

BXJ{<c>}{<q>} <Rm>

Decode for this encoding

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

F5.1.29 CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

T1

| | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|------|--|--|---|----|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | | | 3 | 2 | 0 |
| 1 | 0 | 1 | 1 | op | 0 | i | 1 | | imm5 | | | | Rn | |

CBNZ variant

Applies when `op == 1`.

CBNZ{<q>} <Rn>, <label>

CBZ variant

Applies when `op == 0`.

CBZ{<q>} <Rn>, <label>

Decode for all variants of this encoding

```
n = UInt(Rn); imm32 = ZeroExtend(i:imm5:'0', 32); nonzero = (op == '1');
if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rn> Is the general-purpose register to be tested, encoded in the "Rn" field.

<label> Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 and in the range 0 to 126, is encoded as "i:imm5" times 4.

Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R[n]) then
    BranchWritePC(PC + imm32);
```

F5.1.30 CLREX

Clear-Exclusive clears the local monitor of the executing PE.

T1 variant

CLREX{<c>}{<q>}

Decode for this encoding

// No additional decoding required

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). Must be AL or omitted.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
```

F5.1.31 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

A1

A1 variant

CLZ{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);
 if d == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

CLZ{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); n = UInt(Rn);
 if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
```

F5.1.32 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn); imm32 = A32ExpandImm(imm12);

T1

T1 variant

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn); imm32 = T32ExpandImm(i:imm3:imm8);
 if n == 15 then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
 For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.
 For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(R[n], imm32, '0');
    PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.33 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|------|------|---|----|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 |

Rotate right with extend variant

Applies when imm3 == 000 && imm2 == 00 && type == 11.

CMN{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm3 == 000 && imm2 == 00 && type == 11).

CMN{<c>}.W <Rn>, <Rm> // <Rn>, <Rm> can be represented in T1
CMN{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm);  
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);  
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|----------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field. |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. |

Operation for all encodings

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);  
  (result, nzcV) = AddWithCarry(R[n], shifted, '0');  
  PSTATE.<N,Z,C,V> = nzcV;
```

F5.1.34 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

CMN{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.35 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

CMP{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn); imm32 = A32ExpandImm(imm12);

T1

T1 variant

CMP{<c>}{<q>} <Rn>, #<imm8>

Decode for this encoding

n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);

T2

T2 variant

CMP{<c>}.W <Rn>, #<const> // <Rd>, <const> can be represented in T1

CMP{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn); imm32 = T32ExpandImm(i:imm3:imm8);
 if n == 15 then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1: is a general-purpose source register, encoded in the "Rn" field.
For encoding T2: is the general-purpose source register, encoded in the "Rn" field.
- <imm8> Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.
For encoding T2: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
(result, nzc) = AddWithCarry(R[n], NOT(imm32), '1');
PSTATE.<N,Z,C,V> = nzc;
```

F5.1.36 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|------|------|---|----|---|---|--|

| cond | | | | | | | | | | | | | | | | | | | | | | | |

Rotate right with extend variant

Applies when imm5 == 00000 && type == 11.

CMP{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm5 == 00000 && type == 11).

CMP{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

T1

| | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|----|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 3 | 2 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | Rm | Rn | | |

T1 variant

CMP{<c>}{<q>} <Rn>, <Rm> // <Rn> and <Rm> both from R0-R7

Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm);
(shift_t, shift_n) = (SRTYPE_LSL, 0);
```

T2

| | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|----|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 3 | 2 | 0 |
| 0 | 1 | 0 | 0 | 0 | 1 | 0 | 1 | N | Rm | Rn | | |

T2 variant

CMP{<c>}{<q>} <Rn>, <Rm> // <Rn> and <Rm> not both from R0-R7

Decode for this encoding

```
n = UInt(N:Rn); m = UInt(Rm);
(shift_t, shift_n) = (SRTYPE_LSL, 0);
if n < 8 && m < 8 then UNPREDICTABLE;
if n == 15 || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n < 8$ && $m < 8$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The condition flags become UNKNOWN.

T3

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|------|----|----|----|----|------|------|----|---|---|---|---|---|

Rotate right with extend variant

Applies when $imm3 == 000$ && $imm2 == 00$ && $type == 11$.

CMP{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when $!(imm3 == 000$ && $imm2 == 00$ && $type == 11)$.

CMP{<c>}.W <Rn>, <Rm> // <Rn>, <Rm> can be represented in T1 or T2
 CMP{<c>}{<q>} <Rn>, <Rm>, <shift> #<amount>

Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
 For encoding T1 and T3: is the first general-purpose source register, encoded in the "Rn" field.
 For encoding T2: is the first general-purpose source register, encoded in the "N:Rn" field.
- <Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
 For encoding T1, T2 and T3: is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 LSL when type = 00

LSR when type = 01
ASR when type = 10
ROR when type = 11

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(R[n], NOT(shifted), '1');
    PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.37 CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

CMP{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
  (result, nzc) = AddWithCarry(R[n], NOT(shifted), '1');
  PSTATE.<N,Z,C,V> = nzc;
```

F5.1.38 CPS, CPSID, CPSIE

Change PE State changes one or more of the `PSTATE.{A, I, F}` interrupt mask bits and, optionally, the `PSTATE.M` mode field, without changing any other `PSTATE` bits.

CPS is treated as NOP if executed in User mode unless it is defined as being `CONSTRAINED UNPREDICTABLE` elsewhere in this section.

The PE checks whether the value being written to `PSTATE.M` is legal. See *Illegal changes to PSTATE.M* on page G1-3809.

A1

CPS variant

Applies when `imod == 00 && M == 1`.

`CPS{<q>} #<mode> // Cannot be conditional`

CPSID variant

Applies when `imod == 11 && M == 0`.

`CPSID{<q>} <iflags> // Cannot be conditional`

CPSID variant

Applies when `imod == 11 && M == 1`.

`CPSID{<q>} <iflags> , #<mode> // Cannot be conditional`

CPSIE variant

Applies when `imod == 10 && M == 0`.

`CPSIE{<q>} <iflags> // Cannot be conditional`

CPSIE variant

Applies when `imod == 10 && M == 1`.

`CPSIE{<q>} <iflags> , #<mode> // Cannot be conditional`

Decode for all variants of this encoding

```

if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10'); disable = (imod == '11'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If `imod == '01'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `imod == '00' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `changemode = TRUE`.
- The instruction executes as described, and the value specified by `mode` is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if `A:I:F` has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if `A:I:F == '000'`.

Decode for all variants of this encoding

```

if imod == '00' && M == '0' then SEE "Hint instructions";
if mode != '00000' && M == '0' then UNPREDICTABLE;
if (imod<1> == '1' && A:I:F == '000') || (imod<1> == '0' && A:I:F != '000') then UNPREDICTABLE;
enable = (imod == '10'); disable = (imod == '11'); changemode = (M == '1');
affectA = (A == '1'); affectI = (I == '1'); affectF = (F == '1');
if imod == '01' || InITBlock() then UNPREDICTABLE;

```

CONSTRAINED UNPREDICTABLE behavior

If imod == '01', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode != '00000' && M == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction executes with the additional decode: changemode = TRUE.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if `A:I:F` has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if `A:I:F == '000'`.

Notes for all encodings

Hint instructions: In encoding T2, if the `imod` field is `00` and the `M` bit is `0`, a hint instruction is encoded. To determine which hint instruction, see [Branches and miscellaneous control on page F3-2471](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

`<q>` See [Standard assembler syntax fields on page F2-2406](#).

`<iflags>` Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

| | |
|----------------|---|
| <code>a</code> | Sets the A bit in the instruction, causing the specified effect on <code>PSTATE.A</code> , the SError interrupt mask bit. |
| <code>i</code> | Sets the I bit in the instruction, causing the specified effect on <code>PSTATE.I</code> , the IRQ interrupt mask bit. |
| <code>f</code> | Sets the F bit in the instruction, causing the specified effect on <code>PSTATE.F</code> , the FIQ interrupt mask bit. |

`<mode>` Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0';
            if affectI then PSTATE.I = '0';
            if affectF then PSTATE.F = '0';
        if disable then
            if affectA then PSTATE.A = '1';
            if affectI then PSTATE.I = '1';
            if affectF then PSTATE.F = '1';
```

```
    if changemode then
        // AArch32.WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
        AArch32.WriteModeByInstr(mode);
else
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0';
            if affectI then PSTATE.I = '0';
            if affectF then PSTATE.F = '0';
        if disable then
            if affectA then PSTATE.A = '1';
            if affectI then PSTATE.I = '1';
            if affectF then PSTATE.F = '1';
        if changemode then
            // AArch32.WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
            AArch32.WriteModeByInstr(mode);
```

F5.1.39 CRC32

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In ARMv8-A, this is an OPTIONAL instruction.

———— **Note** ————

[ID_ISAR5](#).CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

A1

CRC32B variant

Applies when `sz == 00`.

CRC32B{<q>} <Rd>, <Rn>, <Rm>

CRC32H variant

Applies when `sz == 01`.

CRC32H{<q>} <Rd>, <Rn>, <Rm>

CRC32W variant

Applies when `sz == 10`.

CRC32W{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `size = 32`.

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | |

C

CRC32B variant

Applies when `sz == 00`.

CRC32B{<q>} <Rd>, <Rn>, <Rm>

CRC32H variant

Applies when `sz == 01`.

CRC32H{<q>} <Rd>, <Rn>, <Rm>

CRC32W variant

Applies when `sz == 10`.

CRC32W{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `size = 32;`.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#). An CRC32 instruction must be unconditional.
- <Rd> Is the general-purpose accumulator output register, encoded in the "Rd" field.
- <Rn> Is the general-purpose accumulator input register, encoded in the "Rn" field.
- <Rm> Is the general-purpose data source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();

    acc = R[n];           // accumulator
    val = R[m]<size-1:0>; // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

F5.1.40 CRC32C

CRC32C performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In ARMv8-A, this is an OPTIONAL instruction.

———— Note ————

[ID_ISAR5](#).CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|----|-----|---|---|---|---|----|---|---|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |

| cond | | | | | | | | | | C | | | | | | | | | | | | | | |

CRC32CB variant

Applies when `sz == 00`.

CRC32CB{<q>} <Rd>, <Rn>, <Rm>

CRC32CH variant

Applies when `sz == 01`.

CRC32CH{<q>} <Rd>, <Rn>, <Rm>

CRC32CW variant

Applies when `sz == 10`.

CRC32CW{<q>} <Rd>, <Rn>, <Rm>

Decode for all variants of this encoding

```

if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;

```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `size = 32`;

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

CRC32CB variant

Applies when `sz == 00`.

`CRC32CB{<q>} <Rd>, <Rn>, <Rm>`

CRC32CH variant

Applies when `sz == 01`.

`CRC32CH{<q>} <Rd>, <Rn>, <Rm>`

CRC32CW variant

Applies when `sz == 10`.

`CRC32CW{<q>} <Rd>, <Rn>, <Rm>`

Decode for all variants of this encoding

```

if ! HaveCRCExt() then UNDEFINED;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
size = 8 << UInt(sz);
crc32c = (C == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `size = 32;`.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#). An CRC32C instruction must be unconditional.
- <Rd> Is the general-purpose accumulator output register, encoded in the "Rd" field.
- <Rn> Is the general-purpose accumulator input register, encoded in the "Rn" field.
- <Rm> Is the general-purpose data source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();

    acc = R[n];           // accumulator
    val = R[m]<size-1:0>; // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

F5.1.41 DBG

In ARMv8, DBG executes as a NOP. ARM deprecates any use of the DBG instruction.

A1

T1 variant

DBG{<c>}{<q>} #<option>

Decode for this encoding

// DBG executes as a NOP. The 'option' field is ignored

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<option> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "option" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
```

F5.1.42 DCPS1, DCPS2, DCPS3

DCPSx, Debug Change PE State to ELx, where x is 1, 2, or 3.

When executed in Debug state, the target Exception level of the instruction is:

- ELx, if the instruction is executed at an Exception level lower than ELx.
- Otherwise, the Exception level at which the instruction is executed.

On executing a DCPSx instruction in Debug state when the instruction is not UNDEFINED:

- If the instruction is executed at an Exception level that is lower than the target Exception level the PE enters the target Exception level, Elx, and:
 - If ELx is using AArch64, the PE selects SP_ELx.
 - If the target Exception level is EL1 using AArch32 the PE enters Supervisor mode.
 - If the instruction was executed in Non-secure state and the target Exception level is EL2 using AArch32 the PE enters Hyp mode.
 - If the target Exception level is EL3 using AArch32 the PE enters Supervisor mode and SCR.NS is set to 0.
- Otherwise, there is no change to the Exception level and:
 - If the instruction was executed at EL1 the PE enters Supervisor mode.
 - If the instruction was executed at EL2 the PE remains in Hyp mode.
 - If the instruction was a DCPS1 instruction executed at EL3 the PE enters Supervisor mode and SCR.NS is set to 0.
 - If the instruction was a DCPS3 instruction executed at EL3 the PE enters Monitor mode and SCR.NS is set to 0.

These instructions are always UNDEFINED in Non-debug state.

DCPS1 is UNDEFINED at EL0 in Non-secure state if either:

- EL2 is implemented and using AArch64 and HCR_EL2.TGE == 1.
- EL2 is implemented and using AArch32 and HCR.TGE == 1.

DCPS2 is UNDEFINED at all Exception levels if EL2 is not implemented.

DCPS2 is UNDEFINED in the following states if EL2 is implemented:

- At EL0 and EL1 in Secure state.
- At EL3 if EL3 is using AArch32.

DCPS3 is UNDEFINED at all Exception levels if either:

- EDSCR.SDD == 1.
- EL3 is not implemented.

On executing a DCPSx instruction that is not UNDEFINED and targets ELx:

- If ELx is using AArch64:
 - ELR_ELx, SPSR_ELx, and ESR_ELx become UNKNOWN.
 - DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- If ELx is using AArch32 DLR and DSPSR become UNKNOWN and:
 - If the target Exception level is EL1 or EL3, the LR and SPSR of the target PE mode become UNKNOWN.
 - If the target Exception level is EL2, then ELR_hyp, SPSR_hyp, and HSR become UNKNOWN.

For more information on the operation of these instructions, see [DCPS<n>](#) on page H2-4870.

T1

DataSynchronizationBarrier(domain, types);
```

F5.1.45 EOR, EORS (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

EOR variant

Applies when `S == 0`.

`EOR{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

EORS variant

Applies when `S == 1 && Rd != 1111`.

EORS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE TEQ (immediate);
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:
 - For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
 - For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  result = R[n] EOR imm32;
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
  else
    R[d] = result;
    if setflags then
      PSTATE.N = result<31>;
      PSTATE.Z = IsZeroBit(result);
      PSTATE.C = carry;
      // PSTATE.V unchanged
```

F5.1.46 EOR, EORS (register)

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 3 | 2 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | Rm | Rdn | | |

T1 variant

EOR<c>{<q>} {<Rdn>}, <Rdn>, <Rm> // Inside IT block
 EORS{<q>} {<Rdn>}, <Rdn>, <Rm> // Outside IT block

Decode for this encoding

```
d = UInt(Rdn); n = UInt(Rdn); m = UInt(Rm); setflags = !InITBlock();
(shift_t, shift_n) = (SRTYPE_LSL, 0);
```

T2

| | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|------|----|------|------|----|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | S | Rn | (0) | imm3 | Rd | imm2 | type | Rm | | | | | | |

EOR, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && type == 11.

EOR{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

EOR, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && type == 11).

EOR<c>.W {<Rd>}, <Rn>, <Rm> // Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
 EOR{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

EORS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && type == 11.

EORS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

EORS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && type == 11) && Rd != 1111.

EORS.W {<Rd>}, <Rn>, <Rm> // Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1
 EORS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE TEQ (register);
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | | | | | |
|----------|---|-----|----------------|-----|----------------|-----|----------------|-----|----------------|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rdn> | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field. | | | | | | | | |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none"> For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. <p>For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.</p> | | | | | | | | |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else

```

```
        ALUwritePC(result);  
else  
    R[d] = result;  
    if setflags then  
        PSTATE.N = result<31>;  
        PSTATE.Z = IsZeroBit(result);  
        PSTATE.C = carry;  
        // PSTATE.V unchanged
```

F5.1.47 EOR, EORS (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

| | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|---------|----|----|----|---------|----|----|----|----|----|----|---|----|---|--------|---|------|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| !=1111 | | | | 0 0 0 0 | | | | 0 0 1 S | | | | Rn | | Rd | | Rs | | 0 type | | 1 Rm | |
| cond | | | | | | | | | | | | | | | | | | | | | |

Flag setting variant

Applies when S == 1.

EORS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

EOR{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | | | | | |

| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. | | | | | | | | |
| <Rn> | Is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | Is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <type> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table style="margin-left: 20px;"> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. | | | | | | | | |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.48 ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores [PSTATE](#) from `SPSR_<current_mode>`.

The register holding the preferred return address is:

- `ELR_hyp`, when executing in Hyp mode.
- `LR`, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state on page G1-3835*.

Exception Return is **CONSTRAINED UNPREDICTABLE** in User mode and System mode.

In Debug state, the T1 encoding of ERET executes the DRPS operation.

ERET{<c>}{<q>}

Decode for this encoding

if `InITBlock()` && `!LastInITBlock()` then **UNPREDICTABLE**;

Notes for all encodings

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See *Standard assembler syntax fields on page F2-2406*.

<q> See *Standard assembler syntax fields on page F2-2406*.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
if PSTATE.M IN {M32_User, M32_System} then
    UNPREDICTABLE; // UNDEFINED or NOP
else
    new_pc_value = if PSTATE.EL == EL2 then ELR_hyp else R[14];
    AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.49 HLT

Halting breakpoint causes a software breakpoint to occur.

Halting breakpoint is always unconditional, even inside an IT block.

A1

| | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|-------|--|--|--|--|---|---------|---|---|---|------|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | | | | | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

| cond | | | | | | | | | | | | | | | | | | | | | |

A1 variant

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
if cond != '1110' then UNPREDICTABLE; // HLT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

| | | | | | | | | | | | | | | | | | | | | | |
|---------------------|----|----|----|----|----|---|---|---|---|------|--|--|--|--|--|--|--|--|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | | | | | | | | | | | 0 |
| 1 0 1 1 1 0 1 0 1 0 | | | | | | | | | | imm6 | | | | | | | | | | | |

T1 variant

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<q> See [Standard assembler syntax fields on page F2-2406](#). An HLT instruction must be unconditional.

<imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

For encoding T1: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation for all encodings

```
EncodingSpecificOperations();  
Halt(DebugHalt_HaltInstruction);
```

F5.1.50 HVC

Hypervisor Call causes a Hypervisor Call exception. For more information see [Hypervisor Call \(HVC\) exception on page G1-3855](#). Non-secure software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is:

- UNDEFINED in Secure state, and in User mode in Non-secure state.
- When `SCR.HCE` is set to 0, UNDEFINED in Non-secure EL1 modes and CONSTRAINED UNPREDICTABLE in Hyp mode.

On executing an HVC instruction, the `HSR` reports the exception as a Hypervisor Call exception, using the EC value `0x12`, and captures the value of the immediate argument, see [Use of the HSR on page G4-4137](#).

A1

| | | | | | | | | | | | | | | | | | | | | | | |

T1 variant

HVC{<q>} {#}<imm16>

Decode for this encoding

```
imm16 = imm4:imm12;
if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#). An HVC instruction must be unconditional.
- <imm16> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.
- For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

Operation for all encodings

```
EncodingSpecificOperations();
if !HaveEL(EL2) || PSTATE.EL == EL0 || IsSecure() then
    UNDEFINED;

if HaveEL(EL3) then
    if ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2 then
        UNPREDICTABLE;
    else
        hvc_enable = SCR_GEN[].HCE;
else
    hvc_enable = if ELUsingAArch32(EL3) then NOT(HCR_EL2.HCD) else NOT(HCR.HCD);

if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```

CONSTRAINED UNPREDICTABLE behavior

If ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.51 ISB

Instruction Synchronization Barrier flushes the pipeline in the PE, so that all instructions following the ISB are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the ISB instruction are visible to the instructions fetched after the ISB. Context changing operations include changing the Address Space Identifier (ASID), TLB maintenance instructions, branch predictor maintenance operations, and all changes to the System registers.

In addition, any branches that appear in program order after the ISB instruction are written into the branch prediction logic with the context that is visible after the ISB instruction. This is needed to ensure correct execution of the instruction stream.

For more information, see [Instruction Synchronization Barrier \(ISB\) on page E2-2335](#).

Decode for this encoding

// No additional decoding required

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). Must be AL or omitted.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <option> Specifies an optional limitation on the barrier operation. Values are:
 - SY Full system barrier operation, encoded as option = 0b1111. Can be omitted.
 All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    InstructionSynchronizationBarrier();
```

F5.1.52 IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

Many uses of the IT instruction are deprecated for performance reasons, and an implementation might include ITD controls that can disable those uses of IT, making them UNDEFINED. For more information see [Conditional execution on page F2-2407](#).

See also [Conditional instructions on page F1-2369](#) and [Conditional execution on page F2-2407](#).

T1

| | | | | | | | | | | | |
|------|----|----|----|----|----|---|---|-----------|--------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 4 | 3 | 0 |
| 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | firstcond | !=0000 | | |
| mask | | | | | | | | | | | |

T1 variant

IT{<x>{<y>{<z>}}}{<q> <cond>

Decode for this encoding

```
if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If firstcond == '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: firstcond = '1110'.

If firstcond == '1110' && BitCount(mask) != 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Miscellaneous 16-bit instructions on page F3-2442](#).

Assembler symbols

- <x> The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000. If present it is encoded in the "mask[3]" field:
- | | |
|---|------------------|
| T | firstcond[0] |
| E | NOT firstcond[0] |
- <y> The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]" field is set to 0b100. If <y> is present it is encoded in the "mask[2]" field:
- | | |
|---|------------------|
| T | firstcond[0] |
| E | NOT firstcond[0] |
- <z> The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]" field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]" field:
- | | |
|---|------------------|
| T | firstcond[0] |
| E | NOT firstcond[0] |
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <cond> The condition for the first instruction in the IT block, encoded in the "firstcond" field. See [Table F2-1 on page F2-2407](#) for the range of conditions available, and the encodings.

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See [Conditional instructions on page F1-2369](#).

Operation

```
EncodingSpecificOperations();  
AArch32.CheckITEnabled(mask);  
PSTATE.IT<7:0> = firstcond:mask;
```

LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

t = UInt(Rt); t2 = t + 1; n = UInt(Rn);
 if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt == '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

```

F5.1.60 LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the **DBGDTRXint** System register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

In an implementation that includes EL2, the permitted LDC access to **DBGDTRXint** can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [Trapping general Non-secure System register accesses to debug registers on page G1-3911](#).

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

A1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 1$.

LDC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

LDC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Unindexed variant

Applies when $P == 0 \ \&\& \ U == 1 \ \&\& \ W == 0$.

LDC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDC (literal);
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn); cp = 14;
imm32 = ZeroExtend(imm8:'00', 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
```

T1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

LDC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Unindexed variant

Applies when P == 0 && U == 1 && W == 0.

LDC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```
if Rn == '1111' then SEE LDC (literal);
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn); cp = 14;
imm32 = ZeroExtend(imm8:'00', 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
```

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see [LDC \(literal\)](#).
- <option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- <imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  AArch32.CheckSystemAccess(cp, ThisInstr());
  offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
  address = if index then offset_addr else R[n];

  // System register write to DBGDTRXint.
  DBGDTR_EL0[] = MemA[address,4];

  if wback then R[n] = offset_addr;
```

F5.1.61 LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the **DBGDTRXint** System register. For information about memory accesses see *Memory accesses* on page F2-2412.

In an implementation that includes EL2, the permitted LDC access to **DBGDTRXint** can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers* on page G1-3911.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|------|--|--|--|--|--|--|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | | | | | | 0 |
| !=1111 | | 1 | 1 | 0 | P | U | 0 | W | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 1 | 1 | 0 | imm8 | | | | | | | |
| cond | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

Applies when $!(P == 0 \ \&\& \ U == 0 \ \&\& \ W == 0)$.

```
LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #+/-<imm>]
LDC{<c>}{<q>} p14, c5, [PC], <option>
```

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1'); add = (U == '1'); cp = 14; imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|---|---|------|--|--|--|--|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | | | | | | 0 |

T1 variant

Applies when $!(P == 0 \ \&\& \ U == 0 \ \&\& \ W == 0)$.

```
LDC{<c>}{<q>} p14, c5, <label>
LDC{<c>}{<q>} p14, c5, [PC, #+/-<imm>]
```

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;  
index = (P == '1'); add = (U == '1'); cp = 14; imm32 = ZeroExtend(imm8:'00', 32);  
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $W == '1' || P == '0'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes as LDC (immediate) with writeback to the PC. The instruction is handled as described in [Using R15 on page K1-5457](#).

Assembler symbols

| | |
|----------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <option> | Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction. |
| <label> | The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <code>Align(PC, 4)</code> value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, <code>imm32</code> is equal to the offset and <code>add == TRUE</code> (encoded as <code>U == 1</code>). If the offset is negative, <code>imm32</code> is equal to minus the offset and <code>add == FALSE</code> (encoded as <code>U == 0</code>). |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when <code>U = 0</code> + when <code>U = 1</code> |
| <imm> | Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <code><imm>/4</code> . |

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  AArch32.CheckSystemAccess(cp, ThisInstr());  
  offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);  
  address = if index then offset_addr else Align(PC,4);  
  
  // System register write to DBGDTRXint.  
  DBGDTR_EL0[] = MemA[address,4];
```

F5.1.62 LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

This instruction is used by the alias [POP \(multiple registers\)](#). See [Alias conditions on page F5-2701](#) for details of when each alias is preferred.

A1

A1 variant

LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $\text{BitCount}(\text{registers}) < 1$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = '00000000':register_list; wback = (registers<n> == '0');
if BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T2

T2 variant

LDM{IA}{<c>}.W <Rn>{!}, <registers> // Preferred syntax, if <Rn>, '!' and <registers> can be represented in T1
 LDMFD{<c>}.W <Rn>{!}, <registers> // Alternate syntax, Full Descending stack, if <Rn>, '!' and <registers> can be represented in T1
 LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 LDMFD{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = P:M:register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|--|------------|---|
| POP (multiple registers) | T2 | <code>W == '1' && Rn == '1101' && BitCount(P:M:register_list) > 1</code> |
| POP (multiple registers) | A1 | <code>W == '1' && Rn == '1101' && BitCount(register_list) > 1</code> |

Assembler symbols

| | |
|------|--|
| IA | Is an optional suffix for the Increment After form. |
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| ! | For encoding A1 and T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0. |

For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers> For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. ARM deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field.

For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F5.1.63 LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The **SPSR** of the current mode is copied to the **CPSR**. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

Load Multiple (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in debug state, and in User mode and System mode.

A1

A1 variant

LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^

Decode for this encoding

```
n = UInt(Rn); registers = register_list;
wback = (W == '1'); increment = (U == '1'); wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | |
|----------------------|------------|--|
| <amode> | is one of: | |
| | DA | Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0. |
| | FA | Full Ascending. For this instruction, a synonym for DA. |
| | DB | Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0. |
| | EA | Empty Ascending. For this instruction, a synonym for DB. |

| | |
|----|--|
| IA | Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1. |
| FD | Full Descending. For this instruction, a synonym for IA. |
| IB | Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1. |
| ED | Empty Descending. For this instruction, a synonym for IB. |

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers_with_pc> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

Instructions with similar syntax but without the PC included in the registers list are described in [LDM \(User registers\)](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elseif PSTATE.M IN {M32_User, M32_System} then
        UNPREDICTABLE; // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;

        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemA[address,4]; address = address + 4;
        new_pc_value = MemA[address,4];

        if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
  
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.64 LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

A1

A1 variant

LDM{<amode>}{<c>}{<q>} <Rn>, <registers_without_pc>^

Decode for this encoding

```
n = UInt(Rn); registers = register_list; increment = (U == '1'); wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | |
|---------|------------|--|
| <amode> | is one of: | |
| | DA | Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0. |
| | FA | Full Ascending. For this instruction, a synonym for DA. |
| | DB | Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0. |
| | EA | Empty Ascending. For this instruction, a synonym for DB. |
| | IA | Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1. |
| | FD | Full Descending. For this instruction, a synonym for IA. |
| | IB | Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1. |
| | ED | Empty Descending. For this instruction, a synonym for IB. |

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<registers_without_pc>

Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in [LDM \(exception return\)](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UNDEFINED;
    elseif PSTATE.M IN {M32_User,M32_System} then UNPREDICTABLE;
    else
        length = 4*BitCount(registers);
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then // Load User mode register
                Rmode[i, M32_User] = MemA[address,4]; address = address + 4;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

F5.1.65 LDMDA, LDMFA

Load Multiple Decrement After (Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

A1

| | | | | | | | | | | | | | |
|----|-------|----|----|-------|----|----|-------|-------|---|--|----|---|---------------|
| 31 | 28 27 | 26 | 25 | 24 23 | 22 | 21 | 20 19 | 16 15 | | | | 0 | |
| | =1111 | | 1 | 0 | 0 | 0 | 0 | W | 1 | | Rn | | register_list |
| | cond | | | | | | | | | | | | |

A1 variant

```
LMDMA{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
LDMFA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Ascending stack
```

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. ARM deprecates using these instructions with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F5.1.66 LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

A1

A1 variant

LDMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 LDMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T1

T1 variant

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax  
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack
```

Decode for this encoding

```
n = UInt(Rn); registers = P:M:register_list; wback = (W == '1');  
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;  
if wback && registers<n> == '1' then UNPREDICTABLE;  
if registers<13> == '1' then UNPREDICTABLE;  
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. ARM deprecates using these instructions with both the LR and the PC in the list.
- For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list:
- The LR must not be in the list.
 - The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F5.1.67 LDMIB, LDMED

Load Multiple Increment Before (Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

A1

A1 variant

LDMIB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 LDMED{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If wback && registers<n> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. ARM deprecates using these instructions with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4]; address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

F5.1.68 LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2412.

This instruction is used by the alias [POP \(single register\)](#). See [Alias conditions](#) on page F5-2716 for details of when each alias is preferred.

A1

Offset variant

Applies when $P == 1$ && $W == 0$.

LDR{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when $P == 0$ && $W == 0$.

LDR{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

LDR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDR (literal);
if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if wback && n == t then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $wback$ && $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDR{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5:'00', 32);
 index = TRUE; add = TRUE; wback = FALSE;

T2

| | | | | | | | | | | | |

| 15 | 14 | 13 | 12 | 11 | 10 | 8 | 7 | | | | 0 |
| 1 | 0 | 0 | 1 | 1 | Rt | | imm8 | | | | |

T2 variant

LDR{<c>}{<q>} <Rt>, [SP{, #<+><imm>}]

Decode for this encoding

t = UInt(Rt); n = 13; imm32 = ZeroExtend(imm8:'00', 32);
 index = TRUE; add = TRUE; wback = FALSE;

T3

| | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|--------|---|----|----|-------|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | | | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | !=1111 | | Rt | | imm12 | | | |

Rn

T3 variant

LDR{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // <Rt>, <Rn>, <imm> can be represented in T1 or T2
 LDR{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

if Rn == '1111' then SEE LDR (literal);
 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32); index = TRUE; add = TRUE;
 wback = FALSE; if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

T4

| | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|--------|---|----|----|----|----|---|---|------|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | | | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | !=1111 | | Rt | | 1 | P | U | W | imm8 | | | |

Rn

Offset variant

Applies when P == 1 && U == 0 && W == 0.

LDR{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

LDR{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then SEE LDR (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn);
imm32 = ZeroExtend(imm8, 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|---------------------------------------|-------------------|--|
| POP (single register) | A1 (post-indexed) | P == '0' && U == '1' && W == '0' && Rn == '1101' && imm12 == '00000000100' |
| POP (single register) | T4 (post-indexed) | Rn == '1101' && U == '1' && imm8 == '00000100' |

Assembler symbols

| | |
|------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293 . For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field. For encoding T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293 . |
| <Rn> | For encoding A1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal) . For encoding T1: is the general-purpose base register, encoded in the "Rn" field. |

- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the offset is added to the base register.
- <imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
 For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.
 For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.
 For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
 For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
      if address<1:0> == '00' then
        LoadWritePC(data);
      else
        UNPREDICTABLE;
    else
      R[t] = data;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
      if address<1:0> == '00' then
        LoadWritePC(data);
      else
        UNPREDICTABLE;
    else
      R[t] = data;
  
```

F5.1.69 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

A1 variant

Applies when !(P == 0 && W == 1).

LDR{<c>}{<q>} <Rt>, <label> // Normal form
 LDR{<c>}{<q>} <Rt>, [PC, #+/-<imm>] // Alternative form

Decode for this encoding

```
if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDR \(immediate\)](#). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#) on page K1-5457.

T1

T1 variant

LDR{<c>}{<q>} <Rt>, <label> // Normal form

Decode for this encoding

```
t = UInt(Rt); imm32 = ZeroExtend(imm8:'00', 32); add = TRUE;
```

T2

T2 variant

```
LDR{<c>}.W <Rt>, <label> // Preferred syntax, and <Rt>, <label> can be represented in T1
LDR{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDR{<c>}{<q>} <Rt>, [PC, #<+/-><imm>] // Alternative syntax
```

Decode for this encoding

```
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

If the offset is negative, <code>imm32</code> is equal to minus the offset and <code>add == FALSE</code>, encoded as <code>U == 0</code>.</p> <p>For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the <code>Align(PC, 4)</code> value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.</p> |
| <+/-> | <p>Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:</p> <ul style="list-style-type: none"> - when U = 0 + when U = 1 |
| <imm> | <p>For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.</p> <p>For encoding T2: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.</p> |

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

F5.1.70 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see [Memory accesses](#) on page F2-2412.

The T32 form of LDR (register) does not support register writeback.

A1

Offset variant

Applies when P == 1 && W == 0.

LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}]

Pre-indexed variant

Applies when P == 1 && W == 1.

LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = (SRTYPE_LSL, 0);

T2

T2 variant

LDR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
 LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

if Rn == '1111' then SEE LDR (literal);
 t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = (SRTYPE_LSL, UInt(imm2));
 if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
 if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
 For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.
 For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
 For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1

- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register on page F2-2410](#).
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
      if address<1:0> == '00' then
        LoadWritePC(data);
      else
        UNPREDICTABLE;
    else
      R[t] = data;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = (R[n] + offset);
    address = offset_addr;
    data = MemU[address,4];
    if t == 15 then
      if address<1:0> == '00' then
        LoadWritePC(data);
      else
        UNPREDICTABLE;
    else
      R[t] = data;
```

F5.1.71 LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRB (literal);
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5, 32);
index = TRUE; add = TRUE; wback = FALSE;
```

T2

T2 variant

LDRB{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // <Rt>, <Rn>, <imm> can be represented in T1
 LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rt == '1111' then SEE PLD;
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = TRUE; add = TRUE; wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

T3

Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

LDRB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>!]

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLD, PLDW (immediate);
if Rn == '1111' then SEE LDRB (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRBT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|-------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRB (literal) . For encoding T1: is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field. For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field. |

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F5.1.72 LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

A1 variant

Applies when $!(P == 0 \ \&\& \ W == 1)$.

LDRB{<c>}{<q>} <Rt>, <label> // Normal form
 LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form

Decode for this encoding

```
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRB \(immediate\)](#). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

T1 variant

LDRB{<c>}{<q>} <Rt>, <label> // Preferred syntax
 LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax

Decode for this encoding

```
if Rt == '1111' then SEE PLD;
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when `U = 0`
 - + when `U = 1`
- <imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

F5.1.73 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

| | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|------|------|---|----|---|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 |

 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, 0);

T2

T2 variant

LDRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
 LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

if Rt == '1111' then SEE PLD;
 if Rn == '1111' then SEE LDRB (literal);
 t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, UInt(imm2));
 if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
 For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 + when U = 1
- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register on page F2-2410](#).
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

F5.1.74 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

A1 variant

LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/->{<imm>}}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15 on page K1-5457](#).
- The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

A2 variant

LDRBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm); postindex = TRUE; add = (U == '1');
register_form = TRUE; (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Rn

T1 variant

LDRBT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| +/- | For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:

- when U = 0
+ when U = 1

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register on page F2-2410](#).

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
  if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
  EncodingSpecificOperations();
  offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  R[t] = ZeroExtend(MemU_unpriv[address,1],32);
  if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRB (immediate).

F5.1.75 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

Offset variant

Applies when P == 1 && W == 0.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRD (literal);
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If P == '0' && W == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes with the additional decode: $t<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

T1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 1$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '0' then SEE "Related encodings";
if Rn == '1111' then SEE LDRD (literal);
t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

CONSTRAINED UNPREDICTABLE behavior

If $wback \ \&\& \ (n == t \ || \ n == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

Notes for all encodings

| <Rt2> | For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRD (literal) . |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4. |

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
    if wback then R[n] = offset_addr;
  
```

F5.1.76 LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

A1 variant

LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // Normal form
 LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #<+/-><imm>] // Alternative form

Decode for this encoding

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; imm32 = ZeroExtend(imm4H:imm4L, 32); add = (U == '1');
if t2 == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0';.
- The instruction executes with the additional decode: t2 = t;.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

If P == '0' || W == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as if P == 1 and W == 0.'

T1

T1 variant

Applies when !(P == 0 && W == 0).

LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // Normal form
 LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #<+/-><imm>] // Alternative form

Decode for this encoding

```
if P == '0' && W == '0' then SEE "Related encodings";  
t = UInt(Rt); t2 = UInt(Rt2);  
imm32 = ZeroExtend(imm8:'00', 32); add = (U == '1');  
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13  
if W == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

If $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses post-indexed addressing when $P == '0'$ and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15 on page K1-5457](#).

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/Store dual](#), [Load/Store Exclusive](#), [Load-Acquire/Store-Release](#), and [table branch on page F3-2466](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rt> For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

<Rt2> For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.

- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
 - + when U = 1
- <imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
- For encoding T1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
```

F5.1.77 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 0$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 || m == t || m == t2 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $wback \ \&\& \ (n == t \ || \ n == t2)$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If $P == '0' \ \&\& \ W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If $m == t \ || \ m == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction loads register Rm with an UNKNOWN value.
- If Rt<0> == '1', then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes with the additional decode: t<0> = '0'.
 - The instruction executes with the additional decode: t2 = t.
 - The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.
- <Rt2> Is the second general-purpose register to be transferred. This register must be <R(t+1)>.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
 - + when U = 1
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];

    if wback then R[n] = offset_addr;
  
```

F5.1.78 LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2355](#). For information about memory accesses see [Memory accesses on page F2-2412](#).

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,1);
    R[t] = ZeroExtend(MemA[address,1], 32);
```

F5.1.80 LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2355](#). For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
t = UInt(Rt); t2 = t + 1; n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If Rt<0> == '1', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If Rt == '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|----|-----|----|----|---|---|-----|-----|-----|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,2);
    R[t] = ZeroExtend(MemA[address,2], 32);
```

F5.1.82 LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

LDRH{<c>}{<q>} <Rt>, [<Rn> {, #+/-}<imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRH{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRH{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>!]

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRH (literal);
if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRH{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>}]

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE; add = TRUE; wback = FALSE;
```

T2

T2 variant

LDRH{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // <Rt>, <Rn>, <imm> can be represented in T1
 LDRH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rt == '1111' then SEE PLD (immediate);
if Rn == '1111' then SEE LDRH (literal);
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = TRUE; add = TRUE; wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

T3

Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

LDRH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>!]

Decode for all variants of this encoding

```
if Rn == '1111' then SEE LDRH (literal);
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLDW (immediate);
if P == '1' && U == '1' && W == '0' then SEE LDRHT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|-------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |

| cond | | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

Applies when $!(P == 0 \ \&\& \ W == 1)$.

```
LDRH{<c>}{<q>} <Rt>, <label> // Normal form
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative form
```

Decode for this encoding

```
if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt); imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRH \(immediate\)](#). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

| | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--------|-------|----|--|--|--|--|---|

T1 variant

```
LDRH{<c>}{<q>} <Rt>, <label> // Preferred syntax
LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // Alternative syntax
```

Decode for this encoding

```
if Rt == '1111' then SEE PLD (literal);
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when `U = 0`
 - + when `U = 1`
- <imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
- For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
```

F5.1.84 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 0$.

LDRH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE LDRHT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRTYPE_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $wback \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = TRUE; add = TRUE; wback = FALSE;
(shift_t, shift_n) = (SRTYPE_LSL, 0);
```

T2

T2 variant

LDRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
 LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

```
if Rn == '1111' then SEE LDRH (literal);
if Rt == '1111' then SEE PLDW (register);
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = TRUE; add = TRUE; wback = FALSE;
(shift_t, shift_n) = (SRTYPE_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
 For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
```

```
offset_addr = if add then (R[n] + offset) else (R[n] - offset);  
address = if index then offset_addr else R[n];  
data = MemU[address,2];  
if wback then R[n] = offset_addr;  
R[t] = ZeroExtend(data, 32);
```

F5.1.85 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

| cond | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

LDRHT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/->{<imm>}}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15 on page K1-5457](#).
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t \ \&\& \ n \neq 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

| | |
|-------|--|
| +/- | For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <Rm> | Is the general-purpose index register, encoded in the "Rm" field. |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRH (immediate).

F5.1.86 LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRSB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRSB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRSB (literal);
if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rt == '1111' then SEE PLI;

t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = TRUE; add = TRUE; wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
```

T2

Offset variant

Applies when P == 1 && U == 0 && W == 0.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]
```

Post-indexed variant

Applies when P == 0 && W == 1.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed variant

Applies when P == 1 && W == 1.

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLI;
if Rn == '1111' then SEE LDRSB (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRSBT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

| | |
|-------|--|
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRSB (literal) . |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

F5.1.87 LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

A1 variant

Applies when $!(P == 0 \ \&\& \ W == 1)$.

LDRSB{<c>}{<q>} <Rt>, <label> // Normal form
 LDRSB{<c>}{<q>} <Rt>, [PC, #+/-<imm>] // Alternative form

Decode for this encoding

```
if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt); imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRSB \(immediate\)](#). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#) on page K1-5457.

T1

T1 variant

LDRSB{<c>}{<q>} <Rt>, <label> // Preferred syntax
 LDRSB{<c>}{<q>} <Rt>, [PC, #+/-<imm>] // Alternative syntax

Decode for this encoding

```
if Rt == '1111' then SEE PLI;
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when `U = 0`
 - + when `U = 1`
- <imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
- For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC, 4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address, 1], 32);
```

F5.1.88 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRSB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE LDRSBT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRTYPE_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
 For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
```

```
offset_addr = if add then (R[n] + offset) else (R[n] - offset);  
address = if index then offset_addr else R[n];  
R[t] = SignExtend(MemU[address,1], 32);  
if wback then R[n] = offset_addr;
```

F5.1.89 LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|---|---|---|---|-------|---|---|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |
| !=1111 | | | | 0 | 0 | 0 | 0 | U | 1 | 1 | 1 | Rn | Rt | imm4H | 1 | 1 | 0 | 1 | imm4L | | | |

A1 variant

LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15 on page K1-5457](#).
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

A2 variant

LDRSBT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm); postindex = TRUE; add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRSBT{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>}]

Decode for this encoding

Operation for all encodings

```
if ConditionPassed() then
  if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
  EncodingSpecificOperations();
  offset = if register_form then R[m] else imm32;
  offset_addr = if add then (R[n] + offset) else (R[n] - offset);
  address = if postindex then R[n] else offset_addr;
  R[t] = SignExtend(MemU_unpriv[address,1], 32);
  if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRSB (immediate).

F5.1.90 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

LDRSH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRSH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRSH (literal);
if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```

if Rn == '1111' then SEE LDRSH (literal);
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = TRUE; add = TRUE; wback = FALSE;
// ARMv8-A removes UNPREDICTABLE for R13
  
```

T2

Offset variant

Applies when Rt != 1111 && P == 1 && U == 0 && W == 0.

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

LDRSH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

LDRSH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

Decode for all variants of this encoding

```

if Rn == '1111' then SEE LDRSH (literal);
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE "Related instructions";
if P == '1' && U == '1' && W == '0' then SEE LDRSHT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
  
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRSH (literal) . |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU(address,2);
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

F5.1.91 LDRSH (literal)

Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

A1 variant

Applies when $!(P == 0 \ \&\& \ W == 1)$.

LDRSH{<c>}{<q>} <Rt>, <label> // Normal form
 LDRSH{<c>}{<q>} <Rt>, [PC, #+/-<imm>] // Alternative form

Decode for this encoding

```
if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt); imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRSH \(immediate\)](#). The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

T1 variant

LDRSH{<c>}{<q>} <Rt>, <label> // Preferred syntax
 LDRSH{<c>}{<q>} <Rt>, [PC, #+/-<imm>] // Alternative syntax

Decode for this encoding

```
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt); imm32 = ZeroExtend(imm12, 32); add = (U == '1');
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related instructions: [Load literal on page F3-2489](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as `U == 1`. If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as `U == 0`.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when `U = 0`
 - + when `U = 1`
- <imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
- For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = SignExtend(data, 32);
```

F5.1.92 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 0$.

LDRSH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE LDRSHT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRTYPE_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If $wback \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is <arm-defined-word>unknown</arm-defined-word>. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, 0);

T2

T2 variant

LDRSH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
 LDRSH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

if Rn == '1111' then SEE LDRSH (literal);
 if Rt == '1111' then SEE "Related instructions";
 t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, UInt(imm2));
 if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
 For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

F5.1.93 LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

A1 variant

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15 on page K1-5457](#).
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If n == t && n != 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRSH (immediate).

F5.1.94 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

A1 variant

LDRT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15 on page K1-5457](#).
- The instruction is treated as if $\text{bit}[24] == '1'$ and $\text{bit}[21] == '0'$. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

A2 variant

LDRT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm); postindex = TRUE; add = (U == '1');
register_form = TRUE; (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$ && $n != 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

T1 variant

LDRT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).

    data = MemU_unpriv[address,4];
    if postindex then R[n] = offset_addr;
    R[t] = data;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDR (immediate).

F5.1.95 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This instruction is an alias of the [MOV, MOVS \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

T2

Flag setting variant

LSRS.W {<Rd>}, <Rm>, <Rs> // Outside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>

and is always the preferred disassembly.

LSRS{<c>}{<q>} {<Rd> , } <Rm> , <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd> , <Rm> , LSR <Rs>

and is always the preferred disassembly.

Assembler symbols

| | |
|-------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rdm> | Is the first general-purpose source register and the destination register, encoded in the "Rdm" field. |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the first general-purpose source register, encoded in the "Rm" field. |
| <Rs> | Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. |

Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

F5.1.103 MCR

Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface on page E1-2312](#) and [General behavior of System registers on page G4-4151](#).

In an implementation that includes EL2, MCR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable controls on page G1-3894](#).

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

A1

A1 variant

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

t = UInt(Rt); cp = if coproc<0> == '0' then 14 else 15;
 if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

T1

T1 variant

MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

t = UInt(Rt); cp = if coproc<0> == '0' then 14 else 15;
 if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

- <coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:
- p14 when coproc<0> = 0
 - p15 when coproc<0> = 1
- <opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc1" field.
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.
- <CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.
- <opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc2" field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    AArch32.SysRegWrite(cp, ThisInstr(), R[t]);
```

F5.1.104 MCRR

Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface on page E1-2312](#) and [General behavior of System registers on page G4-4151](#).

In an implementation that includes EL2, MCRR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable controls on page G1-3894](#).

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

A1

A1 variant

MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
t = UInt(Rt); t2 = UInt(Rt2); cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

T1

T1 variant

MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
t = UInt(Rt); t2 = UInt(Rt2); cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:
- p14 when coproc<0> = 0
 - p15 when coproc<0> = 1
- <opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.
- <Rt> Is the first general-purpose register that is transferred into, encoded in the "Rt" field.
- <Rt2> Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.
- <CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    value = R[t2]:R[t];
    AArch32.SysRegWrite64(cp, ThisInstr(), value);
```

F5.1.105 MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

A1

| | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|----|---|---|

| Ra | | | | | | | | | | | | | | | | | | | | | | | |

T1 variant

MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
if Ra == '1111' then SEE MUL;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra); setflags = FALSE;
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- <Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
addend = SInt(R[a]); // addend = UInt(R[a]) produces the same final results
result = operand1 * operand2 + addend;
R[d] = result<31:0>;
if setflags then
  PSTATE.N = result<31>;
  PSTATE.Z = IsZeroBit(result<31:0>);
  // PSTATE.C, PSTATE.V unchanged
```

F5.1.106 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

A1

A1 variant

MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1

T1 variant

MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- <Ra> Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
addend   = SInt(R[a]); // addend   = UInt(R[a]) produces the same final results
result = addend - operand1 * operand2;
R[d] = result<31:0>;
```

F5.1.107 MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

MOV variant

Applies when `S == 0`.

`MOV{<c>}{<q>} <Rd>, #<const>`

MOVS variant

Applies when `S == 1`.

`MOVS{<c>}{<q>} <Rd>, #<const>`

Decode for all variants of this encoding

`d = UInt(Rd); setflags = (S == '1');` `(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);`

A2

A2 variant

`MOV{<c>}{<q>} <Rd>, #<imm16>` // <imm16> can not be represented in A1

`MOVW{<c>}{<q>} <Rd>, #<imm16>` // <imm16> can be represented in A1

Decode for this encoding

`d = UInt(Rd); setflags = FALSE;` `imm32 = ZeroExtend(imm4:imm12, 32);`
`if d == 15 then UNPREDICTABLE;`

T1

 MOVW{<c>}{<q>} <Rd>, #<imm16> // <imm16> can be represented in T1 or T2

Decode for this encoding

d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(imm4:i:imm3:imm8, 32);
 if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding A2, T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<imm8> Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<imm16> For encoding A2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T3: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T2: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then           // Can only occur for encoding A1
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F5.1.108 MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases [ASRS \(immediate\)](#), [ASR \(immediate\)](#), [LSLS \(immediate\)](#), [LSL \(immediate\)](#), [LSRS \(immediate\)](#), [LSR \(immediate\)](#), [RORS \(immediate\)](#), [ROR \(immediate\)](#), [RRXS](#), and [RRX](#). See [Alias conditions on page F5-2817](#) for details of when each alias is preferred.

A1

T2 variant

MOV<c>{<q>} <Rd>, <Rm> {, <shift> #<amount>} // Inside IT block
 MOV<v>{<q>} <Rd>, <Rm> {, <shift> #<amount>} // Outside IT block

Decode for this encoding

```
d = UInt(Rd); m = UInt(Rm); setflags = !InITBlock();
(shift_t, shift_n) = DecodeImmShift(op, imm5);
if op == '00' && imm5 == '00000' && InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If op == '00' && imm5 == '00000' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passed its condition code check.
- The instruction executes as NOP, as if it failed its condition code check.
- The instruction executes as MOV Rd, Rm.

T3

MOV, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && type == 11.

MOV{<c>}{<q>} <Rd>, <Rm>, RRX

MOV, shift or rotate by value variant

Applies when $S == 0 \ \&\& \ !(\text{imm3} == 000 \ \&\& \ \text{imm2} == 00 \ \&\& \ \text{type} == 11)$.

MOV{<c>}.W <Rd>, <Rm> {, LSL #0} // <Rd>, <Rm> can be represented in T1
 MOV<c>.W <Rd>, <Rm> {, <shift> #<amount>} // Inside IT block, and <Rd>, <Rm>, <shift>, <amount> can be represented in T2
 MOV{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

MOVS, rotate right with extend variant

Applies when $S == 1 \ \&\& \ \text{imm3} == 000 \ \&\& \ \text{imm2} == 00 \ \&\& \ \text{type} == 11$.

MOVS{<c>}{<q>} <Rd>, <Rm>, RRX

MOVS, shift or rotate by value variant

Applies when $S == 1 \ \&\& \ !(\text{imm3} == 000 \ \&\& \ \text{imm2} == 00 \ \&\& \ \text{type} == 11)$.

MOVS.W <Rd>, <Rm> {, <shift> #<amount>} // Outside IT block, and <Rd>, <Rm>, <shift>, <amount> can be represented in T1 or T2
 MOVS{<c>}{<q>} <Rd>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|------------------|---|---|
| ASRS (immediate) | T3 (MOVS, shift or rotate by value), A1 (MOVS, shift or rotate by value) | $S == '1' \ \&\& \ \text{type} == '10'$ |
| ASRS (immediate) | T2 | $\text{op} == '10' \ \&\& \ !\text{InITBlock}()$ |
| ASR (immediate) | T3 (MOV, shift or rotate by value), A1 (MOV, shift or rotate by value) | $S == '0' \ \&\& \ \text{type} == '10'$ |
| ASR (immediate) | T2 | $\text{op} == '10' \ \&\& \ \text{InITBlock}()$ |
| LSLS (immediate) | T3 (MOVS, shift or rotate by value) | $S == '1' \ \&\& \ \text{imm3:Rd:imm2} != '000xxxx00' \ \&\& \ \text{type} == '00'$ |
| LSLS (immediate) | A1 (MOVS, shift or rotate by value) | $S == '1' \ \&\& \ \text{imm5} != '00000' \ \&\& \ \text{type} == '00'$ |
| LSLS (immediate) | T2 | $\text{op} == '00' \ \&\& \ \text{imm5} != '00000' \ \&\& \ !\text{InITBlock}()$ |

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#). ARM deprecates use of the instruction if <Rn> is the PC.
- For the MOVS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. ARM deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or RRX argument is specified.

For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The instruction must either be outside an IT block or the last instruction of an IT block.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. ARM deprecates use of the instruction if <Rd> is the PC.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

<shift> For encoding A1 and T3: is the type of shift to be applied to the source register, encoded in the "type" field. It can have the following values:

LSL when type = 00
 LSR when type = 01
 ASR when type = 10

ROR when type = 11

For encoding T2: is the type of shift to be applied to the source register, encoded in the "op" field. It can have the following values:

LSL when op = 00

LSR when op = 01

ASR when op = 10

<amount> For encoding A1 and T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = shifted;
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

F5.1.109 MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases [ASRS \(register\)](#), [ASR \(register\)](#), [LSLS \(register\)](#), [LSL \(register\)](#), [LSRS \(register\)](#), [LSR \(register\)](#), [RORS \(register\)](#), and [ROR \(register\)](#). See [Alias conditions](#) on page F5-2822 for details of when each alias is preferred.

A1

Flag setting variant

Applies when S == 1.

MOV{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

MOV{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

T1

Arithmetic shift right variant

Applies when op == 0100.

MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs> // Inside IT block
 MOV{<q>} <Rdm>, <Rdm>, ASR <Rs> // Outside IT block

Logical shift left variant

Applies when op == 0010.

MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs> // Inside IT block
 MOV{<q>} <Rdm>, <Rdm>, LSL <Rs> // Outside IT block

Logical shift right variant

Applies when op == 0011.

MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs> // Inside IT block
 MOV{<q>} <Rdm>, <Rdm>, LSR <Rs> // Outside IT block

Rotate right variant

Applies when `op == 0111`.

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs> // Inside IT block
MOV<{<q>} <Rdm>, <Rdm>, ROR <Rs> // Outside IT block
```

Decode for all variants of this encoding

```
if !(op IN {'0010', '0011', '0100', '0111'}) then SEE "Related encodings";
d = UInt(Rdm); m = UInt(Rdm); s = UInt(Rs);
setflags = !InITBlock(); shift_t = DecodeRegShift(op<2>:op<0>);
```

T2

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|------|---|----|---|---|----|----|----|----|----|---|---|----|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | type | S | Rm | 1 | 1 | 1 | 1 | Rd | 0 | 0 | 0 | 0 | Rs | | | | |

Flag setting variant

Applies when `S == 1`.

```
MOV<S.W <Rd>, <Rm>, <type> <Rs> // Outside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1
MOV<{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>
```

Not flag setting variant

Applies when `S == 0`.

```
MOV<c>.W <Rd>, <Rm>, <type> <Rs> // Inside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1
MOV<{<c>}{<q>} <Rd>, <Rm>, <type> <Rs>
```

Decode for all variants of this encoding

```
d = UInt(Rd); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

Related encodings: In encoding T1, for an `op` field value that is not described above, see [Data-processing \(two low registers\)](#) on page F3-2438.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|-----------------|-----------------------------|------------------------------|

Assembler symbols

| | |
|-------|--|
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <Rdm> | Is the general-purpose source register and the destination register, encoded in the "Rdm" field. |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field. |

<type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:

| | |
|-----|----------------|
| LSL | when type = 00 |
| LSR | when type = 01 |
| ASR | when type = 10 |
| ROR | when type = 11 |

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (result, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.110 MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

A1

A1 variant

MOVT{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

d = UInt(Rd); imm16 = imm4:imm12;
 if d == 15 then UNPREDICTABLE;

T1

T1 variant

MOVT{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

d = UInt(Rd); imm16 = imm4:i:imm3:imm8;
 if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <imm16> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.
 For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

F5.1.111 MRC

Move to general-purpose register from System register. This instruction copies the value of a System register to a general-purpose register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface on page E1-2312](#) and [General behavior of System registers on page G4-4151](#).

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable controls on page G1-3894](#).

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

A1

A1 variant

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
t = UInt(Rt); cp = if coproc<0> == '0' then 14 else 15;
// ARMv8-A removes UNPREDICTABLE for R13
```

T1

T1 variant

MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
t = UInt(Rt); cp = if coproc<0> == '0' then 14 else 15;
// ARMv8-A removes UNPREDICTABLE for R13
```

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<coproc> Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values:

- p14 when coproc<0> = 0
- p15 when coproc<0> = 1

- <opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc1" field.
- <Rt> Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the **PSTATE** condition flags.
- <CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.
- <CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.
- <opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc2" field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    bits(32) value = AArch32.SysRegRead(cp, ThisInstr());
    if t != 15 then
        R[t] = value;
    elseif AArch32.SysRegReadCanWriteAPSR(cp, ThisInstr()) then
        PSTATE.<N,Z,C,V> = value<31:28>;
        // value<27:0> are not used.
    else
        PSTATE.<N,Z,C,V> = bits(4) UNKNOWN;
```

F5.1.112 MRRC

Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface on page E1-2312](#) and [General behavior of System registers on page G4-4151](#).

In an implementation that includes EL2, MRRC accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable controls on page G1-3894](#).

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

A1

A1 variant

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
t = UInt(Rt); t2 = UInt(Rt2); cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

T1 variant

MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
t = UInt(Rt); t2 = UInt(Rt2); cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If $t == t2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|----------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <coproc> | Is the System register encoding space, encoded in the "coproc<0>" field. It can have the following values: p14 when coproc<0> = 0 p15 when coproc<0> = 1 |
| <opc1> | Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field. |
| <Rt> | Is the first general-purpose register that is transferred into, encoded in the "Rt" field. |
| <Rt2> | Is the second general-purpose register that is transferred into, encoded in the "Rt2" field. |
| <CRm> | Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field. |

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    value = AArch32.SysRegRead64(cp, ThisInstr());
    R[t] = value<31:0>;
    R[t2] = value<63:32>;
```

F5.1.113 MRS

Move Special register to general-purpose register moves the value of the *The Application Program Status Register, APSR* on page E1-2296, CPSR, or SPSR_<current_mode> into a general-purpose register.

ARM recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR* on page E1-2296.

An MRS that accesses the SPSR is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the CPSR returns an UNKNOWN value for the CPSR.{E, A, I, F, M} fields.

A1

A1 variant

MRS{<c>}{<q>} <Rd>, <spec_reg>

Decode for this encoding

```
d = UInt(Rd); read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE;
```

T1

T1 variant

MRS{<c>}{<q>} <Rd>, <spec_reg>

Decode for this encoding

```
d = UInt(Rd); read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-2406.

<q> See *Standard assembler syntax fields* on page F2-2406.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<spec_reg> Is the special register to be accessed, encoded in the "R" field. It can have the following values:

| | |
|-----------|------------|
| CPSR APSR | when R = 0 |
| SPSR | when R = 1 |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
if read_spsr then
    if PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else
        R[d] = SPSR[];
else
    // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
    bits(32) mask = '11111000 00001111 00000011 11011111';
    psr_val = GetPSRFromPSTATE() AND mask;
    if PSTATE.EL == EL0 then
        // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
        // and for the M field, bits<4:0>
        psr_val<9:6> = bits(4) UNKNOWN;
        psr_val<4:0> = bits(5) UNKNOWN;
    R[d] = psr_val;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User, M32_System} && read_spsr, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.114 MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or SPSR of the specified mode, or the value of *ELR_hyp* on page G1-3804, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MRS (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F5-3229.

      end
    end
  end

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.

F5.1.115 MSR (Banked register)

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or *SPSR* of the specified mode, or to *ELR_hyp* on page G1-3804.

MSR (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MSR (Banked register) instruction that is executed in a Secure EL1 mode would access *SPSR_mon*, *SP_mon*, or *LR_mon*, it is trapped to EL3.

The effect of using an MSR (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions* on page F5-3229.

            end
        end
    end
end
  
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.116 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the *The Application Program Status Register, APSR* on page E1-2296, *CPSR*, or *SPSR*<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of MSR is normally only useful at the Application level for writing to *APSR_nzcvq* (*CPSR_f*).

If an MSR (immediate) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE.M* is legal. See *Illegal changes to PSTATE.M* on page G1-3809.

An MSR (immediate) executed in User mode:

- Is **CONSTRAINED UNPREDICTABLE** if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher,

An MSR (immediate) executed in System mode is **CONSTRAINED UNPREDICTABLE** if it attempts to update the *SPSR*.

The *CPSR.E* bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value.

if mask == '0000' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $\text{mask} == '0000' \ \&\& \ R == '1'$, then one of the following behaviors must occur:

- The instruction is **UNDEFINED**.
- The instruction executes as **NOP**.

Notes for all encodings

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Move Special Register & Hints \(immediate\)](#) on page F4-2516.

Assembler symbols

<c> See [Standard assembler syntax fields](#) on page F2-2406.

<q> See [Standard assembler syntax fields](#) on page F2-2406.

<spec_reg> Is one of:

- `APSR_<bits>`.

- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

- c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
- x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
- s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
- f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvcq, g, or nzcvcqg. These map to the following CPSR_<fields> values:

- APSR_nzcvcq is the same as CPSR_f (mask == '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvcqg is the same as CPSR_fs (mask == '1100').

ARM recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register, APSR](#) on page E1-2296.

<imm> Is an immediate value. See [Modified immediate constants in A32 instructions](#) on page F2-2422 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(imm32, mask);
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System} && write_spsr, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.117 MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the *The Application Program Status Register, APSR* on page E1-2296, *CPSR* or *SPSR*<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the MSR instruction is being used at Application level and its destination is not *APSR_nzcvq* (*CPSR_f*).

If an MSR (register) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE.M* is legal. See *Illegal changes to PSTATE.M* on page G1-3809.

An MSR (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher.

An MSR (register) executed in System mode is UNPREDICTABLE if it attempts to update the *SPSR*.

The *CPSR.E* bit is writable from any mode using an MSR instruction. ARM deprecates using this to change its value.

A1

A1 variant

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
n = UInt(Rn); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

T1

T1 variant

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
n = UInt(Rn); write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<spec_reg> Is one of:

- APSR_<bits>.
- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

c mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
x mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
s mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
f mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvcq, g, or nzcvcqg. These map to the following CPSR_<fields> values:

- APSR_nzcvcq is the same as CPSR_f (mask == '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvcqg is the same as CPSR_fs (mask == '1100').

ARM recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register, APSR on page E1-2296](#).

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(R[n], mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(R[n], mask);
```

CONSTRAINED UNPREDICTABLE behavior

If write_spsr && PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.

F5.1.118 MUL, MULS

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rdm> Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. If omitted, <Rd> is used.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
operand1 = SInt(R[n]); // operand1 = UInt(R[n]) produces the same final results
operand2 = SInt(R[m]); // operand2 = UInt(R[m]) produces the same final results
result = operand1 * operand2;
R[d] = result<31:0>;
if setflags then
  PSTATE.N = result<31>;
  PSTATE.Z = IsZeroBit(result<31:0>);
  // PSTATE.C, PSTATE.V unchanged
```

F5.1.119 MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

MVN variant

Applies when `S == 0`.

`MVN{<c>}{<q>} <Rd>, #<const>`

MVNS variant

Applies when `S == 1`.

`MVNS{<c>}{<q>} <Rd>, #<const>`

Decode for all variants of this encoding

```
d = UInt(Rd); setFlags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

MVN variant

Applies when `S == 0`.

`MVN{<c>}{<q>} <Rd>, #<const>`

MVNS variant

Applies when `S == 1`.

`MVNS{<c>}{<q>} <Rd>, #<const>`

Decode for all variants of this encoding

```
d = UInt(Rd); setflags = (S == '1');  
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);  
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the MVNS variant, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  result = NOT(imm32);  
  if d == 15 then // Can only occur for A32 encoding  
    if setflags then  
      ALUExceptionReturn(result);  
    else  
      ALUWritePC(result);  
  else  
    R[d] = result;  
    if setflags then  
      PSTATE.N = result<31>;  
      PSTATE.Z = IsZeroBit(result);  
      PSTATE.C = carry;  
      // PSTATE.V unchanged
```

F5.1.120 MVN, MVNS (register)

Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

    PSTATE.C = carry;  
    // PSTATE.V unchanged
```

F5.1.122 NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

———— **Note** —————

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
// Do nothing
```

F5.1.123 ORN, ORNS (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

T1

Flag setting variant

Applies when S == 1.

ORNS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Not flag setting variant

Applies when S == 0.

ORN{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```

if Rn == '1111' then SEE MVN (immediate);
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
  
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.
- <const> An immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation

```

if ConditionPassed() then
  EncodingSpecificOperations();
  result = R[n] OR NOT(imm32);
  R[d] = result;
  if setflags then
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
  
```

F5.1.124 ORN, ORNS (register)

Bitwise OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

T1

ORN, rotate right with extend variant

Applies when $S == 0$ && $imm3 == 000$ && $imm2 == 00$ && $type == 11$.

ORN{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ORN, shift or rotate by value variant

Applies when $S == 0$ && $!(imm3 == 000 \&\& imm2 == 00 \&\& type == 11)$.

ORN{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

ORNS, rotate right with extend variant

Applies when $S == 1$ && $imm3 == 000$ && $imm2 == 00$ && $type == 11$.

ORNS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, RRX

ORNS, shift or rotate by value variant

Applies when $S == 1$ && $!(imm3 == 000 \&\& imm2 == 00 \&\& type == 11)$.

ORNS{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rn == '1111' then SEE MVN (register);
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); setFlags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.125 ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

ORR variant

Applies when $S == 0$.

ORR{<c>}{<q>} {<Rd>}, {<Rn>, #<const>

ORRS variant

Applies when $S == 1$.

ORRS{<c>}{<q>} {<Rd>}, {<Rn>, #<const>

Decode for all variants of this encoding

$d = \text{UInt}(Rd)$; $n = \text{UInt}(Rn)$; $\text{setFlags} = (S == '1')$;
 $(\text{imm32}, \text{carry}) = \text{A32ExpandImm}_C(\text{imm12}, \text{PSTATE.C})$;

T1

ORR variant

Applies when $S == 0$.

ORR{<c>}{<q>} {<Rd>}, {<Rn>, #<const>

ORRS variant

Applies when $S == 1$.

```
ORRS{<c>}{<q>} {<Rd>}, <Rn>, #<const>
```

Decode for all variants of this encoding

```
if Rn == '1111' then SEE MOV (immediate);  
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');  
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);  
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    result = R[n] OR imm32;  
    if d == 15 then // Can only occur for A32 encoding  
        if setflags then  
            ALUExceptionReturn(result);  
        else  
            ALUWritePC(result);  
    else  
        R[d] = result;  
        if setflags then  
            PSTATE.N = result<31>;  
            PSTATE.Z = IsZeroBit(result);  
            PSTATE.C = carry;  
            // PSTATE.V unchanged
```

F5.1.126 ORR, ORRS (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Data-processing \(shifted register\)](#) on page F3-2470

Assembler symbols

| | | | | | | | | | |
|----------|---|-----|----------------|-----|----------------|-----|----------------|-----|----------------|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rdn> | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field. | | | | | | | | |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none"> For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. | | | | | | | | |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

In T32 assembly:

- Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
- Inside an IT block, if ORR<c> <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else

```

```
        ALUwritePC(result);  
else  
    R[d] = result;  
    if setflags then  
        PSTATE.N = result<31>;  
        PSTATE.Z = IsZeroBit(result);  
        PSTATE.C = carry;  
        // PSTATE.V unchanged
```

F5.1.127 ORR, ORRS (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <Rs> | Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. | | | | | | | | |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

F5.1.128 PKHBT, PKHTB

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|------|---|---|----|---|---|----|--|--|

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <imm> For encoding A1: the shift to apply to the value read from <Rm>, encoded in imm5. Is one of:
- omitted No shift, encoded as 0b00000.
 - 1-31 Left shift by specified number of bits, encoded as a binary number.

- For encoding A1: the shift to apply to the value read from <Rm>, encoded in imm5. Is one of:
- omitted Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.
 - 1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

———— Note —————

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

For encoding T1: the shift to apply to the value read from <Rm>, encoded in imm3:imm2. For PKHBT, it is one of:

- omitted No shift, encoded as 0b00000.
- 1-31 Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

- omitted Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.
- 1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

———— Note —————

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand2 = Shift(R[m], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
R[d]<15:0> = if tbform then operand2<15:0> else R[n]<15:0>;
R[d]<31:16> = if tbform then R[n]<31:16>     else operand2<31:16>;
```

F5.1.129 PLD, PLDW (immediate)

Preload Data (immediate) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2321](#).

A1

Preload read variant

Applies when R == 1.

PLD{<c>}{<q>} [<Rn> {, #<+/-><imm>}]

Preload write variant

Applies when R == 0.

PLDW{<c>}{<q>} [<Rn> {, #<+/-><imm>}]

Decode for all variants of this encoding

```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn); imm32 = ZeroExtend(imm12, 32); add = (U == '1'); is_pldw = (R == '0');
```

T1

Preload read variant

Applies when W == 0.

PLD{<c>}{<q>} [<Rn> {, #<+><imm>}]

Preload write variant

Applies when W == 1.

PLDW{<c>}{<q>} [<Rn> {, #<+><imm>}]

Decode for all variants of this encoding

```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn); imm32 = ZeroExtend(imm12, 32); add = TRUE; is_pldw = (W == '1');
```

T2

Preload read variant

Applies when W == 0.

PLD{<c>}{<q>} [<Rn> {, #-<imm>}]

Preload write variant

Applies when W == 1.

PLDW{<c>}{<q>} [<Rn> {, #-<imm>}]

Decode for all variants of this encoding

```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn); imm32 = ZeroExtend(imm8, 32); add = FALSE; is_pldw = (W == '1');
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). Must be AL or omitted.
For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see [PLD \(literal\)](#).
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the offset is added to the base register.
- <imm> For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

F5.1.130 PLD (literal)

Preload Data (literal) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2321](#).

T1 variant

PLD{<c>}{<q>} <label> // Preferred syntax
 PLD{<c>}{<q>} [PC, #<+/-><imm>] // Alternative syntax

Decode for this encoding

imm32 = ZeroExtend(imm12, 32); add = (U == '1');

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). Must be AL or omitted.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <label> The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
 - + when U = 1
- <imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.
- For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
Hint_PreloadData(address);
```

F5.1.131 PLD, PLDW (register)

Preload Data (register) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2321](#).

T2 variant

PLI{<c>}{<q>} [<Rn> {, #<-><imm>}]

Decode for this encoding

if Rn == '1111' then SEE encoding T3;
 n = UInt(Rn); imm32 = ZeroExtend(imm8, 32); add = FALSE;

T3

T3 variant

PLI{<c>}{<q>} <label> // Preferred syntax
 PLI{<c>}{<q>} [PC, #<+/-><imm>] // Alternative syntax

Decode for this encoding

n = 15; imm32 = ZeroExtend(imm12, 32); add = (U == '1');

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). Must be AL or omitted.
 For encoding T1, T2 and T3: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <label> The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
 - when U = 0
 - + when U = 1
- + Specifies the offset is added to the base register.
- <imm> For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
 For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
 For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.
 For encoding T3: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
```

F5.1.133 PLI (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches on page E2-2321](#).

Rn

T1 variant

PLI{<c>}{<q>} [<Rn>, {+}<Rm> {, LSL #<amount>}]

Decode for this encoding

```
if Rn == '1111' then SEE PLI (immediate, literal);
n = UInt(Rn); m = UInt(Rm); add = TRUE;
(shift_t, shift_n) = (SRTType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). <c> must be AL or omitted.

For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

| | |
|----------|---|
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| + | Specifies the index register is added to the base register. |
| <Rm> | Is the general-purpose index register, encoded in the "Rm" field. |
| <shift> | Is the type of shift to be applied to the index register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
```

F5.1.134 POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

T1

| | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---------------|--|--|--|--|--|--|--|--|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | | | | | | | | | | 0 |
| 1 | 0 | 1 | 1 | 1 | 1 | 0 | P | register_list | | | | | | | | | | | |

T1 variant

```
POP{<c>}{<q>} <registers> // Preferred syntax
LDM{<c>}{<q>} SP!, <registers> // Alternate syntax
```

Decode for this encoding

```
registers = P:'0000000':register_list; UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

F5.1.135 POP (multiple registers)

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data

This instruction is an alias of the [LDM](#), [LDMIA](#), [LDMFD](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [LDM](#), [LDMIA](#), [LDMFD](#).
- The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode for this instruction.

A1

A1 variant

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(register_list) > 1.

T2

T2 variant

POP{<c>}.W <registers> // All registers in R0-R7, PC

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(P:M:register_list) > 1.

POP{<c>}{<q>} <registers>

is equivalent to

LDM{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(P:M:register_list) > 1.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<registers> For encoding A1: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#). If the SP is in the list, the value of the SP after such an instruction is UNKNOWN. The PC can be in the list. If it is, the instruction

branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#) on page E1-2293. ARM deprecates the use of this instruction with both the LR and the PC in the list.

For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#) on page F2-2413. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#) on page E1-2293. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation for all encodings

The description of [LDM](#), [LDMIA](#), [LDMFD](#) gives the operational pseudocode for this instruction.

F5.1.136 POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data

This instruction is an alias of the [LDR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [LDR \(immediate\)](#).
- The description of [LDR \(immediate\)](#) gives the operational pseudocode for this instruction.

A1

Post-indexed variant

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

T4

Post-indexed variant

POP{<c>}{<q>} <single_register_list>

is equivalent to

LDR{<c>}{<q>} <Rt>, [SP], #4

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<single_register_list>

Is the general-purpose register <Rt> to be loaded surrounded by { and }.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#) on page E1-2293.

Operation for all encodings

The description of [LDR \(immediate\)](#) gives the operational pseudocode for this instruction.

F5.1.137 PUSH

Push Multiple Registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

T1

| | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---------------|--|--|--|--|--|--|--|--|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | | | | | | | | | | 0 |
| 1 | 0 | 1 | 1 | 0 | 1 | 0 | M | register_list | | | | | | | | | | | |

T1 variant

```
PUSH{<c>}{<q>} <registers> // Preferred syntax
STMDB{<c>}{<q>} SP!, <registers> // Alternate syntax
```

Decode for this encoding

```
registers = '0':M:'000000':register_list; UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
```

```
else
    if UnalignedAllowed then
        MemU[address,4] = R[i];
    else
        MemA[address,4] = R[i];
    address = address + 4;
if registers<15> == '1' then // Only possible for encoding A1 or A2
    if UnalignedAllowed then
        MemU[address,4] = PCStoreValue();
    else
        MemA[address,4] = PCStoreValue();
SP = SP - 4*BitCount(registers);
```

F5.1.138 PUSH (multiple registers)

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data

This instruction is an alias of the [STMDB](#), [STMFD](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [STMDB](#), [STMFD](#).
- The description of [STMDB](#), [STMFD](#) gives the operational pseudocode for this instruction.

A1

A1 variant

PUSH{<c>}{<q>} <registers>

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(register_list) > 1.

T1

T1 variant

PUSH{<c>}.W <registers> // All registers in R0-R7, LR

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(M:register_list) > 1.

PUSH{<c>}{<q>} <registers>

is equivalent to

STMDB{<c>}{<q>} SP!, <registers>

and is the preferred disassembly when BitCount(M:register_list) > 1.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<registers> For encoding A1: is a list of two or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#). The SP and PC can be in the list. However:

- ARM deprecates the use of instructions that include the PC in the list.

- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#). The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

The description of [STMDB](#), [STMTD](#) gives the operational pseudocode for this instruction.

F5.1.139 PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data

This instruction is an alias of the [STR \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [STR \(immediate\)](#).
- The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

A1

Pre-indexed variant

PUSH{<c>}{<q>} <single_register_list>

is equivalent to

STR{<c>}{<q>} <Rt>, [SP, #-4]!

and is always the preferred disassembly.

T4

Pre-indexed variant

PUSH{<c>}{<q>} <single_register_list> // Standard syntax

is equivalent to

STR{<c>}{<q>} <Rt>, [SP, #-4]!

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<single_register_list>

Is the general-purpose register <Rt> to be stored surrounded by { and }.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding T4: is the general-purpose register to be transferred, encoded in the "Rt" field.

Operation for all encodings

The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

F5.1.140 QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range -2^{31} to $(2^{31} - 1)$, and writes the result to the destination register. If saturation occurs, it sets `PSTATE.Q` to 1.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|---|---|---|---|----|---|---|--|--|--|

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<7:0>) - SInt(R[m]<7:0>);
    diff2 = SInt(R[n]<15:8>) - SInt(R[m]<15:8>);
    diff3 = SInt(R[n]<23:16>) - SInt(R[m]<23:16>);
```

```
diff4 = SInt(R[n]<31:24>) - SInt(R[m]<31:24>);  
R[d]<7:0> = SignedSat(diff1, 8);  
R[d]<15:8> = SignedSat(diff2, 8);  
R[d]<23:16> = SignedSat(diff3, 8);  
R[d]<31:24> = SignedSat(diff4, 8);
```

F5.1.150 RBIT

Reverse Bits reverses the bit order in a 32-bit register.

A1

A1 variant

RBIT{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);
 if d == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

RBIT{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); n = UInt(Rn);
 if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The instruction executes with the additional decode: m = UInt(Rm);.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    for i = 0 to 31
        result<31-i> = R[m]<i>;
    R[d] = result;
```

F5.1.151 REV

Byte-Reverse Word reverses the byte order in a 32-bit register.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|----|-----|-----|-----|-----|---|---|---|---|----|

| cond | | | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

REV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);
 if d == 15 || m == 15 then UNPREDICTABLE;

T1

| | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|----|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 3 | 2 | 0 |
| 1 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | Rm | Rd | | |

T1 variant

REV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);

T2

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|----|----|----|----|----|---|---|---|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | Rn | 1 | 1 | 1 | 1 | Rd | 1 | 0 | 0 | 0 | Rm | | | |

T2 variant

REV{<c>}.W <Rd>, <Rm> // <Rd>, <Rm> can be represented in T1
 REV{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); n = UInt(Rn);
 if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: m = UInt(Rn);

- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$;
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
bits(32) result;
result<31:24> = R[m]<7:0>;
result<23:16> = R[m]<15:8>;
result<15:8> = R[m]<23:16>;
result<7:0> = R[m]<31:24>;
R[d] = result;
```

F5.1.152 REV16

Byte-Reverse Packed Halfword reverses the byte order in each 16-bit halfword of a 32-bit register.

A1

A1 variant

REV16{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);
 if d == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

REV16{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);

T2

T2 variant

REV16{<c>}.W <Rd>, <Rm> // <Rd>, <Rm> can be represented in T1
 REV16{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); n = UInt(Rn);
 if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: m = UInt(Rn);

- The instruction executes with the additional decode: $m = \text{UInt}(\text{Rm})$;
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
bits(32) result;
result<31:24> = R[m]<23:16>;
result<23:16> = R[m]<31:24>;
result<15:8> = R[m]<7:0>;
result<7:0> = R[m]<15:8>;
R[d] = result;
```

F5.1.153 REVSH

Byte-Reverse Signed Halfword reverses the byte order in the lower 16-bit halfword of a 32-bit register, and sign-extends the result to 32 bits.

A1

A1 variant

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);
 if d == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm);

T2

T2 variant

REVSH{<c>}.W <Rd>, <Rm> // <Rd>, <Rm> can be represented in T1
 REVSH{<c>}{<q>} <Rd>, <Rm>

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); n = UInt(Rn);
 if m != n || d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If m != n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes with the additional decode: $m = \text{UInt}(Rn)$;
- The instruction executes with the additional decode: $m = \text{UInt}(Rm)$;
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.
For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:8> = SignExtend(R[m]<7:0>, 24);
    result<7:0> = R[m]<15:8>;
    R[d] = result;
```

F5.1.154 RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore **PSTATE**. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Decrement After variant

Applies when P == 0 && U == 0.

RFEDA{<c>}{<q>} <Rn>{!}

Decrement Before variant

Applies when P == 1 && U == 0.

RFEDB{<c>}{<q>} <Rn>{!}

Increment After variant

Applies when P == 0 && U == 1.

RFE{IA}{<c>}{<q>} <Rn>{!}

Increment Before variant

Applies when P == 1 && U == 1.

RFEIB{<c>}{<q>} <Rn>{!}

Decode for all variants of this encoding

```
n = UInt(Rn);
wback = (W == '1'); increment = (U == '1'); wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
```

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

T2 variant

RFE{IA}{<c>}{<q>} <Rn>{!} // Outside or last in IT block

Decode for this encoding

```
n = UInt(Rn); wback = (W == '1'); increment = TRUE; wordhigher = FALSE;
if n == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- IA For encoding A1: is an optional suffix to indicate the Increment After variant.
For encoding T2: is an optional suffix for the Increment After form.
- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). <c> must be AL or omitted.
For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

RFEFA, RFEFA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if PSTATE.EL == EL2 then
    UNDEFINED;
  elseif PSTATE.EL == EL0 then
    UNPREDICTABLE; // UNDEFINED or NOP
  else
    address = if increment then R[n] else R[n]-8;
    if wordhigher then address = address+4;
    new_pc_value = MemA[address,4];
    spsr = MemA[address+4,4];
    if wback then R[n] = if increment then R[n]+8 else R[n]-8;
    AArch32.ExceptionReturn(new_pc_value, spsr);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.155 ROR (immediate)

Rotate Right (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This instruction is an alias of the [MOV, MOVS \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | |

| | | | | | | | | S | | | | | | | | | | | type | | | | | | | |

MOV, shift or rotate by value variant

Applies when !(imm3 == 000 && imm2 == 00).

ROR{<c>}{<q>} {<Rd>}, <Rm>, #<imm>

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR #<imm>

and is always the preferred disassembly.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

<imm> For encoding A1: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.
For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

Operation for all encodings

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

F5.1.156 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | |

Not flag setting variant

ROR<c> .W {<Rd>}, <Rm>, <Rs> // Inside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1

is equivalent to

MOV{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

ROR{<C>}{<q>} {<Rd>}, <Rm>, <Rs>

is equivalent to

MOV{<C>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

Assembler symbols

<C> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rdm> Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the first general-purpose source register, encoded in the "Rm" field.

<Rs> Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

Operation for all encodings

The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

F5.1.157 RORS (immediate)

Rotate Right, setting flags (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores [PSTATE](#) from `SPSR_<current_mode>`.
- The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is an alias of the [MOV, MOVS \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. ARM deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores [PSTATE](#) from `SPSR_<current_mode>`.
For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T3: is the general-purpose source register, encoded in the "Rm" field.
- <imm> For encoding A1: is the shift amount, in the range 1 to 31, encoded in the "imm5" field.
For encoding T3: is the shift amount, in the range 1 to 31, encoded in the "imm3:imm2" field.

Operation for all encodings

The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode for this instruction.

F5.1.158 RORS (register)

Rotate Right, setting flags (register) provides the value of the contents of a register rotated by a variable number of bits, and updates the condition flags based on the result. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register

This instruction is an alias of the [MOV, MOVS \(register-shifted register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode for this instruction.

A1

Flag setting variant

RORS{<c>}{<q>} {<Rd>}, <Rm>, <Rs>

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

T1

Rotate right variant

RORS{<q>} {<Rdm>}, <Rdm>, <Rs> // Outside IT block

is equivalent to

MOVS{<q>} <Rdm>, <Rdm>, ROR <Rs>

and is the preferred disassembly when !InITBlock().

T2

Flag setting variant

RORS.W {<Rd>}, <Rm>, <Rs> // Outside IT block, and <Rd>, <Rm>, <type>, <Rs> can be represented in T1

is equivalent to

MOVS{<c>}{<q>} <Rd>, <Rm>, ROR <Rs>

and is always the preferred disassembly.

RORS{<C>}{<Q>} {<Rd> ,} <Rm> , <Rs>

is equivalent to

MOVS{<C>}{<Q>} <Rd> , <Rm> , ROR <Rs>

and is always the preferred disassembly.

For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- | | |
|-----|----------------|
| LSL | when type = 00 |
| LSR | when type = 01 |
| ASR | when type = 10 |
| ROR | when type = 11 |
- <amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcvc) = AddWithCarry(NOT(R[n]), shifted, '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUwritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.163 RSB, RSBS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

| | | | | | | | | | | | | | | | | | | | | | |

| cond | | | | | | | | | | | | | | | | | | | | | |

Flag setting variant

Applies when S == 1.

RSBS{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

RSB{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | | | | | |
|--------|---|-----|----------------|-----|----------------|-----|----------------|-----|----------------|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. | | | | | | | | |
| <Rn> | Is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | Is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <type> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. | | | | | | | | |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzc;
```

F5.1.164 RSC, RSCS (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

RSC variant

Applies when `S == 0`.

`RSC{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

RSCS variant

Applies when `S == 1`.

`RSCS{<c>}{<q>} {<Rd>}, <Rn>, #<const>`

Decode for all variants of this encoding

`d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = A32ExpandImm(imm12);`

Assembler symbols

<c> See *Standard assembler syntax fields* on page F2-2406.

<q> See *Standard assembler syntax fields* on page F2-2406.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- For the RSCS variant, the instruction performs an exception return, that restores `PSTATE` from `SPSR_<current_mode>`.

- <Rn> Is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
- <const> An immediate value. See *Modified immediate constants in A32 instructions* on page F2-2422 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(NOT(R[n]), imm32, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.165 RSC, RSCS (register)

Reverse Subtract with Carry (register) subtracts a register value and the value of NOT (Carry flag) from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The RSCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
sum = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
```

```
R[d]<15:0> = diff<15:0>;  
R[d]<31:16> = sum<15:0>;  
PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if sum >= 0 then '11' else '00';
```

F5.1.170 SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

SBC variant

Applies when `S == 0`.

`SBC{<c>}{<q>} {<Rd>}, {<Rn>, #<const>`

SBCS variant

Applies when `S == 1`.

`SBCS{<c>}{<q>} {<Rd>}, {<Rn>, #<const>`

Decode for all variants of this encoding

`d = UInt(Rd); n = UInt(Rn); setflags = (S == '1');` `imm32 = A32ExpandImm(imm12);`

T1

SBC variant

Applies when `S == 0`.

`SBC{<c>}{<q>} {<Rd>}, {<Rn>, #<const>`

SBCS variant

Applies when `S == 1`.

SBCS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);  
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the SBCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then  
    EncodingSpecificOperations();  
    (result, nzcvc) = AddWithCarry(R[n], NOT(imm32), PSTATE.C);  
    if d == 15 then // Can only occur for A32 encoding  
        if setflags then  
            ALUExceptionReturn(result);  
        else  
            ALUWritePC(result);  
    else  
        R[d] = result;  
        if setflags then  
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.171 SBC, SBCS (register)

Subtract with Carry (register) subtracts an optionally-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | | | | | |
| <Rdn> | Is the first general-purpose source register and the destination register, encoded in the "Rdn" field. | | | | | | | | |
| <Rd> | For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. ARM deprecates using the PC as the destination register, but if the PC is used: <ul style="list-style-type: none"> For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293. For the SBCS variant, the instruction performs an exception return, that restores <code>PSTATE</code> from <code>SPSR_<current_mode></code>. <p>For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.</p> | | | | | | | | |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. | | | | | | | | |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. | | | | | | | | |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: <table> <tr> <td>LSL</td> <td>when type = 00</td> </tr> <tr> <td>LSR</td> <td>when type = 01</td> </tr> <tr> <td>ASR</td> <td>when type = 10</td> </tr> <tr> <td>ROR</td> <td>when type = 11</td> </tr> </table> | LSL | when type = 00 | LSR | when type = 01 | ASR | when type = 10 | ROR | when type = 11 |
| LSL | when type = 00 | | | | | | | | |
| LSR | when type = 01 | | | | | | | | |
| ASR | when type = 10 | | | | | | | | |
| ROR | when type = 11 | | | | | | | | |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. | | | | | | | | |

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzc;
  
```

F5.1.172 SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

Flag setting variant

Applies when S == 1.

SBCS{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

SBC{<c>}{<q>} {<Rd>}, <Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcV) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcV;
```

F5.1.173 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

A1

A1 variant

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(lsb); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

T1

T1 variant

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.
- <lsb> For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
- <width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsb + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsb>, 32);
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $msbit > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

F5.1.174 SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

A1

A1 variant

SDIV{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
 if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

T1

T1 variant

SDIV{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
 if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Overflow

If the signed integer division $0x80000000 / 0xFFFFFFFF$ is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to <Rd> must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is $0x80000000$.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(SInt(R[n])) / Real(SInt(R[m]]));
    R[d] = result<31:0>;
```

F5.1.175 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the `PSTATE.GE` flags.

A1

T1 variant

`SETEND{<q>} <endian_specifier> // Not permitted in IT block`

Decode for this encoding

```
set_bigend = (E == '1');
if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

`<q>` See [Standard assembler syntax fields on page F2-2406](#).

`<endian_specifier>` Is the endianness to be selected, and the value to be set in `PSTATE.E`, encoded in the "E" field.

It can have the following values:

LE when E = 0

BE when E = 1

Operation for all encodings

```
EncodingSpecificOperations();
AArch32.CheckSETENabled();
PSTATE.E = if set_bigend then '1' else '0';
```

F5.1.177 SEV

Send Event is a hint instruction. It causes an event to be signaled to all PEs in the multiprocessor system. For more information, see [Wait For Event and Send Event](#) on page G1-3872.

R[d]<7:0> = diff1<8:1>;  
R[d]<15:8> = diff2<8:1>;  
R[d]<23:16> = diff3<8:1>;  
R[d]<31:24> = diff4<8:1>;
```

F5.1.185 SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see [Secure Monitor Call \(SMC\) exception on page G1-3854](#).

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in User mode.

If the values of **HCR.TSC** and **SCR.SCD** are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32 this exception is taken to Monitor mode. When EL3 is using AArch64, it is the **SCR_EL3.SMD** bit, rather than the **SCR.SCD** bit, that can change the effect of executing an SMC instruction.

If the value of **HCR.TSC** is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of **SCR.SCD**. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information see [Traps to Hyp mode of Non-secure EL1 execution of SMC instructions on page G1-3901](#).

If the value of **HCR.TSC** is 0 and the value of **SCR.SCD** is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

T1 variant

SMC{<c>}{<q>} {#}<imm4>

Decode for this encoding

// imm4 is for assembly/disassembly only and is ignored by hardware
 if InITBlock() && !LastInITBlock() then UNPREDICTABLE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <imm4> Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but ARM does not recommend this.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();

    if !HaveEL(EL3) || PSTATE.EL == EL0 then
        UNDEFINED;

    AArch32.CheckForSMCTrap();

    if !ELUsingAArch32(EL3) then
        if SCR_EL3.SMD == '1' then
            // SMC disabled.
            UNDEFINED;
        else
            if SCR.SCD == '1' then
                // SMC disabled
                if IsSecure() then
                    // Executes either as a NOP or UNALLOCATED.
                    c = ConstrainUnpredictable(Unpredictable_SMD);
                    assert c IN {Constraint_NOP, Constraint_UNDEF};
                    if c == Constraint_NOP then EndOfInstruction();
                    UNDEFINED;

            if !ELUsingAArch32(EL3) then
                AArch64.CallSecureMonitor(Zeros(16));
            else
                AArch32.TakeSMCException();
```

CONSTRAINED UNPREDICTABLE behavior

If SCR.SCD == '1' && IsSecure(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

F5.1.186 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets `PSTATE.Q` to 1. It is not possible for overflow to occur during the multiplication.

    PSTATE.Q = '1';
```

F5.1.187 SMLAD, SMLADX

Signed Multiply Accumulate Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets `PSTATE.Q` to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications.

| <RdHi> | Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field. |

- <Rn> For encoding A1: is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the "Rn" field.
For encoding T1: is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the "Rn" field.
- <Rm> For encoding A1: is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.
For encoding T1: is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <x>), encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

F5.1.190 SMLALD, SMLALDX

Signed Multiply Accumulate Long Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64} .

A1

| | | | | | | | | | | | | | | | | | | | | | | |

  product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);  
  result = product1 + product2 + SInt(R[dHi]:R[dLo]);  
  R[dHi] = result<63:32>;  
  R[dLo] = result<31:0>;
```

F5.1.191 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets `PSTATE.Q` to 1. No overflow can occur during the multiplication.

A1

SMLAWB variant

Applies when `M == 0`.

`SMLAWB{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>`

SMLAWT variant

Applies when `M == 1`.

`SMLAWT{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>`

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra); m_high = (M == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1

Applies when `M == 0`.

`SMLAWB{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>`

SMLAWT variant

Applies when `M == 1`.

`SMLAWT{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>`

Decode for all variants of this encoding

```
if Ra == '1111' then SEE SMULWB, SMULWT;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra); m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.
- <Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
result = SInt(R[n]) * SInt(operand2) + (SInt(R[a]) << 16);
R[d] = result<47:16>;
if (result >> 16) != SInt(R[d]) then // Signed overflow
    PSTATE.Q = '1';
```

F5.1.192 SMLSD, SMLSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It adds the difference of the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets `PSTATE.Q` to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications or subtraction.

A1

- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand2 = if m_swap then ROR(R[m],16) else R[m];
product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
result = product1 + product2;
R[d] = result<31:0>;
if result != SInt(result<31:0>) then // Signed overflow
    PSTATE.Q = '1';
```

F5.1.198 SMULBB, SMULBT, SMULTB, SMULTT

Signed Multiply (halfwords) multiplies two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is written to the destination register. No overflow is possible during this instruction.

A1

SMULBB variant

Applies when M == 0 && N == 0.

SMULBB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULBT variant

Applies when M == 1 && N == 0.

SMULBT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULTB variant

Applies when M == 0 && N == 1.

SMULTB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULTT variant

Applies when M == 1 && N == 1.

SMULTT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
n_high = (N == '1'); m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

SMULBB variant

Applies when N == 0 && M == 0.

SMULBB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULBT variant

Applies when N == 0 && M == 1.

SMULBT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULTB variant

Applies when N == 1 && M == 0.

```
SMULTB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>
```

SMULTT variant

Applies when N == 1 && M == 1.

```
SMULTT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>
```

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);  
n_high = (N == '1'); m_high = (M == '1');  
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;  
  operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;  
  result = SInt(operand1) * SInt(operand2);  
  R[d] = result<31:0>;  
  // Signed overflow cannot occur
```

F5.1.199 SMULL, SMULLS

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

A1

Flag setting variant

Applies when S == 1.

SMULLS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Not flag setting variant

Applies when S == 0.

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

T1 variant

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $dHi == dLo$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|--------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <RdLo> | Is the general-purpose destination register for the lower 32 bits of the result, encoded in the "RdLo" field. |
| <RdHi> | Is the general-purpose destination register for the upper 32 bits of the result, encoded in the "RdHi" field. |
| <Rn> | Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field. |
| <Rm> | Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

F5.1.200 SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

A1

SMULWB variant

Applies when M == 0.

SMULWB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULWT variant

Applies when M == 1.

SMULWT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

SMULWB variant

Applies when M == 0.

SMULWB{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMULWT variant

Applies when M == 1.

SMULWT{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
product = SInt(R[n]) * SInt(operand2);
R[d] = product<47:16>;
// Signed overflow cannot occur
```

F5.1.201 SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

A1

SMUSD variant

Applies when M == 0.

SMUSD{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMUSDX variant

Applies when M == 1.

SMUSDX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

SMUSD variant

Applies when M == 0.

SMUSD{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

SMUSDX variant

Applies when M == 1.

SMUSDX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); m_swap = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
operand2 = if m_swap then ROR(R[m],16) else R[m];
product1 = SInt(R[n]<15:0>) * SInt(operand2<15:0>);
product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
result = product1 - product2;
R[d] = result<31:0>;
// Signed overflow cannot occur
```

F5.1.202 SRS, SRSDA, SRSDB, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see [Memory accesses on page F2-2412](#).

SRS is UNDEFINED in Hyp mode.

SRS is CONSTRAINED UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that [Table G1-5 on page G1-3796](#) does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

See [Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32 on page D1-1590](#).

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

T2 variant

SRS{IA}{<c>}{<q>} SP{!}, #<mode>

Decode for this encoding

wback = (W == '1'); increment = TRUE; wordhigher = FALSE;

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *SRS (T32)* on page K1-5468 and *SRS (A32)* on page K1-5468.

Assembler symbols

- IA For encoding A1: is an optional suffix to indicate the Increment After variant.
For encoding T2: is an optional suffix for the Increment After form.
- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). <c> must be AL or omitted.
For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <mode> Is the number of the mode whose Banked SP is used as the base register, encoded in the "mode" field. For details of PE modes and their numbers see [AArch32 PE mode descriptions on page G1-3796](#).

SRSFA, SRSEA, SRSFD, and SRSED are pseudo-instructions for SRSIB, SRSIA, SRSDB, and SRSDA respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation for all encodings

```

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then // UNDEFINED at EL2
      UNDEFINED;

    // Check for UNPREDICTABLE cases. The definition of UNPREDICTABLE does not permit these
    // to be security holes
    if PSTATE.M IN {M32_User, M32_System} then
      UNPREDICTABLE;
    elsif mode == M32_Hyp then // Check for attempt to access Hyp mode SP
  
```

```
    UNPREDICTABLE;
  elseif mode == M32_Monitor then // Check for attempt to access Monitor mode SP
    if !HaveEL(EL3) || !IsSecure() then
      UNPREDICTABLE;
    elseif !ELUsingAArch32(EL3) then
      AArch64.MonitorModeTrap();
  elseif BadMode(mode) then
    UNPREDICTABLE;

  base = Rmode[13,mode];
  address = if increment then base else base-8;
  if wordhigher then address = address+4;
  MemA[address,4] = LR;
  MemA[address+4,4] = SPSR[];
  if wback then Rmode[13,mode] = if increment then base+8 else base-8;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then // UNDEFINED at EL2
      UNDEFINED;

    // Check for UNPREDICTABLE cases. The definition of UNPREDICTABLE does not permit these
    // to be security holes
    if PSTATE.M IN {M32_User,M32_System} then
      UNPREDICTABLE;

    MemA[address+4,4] = SPSR[];
    if wback then Rmode[13,mode] = if increment then base+8 else base-8;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == M32_Hyp, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == M32_Monitor && (!HaveEL(EL3) || !IsSecure()), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If BadMode(mode), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction stores to the stack of the mode in which it is executed.
- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.

F5.1.203 SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

This instruction sets `PSTATE.Q` to 1 if the operation saturates.

A1

| | | | | | | | | | | | | | | | | | | | | |

Arithmetic shift right variant

Applies when `sh == 1 && !(imm3 == 000 && imm2 == 00)`.

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn>, ASR #<amount>

Logical shift left variant

Applies when `sh == 0`.

SSAT{<c>}{<q>} <Rd>, #<imm>, <Rn> {, LSL #<amount>}

Decode for all variants of this encoding

```
if sh == '1' && (imm3:imm2) == '0000' then SEE SSAT16;
d = UInt(Rd); n = UInt(Rn); saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm3:imm2);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|----------|--|
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <imm> | Is the bit position for saturation, in the range 1 to 32, encoded in the "sat_imm" field as <imm>-1. |
| <Rn> | Is the general-purpose source register, encoded in the "Rn" field. |
| <amount> | For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field. For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32. For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field. For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
```

F5.1.204 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

This instruction sets `PSTATE.Q` to 1 if the operation saturates.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <imm> Is the bit position for saturation, in the range 1 to 16, encoded in the "sat_imm" field as <imm>-1.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result1, sat1) = SignedSatQ(SInt(R[n]<15:0>), saturate_to);
    (result2, sat2) = SignedSatQ(SInt(R[n]<31:16>), saturate_to);
```

```
R[d]<15:0> = SignExtend(result1, 16);  
R[d]<31:16> = SignExtend(result2, 16);  
if sat1 || sat2 then  
    PSTATE.Q = '1';
```

F5.1.205 SSAX

Signed Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer subtraction and one 16-bit addition, and writes the results to the destination register. It sets `PSTATE.GE` according to the results.

A1

A1 variant

SSAX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

T1 variant

SSAX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum = SInt(R[n]<15:0>) + SInt(R[m]<31:16>);
    diff = SInt(R[n]<31:16>) - SInt(R[m]<15:0>);
```

```
R[d]<15:0> = sum<15:0>;  
R[d]<31:16> = diff<15:0>;  
PSTATE.GE<1:0> = if sum >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if diff >= 0 then '11' else '00';
```

F5.1.206 SSUB16

Signed Subtract 16 performs two 16-bit signed integer subtractions, and writes the results to the destination register. It sets `PSTATE.GE` according to the results of the subtractions.

A1

A1 variant

SSUB16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

SSUB16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<15:0>) - SInt(R[m]<15:0>);
    diff2 = SInt(R[n]<31:16>) - SInt(R[m]<31:16>);
    R[d]<15:0> = diff1<15:0>;
```

```
R[d]<31:16> = diff2<15:0>;  
PSTATE.GE<1:0> = if diff1 >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if diff2 >= 0 then '11' else '00';
```

F5.1.207 SSUB8

Signed Subtract 8 performs four 8-bit signed integer subtractions, and writes the results to the destination register. It sets `PSTATE.GE` according to the results of the subtractions.

A1

A1 variant

SSUB8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;

T1

T1 variant

SSUB8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
 if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff1 = SInt(R[n]<7:0>) - SInt(R[m]<7:0>);
    diff2 = SInt(R[n]<15:8>) - SInt(R[m]<15:8>);
    diff3 = SInt(R[n]<23:16>) - SInt(R[m]<23:16>);
```

```
diff4 = SInt(R[n]<31:24>) - SInt(R[m]<31:24>);  
R[d]<7:0> = diff1<7:0>;  
R[d]<15:8> = diff2<7:0>;  
R[d]<23:16> = diff3<7:0>;  
R[d]<31:24> = diff4<7:0>;  
PSTATE.GE<0> = if diff1 >= 0 then '1' else '0';  
PSTATE.GE<1> = if diff2 >= 0 then '1' else '0';  
PSTATE.GE<2> = if diff3 >= 0 then '1' else '0';  
PSTATE.GE<3> = if diff4 >= 0 then '1' else '0';
```

F5.1.208 STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the **DBGDTRRXint** System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2412.

In an implementation that includes EL2, the permitted STC access to **DBGDTRRXint** can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [Trapping general Non-secure System register accesses to debug registers](#) on page G1-3911.

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|------|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | | 0 | | |
| !=1111 | | | | 1 | 1 | 0 | P | U | 0 | W | 0 | Rn | | | | 0 | 1 | 0 | 1 | 1 | 1 | 0 | imm8 | |
| cond | | | | | | | | | | | | | | | | | | | | | | | | |

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

STC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 1$.

STC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

STC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Unindexed variant

Applies when $P == 0 \ \&\& \ U == 1 \ \&\& \ W == 0$.

STC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn); cp = 14;
imm32 = ZeroExtend(imm8:'00', 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15 \ \&\& \ wback$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15](#) on page K1-5457.

T1

| | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|---|----|----|----|----|----|----|---|------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 0 |

Unindexed variant

Applies when $P == 0 \ \&\& \ U == 1 \ \&\& \ W == 0$.

STC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn); cp = 14;
imm32 = ZeroExtend(imm8:'00', 32); index = (P == '1'); add = (U == '1'); wback = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15 on page K1-5457](#).

Assembler symbols

| | |
|----------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | For the offset or unindexed variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the offset, post-indexed or pre-indexed variant: is the general-purpose base register, encoded in the "Rn" field. |
| <option> | Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction. |

- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
 - + when U = 1
- <imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckSystemAccess(cp, ThisInstr());
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register read from DBGDTRRXint.
    MemA[address,4] = DBGDTR_EL0[];

    if wback then R[n] = offset_addr;
```

F5.1.209 STL

Store-Release Word stores a word from a register to memory. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page B2-90.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2355. For information about memory accesses see [Memory accesses](#) on page F2-2412.

T1 variant

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
```

```
Mem0[address, 4] = R[t];  
R[d] = ZeroExtend('0');  
else  
R[d] = ZeroExtend('1');
```

F5.1.212 STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page B2-90.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2355. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

A1 variant

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

T1 variant

STLEXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | | | | |
|------|--|---|----------------------------------|---|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . | | | | |
| <q> | See Standard assembler syntax fields on page F2-2406 . | | | | |
| <Rd> | Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: <table><tr><td>0</td><td>If the operation updates memory.</td></tr><tr><td>1</td><td>If the operation fails to update memory.</td></tr></table> | 0 | If the operation updates memory. | 1 | If the operation fails to update memory. |
| 0 | If the operation updates memory. | | | | |
| 1 | If the operation fails to update memory. | | | | |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. | | | | |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. | | | | |

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        Mem0[address, 1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

F5.1.213 STLEXD

Store-Release Exclusive Doubleword stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page B2-90.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2355. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

A1 variant

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); t2 = t+1; n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If $Rt<0> == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $Rt<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If $Rt == '1110'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15](#) on page K1-5457.

T1

| | | | | | | | | | | | | | | | | | | | | | | | |

T1 variant

STLEXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); t2 = UInt(Rt2); n = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt> For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

<Rt2> For encoding A1: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian() then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address, 8) then
        Mem0[address, 8] = value;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

F5.1.214 STLEXH

Store-Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#) on page B2-90.

For more information about support for shared memory see [Synchronization and semaphores](#) on page E2-2355. For information about memory accesses see [Memory accesses](#) on page F2-2412.

```

F5.1.216 STM, STMIA, STMEA

Store Multiple (Increment After, Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

For details of related system instructions see [STM \(User registers\)](#).

A1

A1 variant

STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
STMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15 on page K1-5457](#).

T1

T1 variant

STM{IA}{<c>}{<q>} <Rn>!, <registers> // Preferred syntax
STMEA{<c>}{<q>} <Rn>!, <registers> // Alternate syntax, Empty Ascending stack

Decode for this encoding

```
n = UInt(Rn); registers = '00000000':register_list; wback = TRUE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15 on page K1-5457](#).

T2

T2 variant

```
STM{IA}{<c>}.W <Rn>{!}, <registers> // Preferred syntax, if <Rn>, '!' and <registers> can be represented in T1
STMEA{<c>}.W <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack, if <Rn>, '!' and <registers> can be represented in T1
STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
STMEA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Ascending stack
```

Decode for this encoding

```
n = UInt(Rn); registers = P:M:register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15 on page K1-5457](#).

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|------|--|
| IA | Is an optional suffix for the Increment After form. |
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| ! | The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0. |

<registers> For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN; // Only possible for encodings T1 and A1
            else
                MemA[address,4] = R[i];
                address = address + 4;
    if registers<15> == '1' then // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

F5.1.217 STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

A1

A1 variant

STM{<amode>}{<c>}{<q>} <Rn>, <registers>^

Decode for this encoding

```
n = UInt(Rn); registers = register_list; increment = (U == '1'); wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | | |
|----------------------|--|--|
| <amode> | is one of: | |
| DA | Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0. | |
| ED | Empty Descending. For this instruction, a synonym for DA. | |
| DB | Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0. | |
| FD | Full Descending. For this instruction, a synonym for DB. | |
| IA | Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1. | |
| EA | Empty Ascending. For this instruction, a synonym for IA. | |
| IB | Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1. | |
| FA | Full Ascending. For this instruction, a synonym for IB. | |

- <c> See [Standard assembler syntax fields](#) on page F2-2406.
- <q> See [Standard assembler syntax fields](#) on page F2-2406.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <registers> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#) on page F2-2413.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elseif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;

        if wordhigher then address = address+4;
        for i = 0 to 14
            if registers<i> == '1' then // Store User mode register
                MemA[address,4] = Rmode[i, M32_User];
                address = address + 4;
            if registers<15> == '1' then
                MemA[address,4] = PCStoreValue();
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.M IN {M32_User,M32_System}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

F5.1.218 STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#) on page F2-2413.

For details of related system instructions see [STM \(User registers\)](#).

A1

A1 variant

```
STMDA{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
STMED{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Empty Descending stack
```

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- | | |
|------|---|
| <c> | See Standard assembler syntax fields on page F2-2406. |
| <q> | See Standard assembler syntax fields on page F2-2406. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |

- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
                address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

F5.1.219 STMDB, STMF

Store Multiple Decrement Before (Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

For details of related system instructions see [STM \(User registers\)](#).

This instruction is used by the alias [PUSH \(multiple registers\)](#). See [Alias conditions on page F5-3059](#) for details of when each alias is preferred.

A1

A1 variant

STMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 STMF{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

T1

T1 variant

STMDB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 STMF{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Descending stack

Decode for this encoding

```
n = UInt(Rn); registers = P:M:register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $\text{BitCount}(\text{registers}) < 1$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If $\text{wback} \ \&\& \ \text{registers}\langle n \rangle == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If $\text{BitCount}(\text{registers}) == 1$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If $\text{registers}\langle 13 \rangle == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If $\text{registers}\langle 15 \rangle == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|---|------------|--|
| PUSH (multiple registers) | T1 | $W == '1' \ \&\& \ Rn == '1101' \ \&\& \ \text{BitCount}(M:\text{register_list}) > 1$ |
| PUSH (multiple registers) | A1 | $W == '1' \ \&\& \ Rn == '1101' \ \&\& \ \text{BitCount}(\text{register_list}) > 1$ |

Assembler symbols

| | |
|-------------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| ! | The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0. |
| <registers> | <p>For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.</p> |

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN; // Only possible for encoding A1
            else
                MemA[address,4] = R[i];
                address = address + 4;
    if registers<15> == '1' then // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
  
```

F5.1.220 STMIB, STMFA

Store Multiple Increment Before (Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC on page F2-2413](#).

For details of related system instructions see [STM \(User registers\)](#).

A1

A1 variant

STMIB{<c>}{<q>} <Rn>{!}, <registers> // Preferred syntax
 STMFA{<c>}{<q>} <Rn>{!}, <registers> // Alternate syntax, Full Ascending stack

Decode for this encoding

```
n = UInt(Rn); registers = register_list; wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If BitCount(registers) < 1, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, ARM deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
                address = address + 4;
        if registers<15> == '1' then
            MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

F5.1.221 STR (immediate)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

This instruction is used by the alias [PUSH \(single register\)](#). See [Alias conditions on page F5-3065](#) for details of when each alias is preferred.

A1

Offset variant

Applies when P == 1 && W == 0.

STR{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

STR{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

STR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>!]

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE STRT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

| | | | | | | | | | | | | | | | |

| 1 | 0 | 0 | 1 | 0 | Rt | imm8 | | | | | | | | | | |

T2 variant

STR{<c>}{<q>} <Rt>, [SP{, #<+><imm>}]

Decode for this encoding

t = UInt(Rt); n = 13; imm32 = ZeroExtend(imm8:'00', 32);
 index = TRUE; add = TRUE; wback = FALSE;

T3

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|--------|----|-------|----|----|--|--|--|--|--|--|--|--|--|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | | | | | | | | | | | | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | !=1111 | Rt | imm12 | | | | | | | | | | | | | | |

Rn

T3 variant

STR{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // <Rt>, <Rn>, <imm> can be represented in T1 or T2
 STR{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

if Rn == '1111' then UNDEFINED;
 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
 index = TRUE; add = TRUE; wback = FALSE;
 if t == 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

T4

Offset variant

Applies when P == 1 && U == 0 && W == 0.

STR{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when P == 0 && W == 1.

STR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]

Pre-indexed variant

Applies when P == 1 && W == 1.

STR{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if P == '1' && U == '1' && W == '0' then SEE STRT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Alias conditions

| Alias | of variant | is preferred when |
|--|------------------|---|
| PUSH (single register) | A1 (pre-indexed) | $P == '1' \ \&\& \ U == '0' \ \&\& \ W == '1' \ \&\& \ Rn == '1101' \ \&\& \ imm12 == '000000000100'$ |
| PUSH (single register) | T4 (pre-indexed) | $Rn == '1101' \ \&\& \ U == '0' \ \&\& \ imm8 == '00000100'$ |

Assembler symbols

| | |
|-------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For encoding T1, T2, T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding T1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when $U = 0$ + when $U = 1$ |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4. For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4. For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field. |

Operation for all encodings

```

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);

    if wback then R[n] = offset_addr;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = R[t];
    if wback then R[n] = offset_addr;
  
```

F5.1.222 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

Offset variant

Applies when P == 1 && W == 0.

STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Post-indexed variant

Applies when P == 0 && W == 0.

STR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}]

Pre-indexed variant

Applies when P == 1 && W == 1.

STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE STRT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

| | | | | | | | | | | | | |
|----|----|----|----|----|----|---|----|----|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 6 | 5 | 3 | 2 | 0 |
| 0 | 1 | 0 | 1 | 0 | 0 | 0 | Rm | Rn | Rt | | | |

T1 variant

STR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, 0);

T2

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|--------|----|----|----|----|----|---|---|---|------|----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.

- <Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.
For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
+ when U = 1
- + Specifies the index register is added to the base register.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register on page F2-2410](#).
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    if t == 15 then // Only possible for encoding A1
        data = PCStoreValue();
    else
        data = R[t];
    MemU[address,4] = data;
    if wback then R[n] = offset_addr;
```

F5.1.223 STRB (immediate)

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when $P == 1$ && $W == 0$.

STRB{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when $P == 0$ && $W == 0$.

STRB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

STRB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE STRBT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback$ && $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $wback$ && $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

T1 variant

STRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5, 32);
 index = TRUE; add = TRUE; wback = FALSE;

T2

T2 variant

STRB{<c>}.W <Rt>, [<Rn> {, #<+><imm>}] // <Rt>, <Rn>, <imm> can be represented in T1
 STRB{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

if Rn == '1111' then UNDEFINED;
 t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm12, 32);
 index = TRUE; add = TRUE; wback = FALSE;
 if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

T3

Offset variant

Applies when P == 1 && U == 0 && W == 0.

STRB{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when $P == 0$ && $W == 1$.

STRB{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

STRB{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

Decode for all variants of this encoding

```
if P == '1' && U == '1' && W == '0' then SEE STRBT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback$ && $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $wback$ && $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding T1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field.

- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values:
- when U = 0
 - + when U = 1
- + Specifies the offset is added to the base register.
- <imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
- For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.
- For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
- For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

F5.1.224 STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

| cond | | | | | | | | | | | | | | | | | | | | |

Offset variant

Applies when $P == 1$ && $W == 0$.

STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Post-indexed variant

Applies when $P == 0$ && $W == 0$.

STRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}]

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then SEE STRBT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback$ && $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $wback$ && $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

F5.1.225 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

A1 variant

STRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,1] = R[t]<7:0>;
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STRB (immediate).

F5.1.226 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

Offset variant

Applies when P == 1 && W == 0.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15 || t2 == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If $Rt < 0 == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t < 0 = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

If $P == '0'$ && $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

if n == 15 || t == 15 || t2 == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
  
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$ || $t2 == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/Store dual](#), [Load/Store Exclusive](#), [Load-Acquire/Store-Release](#), and [table branch](#) on page F3-2466.

| <c> | See Standard assembler syntax fields on page F2-2406. |
| <q> | See Standard assembler syntax fields on page F2-2406. |
| <Rt> | For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rt2> | For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field. |
| <Rn> | For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding T1: is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
address = if index then offset_addr else R[n];
if address == Align(address, 8) then
    bits(64) data;
```

```
if BigEndian() then
    data<63:32> = R[t];
    data<31:0> = R[t2];
else
    data<31:0> = R[t];
    data<63:32> = R[t2];
MemA[address,8] = data;
else
    MemA[address,4] = R[t];
    MemA[address+4,4] = R[t2];
if wback then R[n] = offset_addr;
```

F5.1.227 STRD (register)

Store Register Dual (register) calculates an address from a base register value and a register offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#) on page F2-2412.

A1

Offset variant

Applies when $P == 1$ && $W == 0$.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when $P == 0$ && $W == 0$.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt); t2 = t+1; n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$ || $t2 == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback$ && ($n == t$ || $n == t2$), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $wback$ && $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If $Rt<0> == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $t<0> = '0'$.
- The instruction executes with the additional decode: $t2 = t$.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when $Rt == '1111'$.

If $P == '0'$ && $W == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: $P = '1'$; $W = '0'$.
- The instruction executes with the additional decode: $P = '1'$; $W = '1'$.
- The instruction executes with the additional decode: $P = '0'$; $W = '0'$.

Notes for all encodings

    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

F5.1.228 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, stores a word from a register to the calculated address if the PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2355](#). For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

A1 variant

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn); imm32 = Zeros(32); // Zero offset
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

T1 variant

STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

- 0 If the operation updates memory.
- 1 If the operation fails to update memory.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<imm> For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

F5.1.229 STREXB

Store Register Exclusive Byte derives an address from a base register value, stores a byte from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores on page E2-2355](#). For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

A1 variant

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

T1 variant

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
d = UInt(Rd); t = UInt(Rt); n = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,2) then
```

```
MemA[address,2] = R[t]<15:0>;  
R[d] = ZeroExtend('0');  
else  
R[d] = ZeroExtend('1');
```

F5.1.232 STRH (immediate)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when P == 1 && W == 0.

STRH{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Post-indexed variant

Applies when P == 0 && W == 0.

STRH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Pre-indexed variant

Applies when P == 1 && W == 1.

STRH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If wback && n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

| | | | | | | | | | | | |
|----|----|----|----|----|------|----|----|---|---|---|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 6 | 5 | 3 | 2 | 0 | |
| 1 | 0 | 0 | 0 | 0 | imm5 | Rn | Rt | | | | |

T1 variant

STRH{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm5:'0', 32);
 index = TRUE; add = TRUE; wback = FALSE;

T2

| | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|--------|----|-------|----|----|--|--|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | | | 0 |

| Rn | | | | | | | | | | | | | | | | | | | | | | | |

Offset variant

Applies when P == 1 && U == 0 && W == 0.

STRH{<c>}{<q>} <Rt>, [<Rn> {, #-<imm>}]

Post-indexed variant

Applies when $P == 0$ && $W == 1$.

STRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>

Pre-indexed variant

Applies when $P == 1$ && $W == 1$.

STRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!

Decode for all variants of this encoding

```
if P == '1' && U == '1' && W == '0' then SEE STRHT;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); imm32 = ZeroExtend(imm8, 32);
index = (P == '1'); add = (U == '1'); wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback$ && $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding A1, T1, T2, T3: is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when $U = 0$ + when $U = 1$ |
| + | Specifies the offset is added to the base register. |

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation for all encodings

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

F5.1.233 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses on page F2-2412](#).

A1

Offset variant

Applies when $P == 1 \ \&\& \ W == 0$.

STRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Post-indexed variant

Applies when $P == 0 \ \&\& \ W == 0$.

STRH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Pre-indexed variant

Applies when $P == 1 \ \&\& \ W == 1$.

STRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```

if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
index = (P == '1'); add = (U == '1'); wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRTYPE_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If $wback \ \&\& \ n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $wback \ \&\& \ n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

Rn

T2 variant

STRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // <Rt>, <Rn>, <Rm> can be represented in T1
 STRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

Decode for this encoding

if Rn == '1111' then UNDEFINED;
 t = UInt(Rt); n = UInt(Rn); m = UInt(Rm);
 index = TRUE; add = TRUE; wback = FALSE;
 (shift_t, shift_n) = (SRTYPE_LSL, UInt(imm2));
 if t == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

| | |
|-------|---|
| <Rn> | For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| + | Specifies the index register is added to the base register. |
| <Rm> | Is the general-purpose index register, encoded in the "Rm" field. |
| <imm> | If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

F5.1.234 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see [Memory accesses](#) on page F2-2412.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|---|---|---|---|---|-------|---|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |

T1 variant

STRHT{<c>}{<q>} <Rt>, [<Rn> {, #+}<imm>]

Decode for this encoding

```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If $t == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|-------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | Is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| +/- | For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <Rm> | Is the general-purpose index register, encoded in the "Rm" field. |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

Operation for all encodings

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;           // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,2] = R[t]<15:0>;
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If $PSTATE.EL == EL2$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction executes as STRH (immediate).

F5.1.235 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see [Memory accesses on page F2-2412](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

A1

A1 variant

STRT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); postindex = TRUE; add = (U == '1');
register_form = FALSE; imm32 = ZeroExtend(imm12, 32);
if n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $n == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $n == 15$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

A2

A2 variant

STRT{<c>}{<q>} <Rt>, [<Rn>], {<+/-><Rm>{, <shift>}}

Decode for this encoding

```
t = UInt(Rt); n = UInt(Rn); m = UInt(Rm); postindex = TRUE; add = (U == '1');
register_form = TRUE; (shift_t, shift_n) = DecodeImmShift(type, imm5);
if n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

T1 variant

STRT{<c>}{<q>} <Rt>, [<Rn> {, #<+><imm>}]

Decode for this encoding

```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt); n = UInt(Rn); postindex = FALSE; add = TRUE;
register_form = FALSE; imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If t == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

| | |
|---------|--|
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rt> | For encoding A1 and A2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| +/- | For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <Rm> | Is the general-purpose index register, encoded in the "Rm" field. |
| <shift> | The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register on page F2-2410 . |
| + | Specifies the offset is added to the base register. |
| <imm> | For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field. |

Operation for all encodings

```

    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    MemU_unpriv[address,4] = data;
    if postindex then R[n] = offset_addr;
  
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STR (immediate).

F5.1.236 SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the `Align(PC, 4)` value to form a PC-relative address, and writes the result to the destination register. ARM recommends that, where possible, software avoids using this alias

This instruction is an alias of the [ADR](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [ADR](#).
- The description of [ADR](#) gives the operational pseudocode for this instruction.

A2

A2 variant

SUB{<c>}{<q>} <Rd>, PC, #<const>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when `imm12 == '000000000000'`.

T2

T2 variant

SUB{<c>}{<q>} <Rd>, PC, #<imm12>

is equivalent to

ADR{<c>}{<q>} <Rd>, <label>

and is the preferred disassembly when `i:imm3:imm8 == '000000000000'`.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with `imm32` equal to the offset. If the offset is negative, encoding A2 is used, with `imm32` equal to the size of the offset.

That is, the use of encoding A2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions on page F2-2422](#).

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with `imm32` equal to the offset. If the offset is negative, encoding T2 is used, with `imm32` equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of `imm32`. Permitted values of the size of the offset are 0-4095.

- | | |
|----------------------------|---|
| <code><imm12></code> | Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field. |
| <code><const></code> | An immediate value. See Modified immediate constants in A32 instructions on page F2-2422 for the range of values. |

Operation for all encodings

The description of [ADR](#) gives the operational pseudocode for this instruction.

F5.1.237 SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores PSTATE from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state on page G1-3835](#).
 - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see [ERET](#).
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

SUB variant

Applies when S == 0 && Rn != 11x1.

SUB{<c>}{<q>} {<Rd>}, <Rn>, #<const>

SUBS variant

Applies when S == 1 && Rn != 1101.

SUBS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

```
if Rn == '1111' && S == '0' then SEE ADR;
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = A32ExpandImm(imm12);
```

T1

T1 variant

```
SUB{<c>}{<q>} <Rd>, <Rn>, #<imm3> // Inside IT block
SUBS{<q>} <Rd>, <Rn>, #<imm3> // Outside IT block
```

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); setflags = !InITBlock(); imm32 = ZeroExtend(imm3, 32);

T2

T2 variant

SUB<c>{<q>} <Rdn>, #<imm8> // Inside IT block, and <Rdn>, <imm8> can be represented in T1
 SUB<c>{<q>} {<Rdn>}, <Rdn>, #<imm8> // Inside IT block, and <Rdn>, <imm8> cannot be represented in T1
 SUBS{<q>} <Rdn>, #<imm8> // Outside IT block, and <Rdn>, <imm8> can be represented in T1
 SUBS{<q>} {<Rdn>}, <Rdn>, #<imm8> // Outside IT block, and <Rdn>, <imm8> cannot be represented in T1

Decode for this encoding

d = UInt(Rdn); n = UInt(Rdn); setflags = !InITBlock(); imm32 = ZeroExtend(imm8, 32);

T3

SUB variant

Applies when S == 0.

SUB<c>.W {<Rd>}, <Rn>, #<const> // Inside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or T2
 SUB{<c>}{<q>} {<Rd>}, <Rn>, #<const>

SUBS variant

Applies when S == 1 && Rd != 1111.

SUBS.W {<Rd>}, <Rn>, #<const> // Outside IT block, and <Rd>, <Rn>, <const> can be represented in T1 or T2
 SUBS{<c>}{<q>} {<Rd>}, <Rn>, #<const>

Decode for all variants of this encoding

if Rd == '1111' && S == '1' then SEE CMP (immediate);
 if Rn == '1101' then SEE SUB (SP minus immediate);
 d = UInt(Rd); n = UInt(Rn); setflags = (S == '1'); imm32 = T32ExpandImm(i:imm3:imm8);
 if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

T4

T4 variant

SUB{<c>}{<q>} {<Rd>}, <Rn>, #<imm12> // <imm12> cannot be represented in T1, T2, or T3
 SUBW{<c>}{<q>} {<Rd>}, <Rn>, #<imm12> // <imm12> can be represented in T1, T2, or T3

Decode for this encoding

```
if Rn == '1111' then SEE ADR;
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd); n = UInt(Rn); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

T5

T5 variant

SUBS{<c>}{<q>} PC, LR, #<imm8>

Decode for this encoding

```
if Rn == '1110' && IsZero(imm8) then SEE ERET;
d = 15; n = UInt(Rn); setflags = TRUE; imm32 = ZeroExtend(imm8, 32);
if n != 14 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *SUBS PC, LR and related instructions (A32)* on page K1-5469 and *SUBS PC, LR and related instructions (T32)* on page K1-5468.

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rdn> Is the general-purpose source and destination register, encoded in the "Rdn" field.
- <imm8> For encoding T2: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
 For encoding T5: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
 If <Rn> is the LR, and zero is used, see [ERET](#).
- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:
 - For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
 - For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from [SPSR_<current_mode>](#). ARM deprecates use of this instruction unless <Rn> is the LR.
- For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
- <Rn> For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see [SUB, SUBS \(SP minus immediate\)](#). If the PC is used, see [ADR](#).
 For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
 For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see [SUB, SUBS \(SP minus immediate\)](#).

- <imm3> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
- <imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.
For encoding T3: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

In the T32 instruction set, MOVS{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcvc) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcvc;
```

F5.1.238 SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

SUBS{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Not flag setting variant

Applies when S == 0.

SUB{<c>}{<q>} {<Rd>}, {<Rn>, <Rm>, <type> <Rs>

Decode for all variants of this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
setflags = (S == '1'); shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|--------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rn> | Is the first general-purpose source register, encoded in the "Rn" field. |
| <Rm> | Is the second general-purpose source register, encoded in the "Rm" field. |
| <type> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. |

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzc) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzc;
```

F5.1.240 SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293*.
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from *SPSR_<current_mode>*.
 - The PE checks *SPSR_<current_mode>* for an illegal return event. See *Illegal return events from AArch32 state on page G1-3835*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

SUB variant

Applies when S == 0.

SUB{<c>}{<q>} {<Rd>}, SP, #<const>

SUBS variant

Applies when S == 1.

SUBS{<c>}{<q>} {<Rd>}, SP, #<const>

Decode for all variants of this encoding

d = UInt(Rd); setflags = (S == '1'); imm32 = A32ExpandImm(imm12);

T1

T1 variant

SUB{<c>}{<q>} {SP}, SP, #<imm7>

Decode for this encoding

d = 13; setflags = FALSE; imm32 = ZeroExtend(imm7:'00', 32);

T3 variant

SUB{<c>}{<q>} {<Rd>}, SP, #<imm12> // <imm12> cannot be represented in T1, T2, or T3
 SUBW{<c>}{<q>} {<Rd>}, SP, #<imm12> // <imm12> can be represented in T1, T2, or T3

Decode for this encoding

```
d = UInt(Rd); setflags = FALSE; imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <imm7> Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.
- <Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used:
 - For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).

- For the SUBS variant, the instruction performs an exception return, that restores **PSTATE** from **SPSR_<current_mode>**. ARM deprecates use of this instruction unless **<Rn>** is the LR.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.

For encoding T2: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcV) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcV;
```

F5.1.241 SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC* on page E1-2293.
- The SUBS variant of the instruction performs an exception return without the use of the stack. ARM deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores `PSTATE` from `SPSR_<current_mode>`.
 - The PE checks `SPSR_<current_mode>` for an illegal return event. See *Illegal return events from AArch32 state* on page G1-3835.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

A1

SUB, rotate right with extend variant

Applies when $S == 0$ && $imm5 == 00000$ && $type == 11$.

`SUB{<c>}{<q>}{<Rd>}, SP, <Rm>, RRX`

SUB, shift or rotate by value variant

Applies when $S == 0$ && $!(imm5 == 00000 \ \&\& \ type == 11)$.

`SUB{<c>}{<q>}{<Rd>}, SP, <Rm> {, <shift> #<amount>}`

SUBS, rotate right with extend variant

Applies when $S == 1$ && $imm5 == 00000$ && $type == 11$.

`SUBS{<c>}{<q>}{<Rd>}, SP, <Rm>, RRX`

SUBS, shift or rotate by value variant

Applies when $S == 1$ && $!(imm5 == 00000 \ \&\& \ type == 11)$.

`SUBS{<c>}{<q>}{<Rd>}, SP, <Rm> {, <shift> #<amount>}`

Decode for all variants of this encoding

```
d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|-----|------|----|------|------|----|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

SUB, rotate right with extend variant

Applies when S == 0 && imm3 == 000 && imm2 == 00 && type == 11.

SUB{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

SUB, shift or rotate by value variant

Applies when S == 0 && !(imm3 == 000 && imm2 == 00 && type == 11).

SUB{<c>}.W {<Rd>}, SP, <Rm> // <Rd>, <Rm> can be represented in T1 or T2
 SUB{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

SUBS, rotate right with extend variant

Applies when S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && type == 11.

SUBS{<c>}{<q>} {<Rd>}, SP, <Rm>, RRX

SUBS, shift or rotate by value variant

Applies when S == 1 && !(imm3 == 000 && imm2 == 00 && type == 11) && Rd != 1111.

SUBS{<c>}{<q>} {<Rd>}, SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then SEE CMP (register);
d = UInt(Rd); m = UInt(Rm); setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if (d == 15 && !setflags) || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. ARM deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC on page E1-2293](#).
- For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

- <Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
- | | |
|-----|----------------|
| LSL | when type = 00 |
| LSR | when type = 01 |
| ASR | when type = 10 |
| ROR | when type = 11 |
- <amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcV) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcV;
```

F5.1.242 SVC

Supervisor Call causes a Supervisor Call exception. For more information, see [Supervisor Call \(SVC\) exception on page G1-3853](#).

———— Note ————

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If *HCR.TGE* is set to 1, and the SVC is executed in Non-secure User mode. For more information, see [Supervisor Call exception, when the value of HCR.TGE is 1 on page G1-3829](#)

In these cases, the *HSR* identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see [Use of the HSR on page G4-4137](#). The immediate field in the *HSR*:

- If the SVC is unconditional:
 - For the T32 instruction, is the zero-extended value of the *imm8* field.
 - For the A32 instruction, is the least-significant 16 bits the *imm24* field.
- If the SVC is conditional, is UNKNOWN.

A1

A1 variant

SVC{<c>}{<q>} {#}<imm>

Decode for this encoding

imm32 = ZeroExtend(*imm24*, 32);

T1

T1 variant

SVC{<c>}{<q>} {#}<imm>

Decode for this encoding

imm32 = ZeroExtend(*imm8*, 32);

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <imm> For encoding A1: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.
- For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CallSupervisor(imm32<15:0>);
```

F5.1.243 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

A1

A1 variant

SXTAB{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1

T1 variant

SXTAB{<c>}{<q>} {<Rd>}, <Rn>, <Rm> {, ROR #<amount>}

Decode for this encoding

```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <amount> Is the rotate amount, encoded in the "rotate" field. It can have the following values:
 - (omitted) when rotate = 00
 - 8 when rotate = 01

16 when rotate = 10
24 when rotate = 11

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<7:0>, 32);
```

F5.1.244 SXTAB16

Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

A1

T1 variant

SXTB16{<c>}{<q>} {<Rd>}, {<Rm>} {, ROR #<amount>}

Decode for this encoding

d = UInt(Rd); m = UInt(Rm); rotation = UInt(rotate:'000');
 if d == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|----------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field. |
| <amount> | Is the rotate amount, encoded in the "rotate" field. It can have the following values: |
| | (omitted) when rotate = 00 |
| | 8 when rotate = 01 |
| | 16 when rotate = 10 |
| | 24 when rotate = 11 |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0> = SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = SignExtend(rotated<23:16>, 16);
```

F5.1.248 SXTH

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |

    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<15:0>, 32);
```

F5.1.249 TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|-----|-----|-----|-----|-----|-----|-----|---|---|---|---|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | Rn | (1) | (1) | (1) | (1) | (0) | (0) | (0) | (0) | 0 | 0 | 0 | H | Rm | | |

Byte variant

Applies when H == 0.

TBB{<c>}{<q>} [<Rn>, <Rm>] // Outside or last in IT block

Halfword variant

Applies when H == 1.

TBH{<c>}{<q>} [<Rn>, <Rm>, LSL #1] // Outside or last in IT block

Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm); is_tbh = (H == '1');
if m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.
- <Rm> For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.
For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if is_tbh then
    halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
  else
    halfwords = UInt(MemU[R[n]+R[m], 1]);
  BranchWritePC(PC + 2*halfwords);
```

F5.1.250 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn);
 (imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);

T1

T1 variant

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn);
 (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
 if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
 For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.
 For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F5.1.251 TEQ (register)

Test Equivalence (register) performs a bitwise exclusive OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|------|------|---|----|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 |
| !=1111 | | | | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | Rn | (0) | (0) | (0) | (0) | imm5 | type | 0 | Rm | | |
| cond | | | | | | | | | | | | | | | | | | | | | | |

Rotate right with extend variant

Applies when imm5 == 00000 && type == 11.

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm5 == 00000 && type == 11).

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = DecodeImmShift(type, imm5);

T1

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|------|----|----|----|----|------|------|----|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | Rn | (0) | imm3 | 1 | 1 | 1 | 1 | imm2 | type | Rm | | | | | |

Rotate right with extend variant

Applies when imm3 == 000 && imm2 == 00 && type == 11.

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm3 == 000 && imm2 == 00 && type == 11).

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
 if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
LSL when type = 00
LSR when type = 01
ASR when type = 10
ROR when type = 11
- <amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.
For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F5.1.252 TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|----|---|------|---|----|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| !=1111 | | | | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | Rn | (0) | (0) | (0) | (0) | Rs | 0 | type | 1 | Rm | | |
| cond | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

TEQ{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values:
 - LSL when type = 00
 - LSR when type = 01
 - ASR when type = 10
 - ROR when type = 11
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F5.1.253 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

A1

A1 variant

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn);
 (imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);

T1

T1 variant

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

n = UInt(Rn);
 (imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
 if n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
 For encoding T1: is the general-purpose source register, encoded in the "Rn" field.
- <const> For encoding A1: an immediate value. See [Modified immediate constants in A32 instructions on page F2-2422](#) for the range of values.
 For encoding T1: an immediate value. See [Modified immediate constants in T32 instructions on page F2-2420](#) for the range of values.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

F5.1.254 TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|------|------|---|----|---|---|--|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 7 | 6 | 5 | 4 | 3 | 0 | |
| !=1111 | | | | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | Rn | (0) | (0) | (0) | (0) | imm5 | type | 0 | Rm | | | |
| cond | | | | | | | | | | | | | | | | | | | | | | | |

Rotate right with extend variant

Applies when imm5 == 00000 && type == 11.

TST{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm5 == 00000 && type == 11).

TST{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = DecodeImmShift(type, imm5);

T1

| | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|----|----|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 3 | 2 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | Rm | Rn | | |

T1 variant

TST{<c>}{<q>} <Rn>, <Rm>

Decode for this encoding

n = UInt(Rn); m = UInt(Rm);
 (shift_t, shift_n) = (SRType_LSL, 0);

T2

| | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|------|----|----|----|----|------|------|----|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 14 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

Rotate right with extend variant

Applies when imm3 == 000 && imm2 == 00 && type == 11.

TST{<c>}{<q>} <Rn>, <Rm>, RRX

Shift or rotate by value variant

Applies when !(imm3 == 000 && imm2 == 00 && type == 11).

```
TST{<c>}.W <Rn>, <Rm> // <Rn>, <Rm> can be represented in T1  
TST{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
n = UInt(Rn); m = UInt(Rm);  
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);  
if n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|----------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rn> | For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field. |
| <Rm> | For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field. |
| <shift> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <amount> | For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm3:imm2" field as <amount> modulo 32. |

Operation for all encodings

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);  
  result = R[n] AND shifted;  
  PSTATE.N = result<31>;  
  PSTATE.Z = IsZeroBit(result);  
  PSTATE.C = carry;  
  // PSTATE.V unchanged
```

F5.1.255 TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|----|---|------|---|----|---|---|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 14 | 13 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| !=1111 | | | | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | Rn | (0) | (0) | (0) | (0) | Rs | 0 | type | 1 | Rm | | |
| cond | | | | | | | | | | | | | | | | | | | | | | | |

A1 variant

TST{<c>}{<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
n = UInt(Rn); m = UInt(Rm); s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|--------|--|
| <c> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <Rn> | Is the first general-purpose source register, encoded in the "Rn" field. |
| <Rm> | Is the second general-purpose source register, encoded in the "Rm" field. |
| <type> | Is the type of shift to be applied to the second source register, encoded in the "type" field. It can have the following values: LSL when type = 00 LSR when type = 01 ASR when type = 10 ROR when type = 11 |
| <Rs> | Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field. |

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  shift_n = UInt(R[s]<7:0>);
  (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
  result = R[n] AND shifted;
  PSTATE.N = result<31>;
  PSTATE.Z = IsZeroBit(result);
  PSTATE.C = carry;
  // PSTATE.V unchanged
```

F5.1.256 UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets `PSTATE.GE` according to the results of the additions.

A1

A1 variant

UADD16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

T1 variant

UADD16{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<15:0>) + UInt(R[m]<15:0>);
    sum2 = UInt(R[n]<31:16>) + UInt(R[m]<31:16>);
    R[d]<15:0> = sum1<15:0>;
```

```
R[d]<31:16> = sum2<15:0>;  
PSTATE.GE<1:0> = if sum1 >= 0x10000 then '11' else '00';  
PSTATE.GE<3:2> = if sum2 >= 0x10000 then '11' else '00';
```

F5.1.257 UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets `PSTATE.GE` according to the results of the additions.

A1

A1 variant

UADD8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

T1 variant

UADD8{<c>}{<q>} {<Rd>}, {<Rn>}, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = UInt(R[n]<7:0>) + UInt(R[m]<7:0>);
    sum2 = UInt(R[n]<15:8>) + UInt(R[m]<15:8>);
    sum3 = UInt(R[n]<23:16>) + UInt(R[m]<23:16>);
```

```
sum4 = UInt(R[n]<31:24>) + UInt(R[m]<31:24>);  
R[d]<7:0> = sum1<7:0>;  
R[d]<15:8> = sum2<7:0>;  
R[d]<23:16> = sum3<7:0>;  
R[d]<31:24> = sum4<7:0>;  
PSTATE.GE<0> = if sum1 >= 0x100 then '1' else '0';  
PSTATE.GE<1> = if sum2 >= 0x100 then '1' else '0';  
PSTATE.GE<2> = if sum3 >= 0x100 then '1' else '0';  
PSTATE.GE<3> = if sum4 >= 0x100 then '1' else '0';
```

F5.1.258 UASX

Unsigned Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer addition and one unsigned 16-bit subtraction, and writes the results to the destination register. It sets `PSTATE.GE` according to the results.

A1

A1 variant

UASX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

T1 variant

UASX{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
diff = UInt(R[n]<15:0>) - UInt(R[m]<31:16>);
sum = UInt(R[n]<31:16>) + UInt(R[m]<15:0>);
```

```
R[d]<15:0> = diff<15:0>;  
R[d]<31:16> = sum<15:0>;  
PSTATE.GE<1:0> = if diff >= 0 then '11' else '00';  
PSTATE.GE<3:2> = if sum >= 0x10000 then '11' else '00';
```

F5.1.259 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

A1

A1 variant

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(lsb); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

T1

T1 variant

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn);
lsbit = UInt(imm3:imm2); widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.
- <lsb> For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.
For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.
- <width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsb + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsb>, 32);
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $msbit > 31$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

F5.1.260 UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the ARMv8-A architecture. However:

- With the T32 instruction set, ARM deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

A1

A1 variant

UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

```
imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T1

T1 variant

UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T2

T2 variant

UDF{<c>}.W {#}<imm> // <imm> can be represented in T1
 UDF{<c>}{<q>} {#}<imm>

Decode for this encoding

```
imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). <c> must be AL or omitted.
For encoding T1 and T2: see [Standard assembler syntax fields on page F2-2406](#). ARM deprecates using any <c> value other than AL.
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.
For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.
For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

F5.1.261 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See [Divide instructions on page F1-2379](#) for more information about this instruction.

A1

| | | | | | | | | | | | | | | | | | | | | | | |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|----|---|---|---|---|----|
| 31 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | |
| !=1111 | | | | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | Rd | (1) | (1) | (1) | (1) | Rm | 0 | 0 | 0 | 1 | Rn |
| cond | | | | | | | | | | | Ra | | | | | | | | | | | |

A1 variant

UDIV{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
 if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE;

CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

T1

| | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|----|-----|-----|-----|-----|----|---|---|---|---|----|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 | 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

| | | | | | | | | | | | | | Ra | | | | | | | | | | |

T1 variant

UDIV{<c>}{<q>} {<Rd>}, <Rn>, <Rm>

Decode for this encoding

d = UInt(Rd); n = UInt(Rn); m = UInt(Rm); a = UInt(Ra);
 if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13

CONSTRAINED UNPREDICTABLE behavior

If Ra != '1111', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(UInt(R[n])) / Real(UInt(R[m])));
    R[d] = result<31:0>;
```

F5.1.262 UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

A1

| | | | | | | | | | | | | | | | | | | | | | | | |

T1 variant

UMAAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm);
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <RdLo> Is the general-purpose source register holding the first addend and the destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
- <RdHi> Is the general-purpose source register holding the second addend and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = UInt(R[n]) * UInt(R[m]) + UInt(R[dHi]) + UInt(R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
```

F5.1.269 UMLAL, UMLALS

Unsigned Multiply Accumulate Long multiplies two unsigned 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

A1

| | | | | | | | | | | | | | | | | |
|--------|-------|----|----|-------|----|----|-------|-------|-------|------|----|---|---|---|---|----|
| 31 | 28 27 | 26 | 25 | 24 23 | 22 | 21 | 20 19 | 16 15 | 12 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

| cond | | | | | | | | | | | | | | | | |

Flag setting variant

Applies when S == 1.

UMLALS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Not flag setting variant

Applies when S == 0.

UMLAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

| | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|-------|----|---|---|---|---|---|---|---|----|------|-------|---|---|---|---|----|---|---|
| 15 | 14 | 13 | 12 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 | 15 | 12 11 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |
| 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 0 | Rn | RdLo | RdHi | 0 | 0 | 0 | 0 | Rm | | |

T1 variant

UMLAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
dLo = UInt(RdLo); dHi = UInt(RdHi); n = UInt(Rn); m = UInt(Rm); setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// ARMv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If $dHi == dLo$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

T1 variant

USAT16{<c>}{<q>} <Rd>, #<imm>, <Rn>

Decode for this encoding

```
d = UInt(Rd); n = UInt(Rn); saturate_to = UInt(sat_imm);
if d == 15 || n == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <imm> Is the bit position for saturation, in the range 0 to 15, encoded in the "sat_imm" field.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result1, sat1) = UnsignedSatQ(SInt(R[n]<15:0>), saturate_to);
    (result2, sat2) = UnsignedSatQ(SInt(R[n]<31:16>), saturate_to);
```

```
R[d]<15:0> = ZeroExtend(result1, 16);  
R[d]<31:16> = ZeroExtend(result2, 16);  
if sat1 || sat2 then  
    PSTATE.Q = '1';
```

F5.1.281 USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets `PSTATE.GE` according to the results.

A1

| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Rd> | Is the general-purpose destination register, encoded in the "Rd" field. |
| <Rm> | Is the general-purpose source register, encoded in the "Rm" field. |
| <amount> | Is the rotate amount, encoded in the "rotate" field. It can have the following values: (omitted) when rotate = 00 8 when rotate = 01 16 when rotate = 10 24 when rotate = 11 |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<15:0>, 32);
```

F5.1.290 WFE

Wait For Event is a hint instruction that permits the PE to enter a low-power state until one of a number of events occurs, including events signaled by executing the SEV instruction on any PE in the multiprocessor system. For more information, see [Wait For Event and Send Event on page G1-3872](#).

As described in [Wait For Event and Send Event on page G1-3872](#), the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- [Traps to Undefined mode of EL0 execution of WFE and WFI instructions on page G1-3888](#).
- [Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions on page G1-3904](#).
- [Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode on page G1-3915](#).

        WaitForInterrupt();
```

F5.1.292 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see [The Yield instruction on page F1-2385](#).

F5.2 Encoding and use of Banked register transfer instructions

Software executing at EL1 or higher can use the MRS (Banked register) and MSR (Banked register) instructions to transfer values between the general-purpose registers and Special-purpose registers. One particular use of these instructions is for a hypervisor to save or restore the register values of a Guest OS. The following sections give more information about these instructions:

- [Register arguments in the Banked register transfer instructions.](#)
- [Usage restrictions on the Banked register transfer instructions on page F5-3229.](#)
- [Encoding the register argument in the Banked register transfer instructions on page F5-3230.](#)
- [Pseudocode support for the Banked register transfer instructions on page F5-3231.](#)

For descriptions of the instructions see [MRS \(Banked register\) on page F5-2832](#) and [MSR \(Banked register\) on page F5-2836](#).

F5.2.1 Register arguments in the Banked register transfer instructions

Figure F5-1 shows the Banked general-purpose registers and Special-purpose registers:

| | | Associated PE mode | | | | | | | |
|---------------------------|----------|--------------------|----------|------------|----------|-----------|----------|--------|---------|
| | | User or System | Hyp | Supervisor | Abort | Undefined | Monitor | IRQ | FIQ |
| General-purpose registers | R8_usr | | | | | | | | R8_fiq |
| | R9_usr | | | | | | | | R9_fiq |
| | R10_usr | | | | | | | | R10_fiq |
| | R11_usr | | | | | | | | R11_fiq |
| | R12_usr | | | | | | | | R12_fiq |
| | SP_usr | SP_hyp | SP_svc | SP_abt | SP_und | SP_mon | SP_irq | SP_fiq | |
| LR_usr | | LR_svc | LR_abt | LR_und | LR_mon | LR_irq | LR_fiq | | |
| Special-purpose registers | SPSR_hyp | SPSR_svc | SPSR_abt | SPSR_und | SPSR_mon | SPSR_irq | SPSR_fiq | | |
| | ELR_hyp | | | | | | | | |

For the general-purpose registers, if no other register is shown, the *current mode register* is the _usr register. So, for example, the full set of current mode registers, including the registers that are not banked:

- For Hyp mode, is {R0_usr - R12_usr, SP_hyp, LR_usr, SPSR_hyp, ELR_hyp}.
- For Abort mode, is {R0_usr - R12_usr, SP_abt, LR_abt, SPSR_abt}.

Figure F5-1 Banking of general-purpose and Special-purpose registers

Figure F5-1 is based on Figure G1-2 on page G1-3799, that shows the complete set of general-purpose registers and Special-purpose registers accessible in each mode.

Note

- System mode uses the same set of registers as User mode. Neither of these modes can access an SPSR, except that System mode can use the MRS (Banked register) and MSR (Banked register) instructions to access some SPSRs, as described in [Usage restrictions on the Banked register transfer instructions on page F5-3229](#).
- General-purpose registers R0-R7, that are not Banked, cannot be accessed using the MRS (Banked register) and MSR (Banked register) instructions.
- In addition to the registers shown in Figure F5-1, the DLR and DSPSR are AArch32 System registers that map onto the AArch64 Special-purpose registers DLR_ELO and DSPSR_ELO. However, DLR and DSPSR are not accessible using the MRS (Banked register) and MSR (Banked register) instructions.

Software using an MRS (Banked register) or MSR (Banked register) instruction specifies one of these registers using a name shown in Figure F5-1, or an alternative name for SP or LR. These registers can be grouped as follows:

R8-R12 Each of these registers has two Banked copies, _usr and _fiq, for example R8_usr and R8_fiq.

| | |
|----------------|--|
| SP | There is a Banked copy of SP for every mode except System mode. For example, SP_svc is the SP for Supervisor mode. |
| LR | There is a Banked copy of LR for every mode except System mode and Hyp mode. For example, LR_svc is the LR for Supervisor mode. |
| SPSR | There is a Banked copy of SPSR for every mode except System mode and User mode. |
| ELR_hyp | Except for the operations provided by MRS (Banked register) and MSR (Banked register), ELR_hyp is accessible only from Hyp mode. It is not Banked. |

F5.2.2 Usage restrictions on the Banked register transfer instructions

MRS (Banked register) and MSR (Banked register) instructions are CONSTRAINED UNPREDICTABLE if any of the following applies:

- The instruction is executed in User mode.
- The instruction accesses a Banked register that is not implemented, or that either:
 - Is not accessible from the current Privilege level and Security state.
 - Can be accessed from the current mode by using a different instruction.

[MSR/MRS Banked registers on page K1-5477](#) describes the permitted CONSTRAINED UNPREDICTABLE behavior.

An MRS (Banked register) or an MSR (Banked register) executed:

- At Non-secure EL1 cannot access any Hyp mode Banked registers.
- At Non-secure EL1 or EL2 cannot access any Monitor mode Banked registers.
- In a Secure mode other than Monitor mode cannot access any Hyp Banked registers.

This means that the Banked registers that MRS (Banked register) and MSR (Banked register) instructions cannot access are:

From Monitor mode

- The current mode registers R8_usr-R12_usr, SP_mon, LR_mon, and SPSR_mon.

From Hyp mode

- The Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The current mode registers R8_usr-R12_usr, SP_hyp, LR_usr, and SPSR_hyp.

———— Note —————

MRS (Banked register) and MSR (Banked register) instructions can access the current mode register [ELR_hyp](#).

From FIQ mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_fiq-R12_fiq, SP_fiq, LR_fiq, and SPSR_fiq.

From System mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_usr-R12_usr, SP_usr, and LR_usr.

From Supervisor mode, Abort mode, Undefined mode, and IRQ mode

- From Non-secure EL1, the Monitor mode registers SP_mon, LR_mon, and SPSR_mon.
- The Hyp mode registers SP_hyp, SPSR_hyp, and [ELR_hyp](#).
- The current mode registers R8_usr-R12_usr, SP_<current_mode>, LR_<current_mode>, and SPSR_<current_mode>.

If EL3 is using AArch64, all MRS (Banked register) and MSR (Banked register) accesses to the Monitor mode registers from Secure EL1 modes are trapped to EL3. See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32* on page D1-1590.

For more information, see:

- [Encoding the register argument in the Banked register transfer instructions.](#)
- [Pseudocode support for the Banked register transfer instructions](#) on page F5-3231.
- [MRS \(Banked register\)](#) on page F5-2832.
- [MSR \(Banked register\)](#) on page F5-2836.

———— **Note** —————

CONSTRAINED UNPREDICTABLE behavior must not give access to registers that are not accessible from the current Privilege level and Security state.

F5.2.3 Encoding the register argument in the Banked register transfer instructions

The MRS (Banked register) and MSR (Banked register) instructions include a 5-bit field, SYSm, and an R bit, that together encode the register argument for the instruction.

When the R bit is set to 0, the argument is a register other than a Banked copy of the SPSR, and [Table F5-1](#) shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

Table F5-1 Banked register encodings when R==0

| SYSm<4:3> | | | | |
|-----------|----------------------|----------------------|--------|-------------------------|
| SYSm<2:0> | 0b00 | 0b01 | 0b10 | 0b11 |
| 0b000 | R8_usr | R8_fiq | LR_irq | CONST. UNPREDICTABLE |
| 0b001 | R9_usr | R9_fiq | SP_irq | CONST. UNPREDICTABLE |
| 0b010 | R10_usr | R10_fiq | LR_svc | CONST. UNPREDICTABLE |
| 0b011 | R11_usr | R11_fiq | SP_svc | CONST. UNPREDICTABLE |
| 0b100 | R12_usr | R12_fiq | LR_abt | LR_mon |
| 0b101 | SP_usr | SP_fiq | SP_abt | SP_mon |
| 0b110 | LR_usr | LR_fiq | LR_und | ELR_hyp |
| 0b111 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | SP_und | SP_hyp |

When the R bit is set to 1, the argument is a Banked copy of the SPSR, and [Table F5-2](#) shows how the SYSm field defines the required register argument. In this table, CONST. UNPREDICTABLE indicates that behavior is CONSTRAINED UNPREDICTABLE.

Table F5-2 Banked register encodings when R==1

| SYSm<4:3> | | | | |
|-----------|----------------------|----------------------|----------------------|----------------------|
| SYSm<2:0> | 0b00 | 0b01 | 0b10 | 0b11 |
| 0b000 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | SPSR_irq | CONST. UNPREDICTABLE |
| 0b001 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE |
| 0b010 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | SPSR_svc | CONST. UNPREDICTABLE |

Table F5-2 Banked register encodings when R==1 (continued)

| SYSm<2:0> | SYSm<4:3> | | | |
|-----------|----------------------|----------------------|----------------------|----------------------|
| | 0b00 | 0b01 | 0b10 | 0b11 |
| 0b011 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE |
| 0b100 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | SPSR_abt | SPSR_mon |
| 0b101 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE |
| 0b110 | CONST. UNPREDICTABLE | SPSR_fiq | SPSR_und | SPSR_hyp |
| 0b111 | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE | CONST. UNPREDICTABLE |

F5.2.4 Pseudocode support for the Banked register transfer instructions

The pseudocode functions `BankedRegisterAccessValid()` and `SPSRAccessValid()` check the validity of MRS (Banked register) and MSR (Banked register) accesses. That is, they filter the accesses that are CONSTRAINED UNPREDICTABLE either because:

- They attempt to access a register that *Usage restrictions on the Banked register transfer instructions on page F5-3229* shows is not accessible.
- They use an SYSm<4:0> encoding that *Encoding the register argument in the Banked register transfer instructions on page F5-3230* shows as CONSTRAINED UNPREDICTABLE.

`BankedRegisterAccessValid()` applies to accesses to the banked general-purpose registers, or to `ELR_hyp`, and `SPSRAccessValid()` applies to accesses to the `SPSRs`.

Chapter F6

T32 and A32 Advanced SIMD and floating-point Instruction Descriptions

This chapter describes each instruction. It contains the following sections:

- [Alphabetical list of floating-point and Advanced SIMD instructions on page F6-3234.](#)

———— **Note** —————

Some headings in this chapter use the term *floating-point register*. This is an abbreviated description, and means a register in the Advanced SIMD and floating-point register file.

F6.1 Alphabetical list of floating-point and Advanced SIMD instructions

This section lists every floating-point and Advanced SIMD instruction in the T32 and A32 instruction sets. For details of the format used see [Format of instruction descriptions on page F2-2402](#).

This section is formatted so that each instruction description starts on a new page.

F6.1.1 AESD

AES single round decryption.

if InITBlock() then UNPREDICTABLE;
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

<dt> Is the data type, encoded in the "size" field. It can have the following values:

8 when size = 00

The following encodings are reserved:

- size = 01.
- size = 1x.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q[d>>1] = AESMixColumns(Q[m>>1]);
```

F6.1.5 FLDMDBX, FLDMIAX

FLDMX loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;

```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move on page F3-2448](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move on page F4-2532](#) for the A32 instruction set.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

- <Rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
- ! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
- <dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

F6.1.6 FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

ARM deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FSTMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

FSTMDBX{<c>}{<q>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

FSTMIAX{<c>}{<q>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If regs > 16 || (d+regs) > 16, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction if the register list had not gone out of range, become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move on page F3-2448](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move on page F4-2532](#) for the A32 instruction set.

Assembler symbols

<c> See [Standard assembler syntax fields on page F2-2406](#).

<q> See [Standard assembler syntax fields on page F2-2406](#).

- <Rn> Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, ARM deprecates use of the PC.
- ! Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
- <dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r]; address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

F6.1.7 SHA1C

SHA1 hash update (choose).

```

Notes for all encodings

Related encodings: See [Advanced SIMD data-processing on page F3-2454](#) for the T32 instruction set, or [Advanced SIMD data-processing on page F4-2541](#) for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).

- <dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
- S8 when U = 0, size = 00
 - S16 when U = 0, size = 01
 - S32 when U = 0, size = 10
 - U8 when U = 1, size = 00
 - U16 when U = 1, size = 01
 - U32 when U = 1, size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[Din[n+r],e,esize];
      op2 = Elem[Din[m+r],e,esize];
      absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
      if long_destination then
        Elem[Q[d>>1],e,2*esize] = absdiff<2*esize-1:0>;
      else
        Elem[D[d+r],e,esize] = absdiff<esize-1:0>;
  
```

F6.1.22 VABS

Vector Absolute takes the absolute value of each element in a vector, and places the results in a second vector. The floating-point version only clears the sign bit.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

F6.1.23 VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instruction VACLE. The pseudo-instruction is never the preferred disassembly.

op

64-bit SIMD vector variant

Applies when Q == 0.

VACL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

is equivalent to

VACGT{<c>}{<q>}.<dt> <Dd>, <Dm>, <Dn>

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when $Q == 1$.

$VACLT\{<c>\}\{<q>\}.<dt> \{<Qd>, \} <Qn>, <Qm>$

is equivalent to

$VACGT\{<c>\}\{<q>\}.<dt> <Qd>, <Qm>, <Qn>$

and is never the preferred disassembly.

Assembler symbols

- $<Dm>$ Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- $<Dn>$ Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- $<Qm>$ Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as $<Qm>*2$.
- $<Qn>$ Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as $<Qn>*2$.
- $<c>$ For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- $<q>$ See [Standard assembler syntax fields on page F2-2406](#).
- $<dt>$ Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
F32 when $sz = 0$
- $<Qd>$ Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as $<Qd>*2$.
- $<Dd>$ Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation for all encodings

The description of [VACGT](#) gives the operational pseudocode for this instruction.

F6.1.27 VADD (floating-point)

Vector Add (floating-point) adds corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] + Elem[D[m+r],e,esize];
```

F6.1.29 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see [VRADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

A1 variant

VADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```
if size == '11' then SEE "Related encodings";
if Vn<0> == '1' || Vm<0> == '1' then UNDEFINED;
esize = 8 << UInt(size); elements = 64 DIV esize;

        else
            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 + Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

F6.1.32 VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector

This instruction is a pseudo-instruction of the [VBIC \(immediate\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VBIC \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VBIC \(immediate\)](#) gives the operational pseudocode for this instruction.

64-bit SIMD vector variant

Applies when Q == 0.

VAND{<c>}{<q>}.<dt> {<Dd>}, <Dd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.<dt> <Dd>, #~<imm>

and is never the preferred disassembly.

128-bit SIMD vector variant

Applies when Q == 1.

VAND{<c>}{<q>}.<dt> {<Qd>}, <Qd>, #<imm>

is equivalent to

VBIC{<c>}{<q>}.<dt> <Qd>, #~<imm>

and is never the preferred disassembly.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> The data type used for <imm>. It can be either I16 or I32. I8, I64, and F32 are also permitted, but the resulting syntax is a pseudo-instruction.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <imm> Is a constant of the type specified by <dt> that is replicated to fill the destination register. For details of the range of constants available and the encoding of <dt> and <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions on page F2-2423](#).

Operation for all encodings

The description of [VBIC \(immediate\)](#) gives the operational pseudocode for this instruction.

F6.1.33 VAND (register)

Vector Bitwise AND (register) performs a bitwise AND operation between two registers, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

64-bit SIMD vector variant

Applies when Q == 0.

VAND{<c>}{<q>}{.<dt>} {<Dd>}, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VAND{<c>}{<q>}{.<dt>} {<Qd>}, <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
 d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

| | |
|------|---|
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | An optional data type. It is ignored by assemblers, and does not affect the encoding. |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

F6.1.34 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instruction VAND (immediate). The pseudo-instruction is never the preferred disassembly.

```

F6.1.38 VBSL

Vector Bitwise Select sets each bit in the destination to the corresponding bit from the first source operand when the original destination bit was 1, otherwise from the second source operand.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

            when VBitOps_VBSL D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]));
```

F6.1.39 VCEQ (immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

Assembler symbols

- <c> For encoding A1 and A2: see *Standard assembler syntax fields* on page F2-2406. This encoding must be unconditional.
 For encoding T1 and T2: see *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <dt> For encoding A1 and T1: is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
 - S8 when U = 0, size = 00
 - S16 when U = 0, size = 01
 - S32 when U = 0, size = 10
 - U8 when U = 1, size = 00
 - U16 when U = 1, size = 01
 - U32 when U = 1, size = 10
 For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
 - F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

enumeration VCGEtype {VCGEtype_signed, VCGEtype_unsigned, VCGEtype_fp};

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
      case type of
        when VCGEtype_signed test_passed = (SInt(op1) >= SInt(op2));
  
```

```
when VCGEtype_unsigned test_passed = (UInt(op1) >= UInt(op2));  
when VCGEtype_fp       test_passed = FPCompareGE(op1, op2, StandardFPSRValue());  
Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

F6.1.43 VCGT (immediate #0)

Vector Compare Greater Than Zero takes each element in a vector, and compares it with zero. If it is greater than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

      else
        test_passed = (SInt(ElEm[D[m+r],e,esize]) > 0);
      ElEm[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
  
```

F6.1.44 VCGT (register)

Vector Compare Greater Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instruction VCLT (register). The pseudo-instruction is never the preferred disassembly.

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "F:size" field. It can have the following values:
 - S8 when F = 0, size = 00
 - S16 when F = 0, size = 01
 - S32 when F = 0, size = 10
 - F32 when F = 1, size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      if floating_point then
        bits(esize) zero = FPZero('0');
        test_passed = FPCompareGE(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());
      else
        test_passed = (SInt(Elem[D[m+r],e,esize]) <= 0);
      Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
  
```

F6.1.46 VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros

This instruction is a pseudo-instruction of the [VCGE \(register\)](#) instruction. This means that:

- The encodings in this description are named to match the encodings of [VCGE \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGE \(register\)](#) gives the operational pseudocode for this instruction.

Operation for all encodings

The description of [VCGE \(register\)](#) gives the operational pseudocode for this instruction.

F6.1.47 VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

  EncodingSpecificOperations(); CheckAdvSIMDEnabled();  
  for r = 0 to regs-1  
    for e = 0 to elements-1  
      Elem[D[d+r],e,esize] = CountLeadingSignBits(Elem[D[m+r],e,esize])<esize-1:0>;
```

F6.1.48 VCLT (immediate #0)

Vector Compare Less Than Zero takes each element in a vector, and compares it with zero. If it is less than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

U8 when U = 1, size = 00
U16 when U = 1, size = 01
U32 when U = 1, size = 10
For encoding A2 and T2: is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values:
F32 when sz = 0
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation for all encodings

The description of [VCGT \(register\)](#) gives the operational pseudocode for this instruction.

F6.1.50 VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "size" field. It can have the following values:
 - I8 when size = 00
 - I16 when size = 01
 - I32 when size = 10
 The encoding size = 11 is reserved.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = CountLeadingZeroBits(Elem[M[m+r],e,esize])<esize-1:0>;
  
```

F6.1.51 VCMP

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the **PSTATE**.{N, Z, C, V} Condition flags by a subsequent **VMRS** instruction.

It raises an Invalid Operation exception only if either operand is a signaling NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
quiet_nan_exc = (E == '1'); with_zero = TRUE;
case size of
    when '10' esize = 32; d = UInt(Vd:D);
    when '11' esize = 64; d = UInt(D:Vd);
    
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the **FPSCR** flags being set as N=0, Z=0, C=1 and V=1.

VCMPe raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    case esize of
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
```

F6.1.52 VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the **PSTATE**.{N, Z, C, V} Condition flags by a subsequent **VMRS** instruction.

It raises an Invalid Operation exception if either operand is any type of NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTR** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

    when '11' esize = 64; d = UInt(D:Vd);
    
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the **FPSCR** flags being set as N=0, Z=0, C=1 and V=1.

VCMPe raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    case esize of
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            FPSCR.<N,Z,C,V> = FPCompare(S[d], op32, quiet_nan_exc, FPSCR);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            FPSCR.<N,Z,C,V> = FPCompare(D[d], op64, quiet_nan_exc, FPSCR);
```

F6.1.53 VCNT

Vector Count Set Bits counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VCNT{<c>}{<q>}.8 <Dd>, <Dm> // Encoded as Q = 0

128-bit SIMD vector variant

Applies when Q == 1.

For encoding T1: see *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = BitCount(Elem[D[m+r],e,esize])<size-1:0>;
```

F6.1.54 VCVT (between double-precision and single-precision)

Convert between double-precision and single-precision does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

      Elem[Q[d>>1],e,32] = FPConvert(Elem[Din[m],e,16], StandardFPSCRValue());
    else
      Elem[D[d],e,16] = FPConvert(Elem[Qin[m>>1],e,32], StandardFPSCRValue());
```

F6.1.56 VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt1> Is the data type for the elements of the destination vector, encoded in the "size:op" field. It can have the following values:
- | | |
|-----|-------------------------|
| F32 | when size = 10, op = 0x |
| S32 | when size = 10, op = 10 |
| U32 | when size = 10, op = 11 |
- <dt2> Is the data type for the elements of the source vector, encoded in the "size:op" field. It can have the following values:
- | | |
|-----|-------------------------|
| S32 | when size = 10, op = 00 |
| U32 | when size = 10, op = 01 |
| F32 | when size = 10, op = 1x |
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  bits(esize) result;
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[D[m+r],e,esize];
      if to_integer then
        result = FPToFixed(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
      else
        result = FixedToFP(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
      Elem[D[d+r],e,esize] = result;
  
```

F6.1.57 VCVT (floating-point to integer, floating-point)

Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in a second register.

[VCVT \(between floating-point and fixed-point, floating-point\)](#) describes conversions between floating-point and 16-bit integers.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

            Elem[D[d+r],e,esize] = result;
```

F6.1.60 VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when op == 0 && sf == 10.

VCVT{<c>}{<q>}.F32.<dt> <Sdm>, <Sdm>, #<fbits>

Single-precision scalar variant

Applies when op == 1 && sf == 10.

VCVT{<c>}{<q>}.<dt>.F32 <Sdm>, <Sdm>, #<fbits>

Double-precision scalar variant

Applies when op == 0 && sf == 11.

VCVT{<c>}{<q>}.F64.<dt> <Ddm>, <Ddm>, #<fbits>

Double-precision scalar variant

Applies when op == 1 && sf == 11.

VCVT{<c>}{<q>}.<dt>.F64 <Ddm>, <Ddm>, #<fbits>

Decode for all variants of this encoding

```

if sf != '1x' then UNDEFINED;
to_fixed = (op == '1'); unsigned = (U == '1');
size = if sx == '0' then 16 else 32;
frac_bits = size - UInt(imm4:i);
case sf of
    when '10' fp_size = 32; d = UInt(Vd:D);
    when '11' fp_size = 64; d = UInt(D:Vd);
if frac_bits < 0 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If `frac_bits < 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

Single-precision scalar variant

Applies when `op == 0` && `sf == 10`.

`VCVT{<c>}{<q>}.F32.<dt> <Sdm>, <Sdm>, #<fbits>`

Single-precision scalar variant

Applies when `op == 1` && `sf == 10`.

`VCVT{<c>}{<q>}.<dt>.F32 <Sdm>, <Sdm>, #<fbits>`

Double-precision scalar variant

Applies when `op == 0` && `sf == 11`.

`VCVT{<c>}{<q>}.F64.<dt> <Ddm>, <Ddm>, #<fbits>`

Double-precision scalar variant

Applies when `op == 1` && `sf == 11`.

`VCVT{<c>}{<q>}.<dt>.F64 <Ddm>, <Ddm>, #<fbits>`

Decode for all variants of this encoding

```

if sf != '1x' then UNDEFINED;
to_fixed = (op == '1'); unsigned = (U == '1');
size = if sx == '0' then 16 else 32;
frac_bits = size - UInt(imm4:i);
case sf of
  when '10' fp_size = 32; d = UInt(Vd:D);
  when '11' fp_size = 64; d = UInt(D:Vd);

if frac_bits < 0 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If `frac_bits < 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VCVT (between floating-point and fixed-point)* on page K1-5470.

Assembler symbols

- <c> See [Standard assembler syntax fields](#) on page F2-2406.
- <q> See [Standard assembler syntax fields](#) on page F2-2406.
- <dt> Is the data type for the fixed-point number, encoded in the "U:sx" field. It can have the following values:
- | | |
|-----|--------------------|
| S16 | when U = 0, sx = 0 |
| S32 | when U = 0, sx = 1 |
| U16 | when U = 1, sx = 0 |
| U32 | when U = 1, sx = 1 |
- <Sdm> Is the 32-bit name of the SIMD&FP destination and source register, encoded in the "Vd:D" field.
- <Ddm> Is the 64-bit name of the SIMD&FP destination and source register, encoded in the "D:Vd" field.
- <fbits> The number of fraction bits in the fixed-point number:
- If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]
 - If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i].

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    if to_fixed then
        bits(size) result;
        case fp_size of
            when 32
                result = FPToFixed(S[d], frac_bits, unsigned, FPSCR, FPRounding_ZERO);
                S[d] = Extend(result, 32, unsigned);
            when 64
                result = FPToFixed(D[d], frac_bits, unsigned, FPSCR, FPRounding_ZERO);
                D[d] = Extend(result, 64, unsigned);
        else
            case fp_size of
                when 32
                    S[d] = FixedToFP(S[d]<size-1:0>, frac_bits, unsigned, FPSCR, FPRounding_TIEEVEN);
                when 64
                    D[d] = FixedToFP(D[d]<size-1:0>, frac_bits, unsigned, FPSCR, FPRounding_TIEEVEN);
```

F6.1.61 VCVTA (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest with Ties to Away converts each element in a vector from floating-point to integer using the Round to Nearest with Ties to Away rounding mode, and places the results in a second vector.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit integers. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VCVTA{<q>}.<dt>.<dt2> <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VCVTA{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
rounding = FPDecodeRM(RM); unsigned = (op == '1');
esize = 32; elements = 2;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VCVTA{<q>}.<dt>.<dt2> <Dd>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VCVTA{<q>}.<dt>.<dt2> <Qd>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size != '10' then UNDEFINED;
rounding = FPDecodeRM(RM); unsigned = (op == '1');
esize = 32; elements = 2;
d = UInt(D:Vd); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

Assembler symbols

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the destination, encoded in the "op" field. It can have the following values:
- S32 when op = 0
 - U32 when op = 1
- <dt2> Is the data type for the elements of the source vector, encoded in the "size" field. It can have the following values:
- F32 when size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
bits(esize) result;
for r = 0 to regs-1
    for e = 0 to elements-1
        Elem[D[d+r],e,esize] = FPToFixed(Elem[D[m+r],e,esize], 0, unsigned,
            StandardFPSCRValue(), rounding);
```

F6.1.62 VCVTA (floating-point)

Convert floating-point to integer with Round to Nearest with Ties to Away converts a value in a register from floating-point to a 32-bit integer using the Round to Nearest with Ties to Away rounding mode, and places the result in a second register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

VCVTA{<q>}.<dt>.F32 <Sd>, <Sm>

Operation for all encodings

```
EncodingSpecificOperations(); CheckVFPEEnabled(TRUE);
case esize of
  when 32
    S[d] = FPToFixed(S[m], 0, unsigned, FPSCR, rounding);
  when 64
    S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
```

F6.1.63 VCVTB

Convert to or from a half-precision value in the bottom half of a single-precision register does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Half-precision to single-precision variant

Applies when `op == 0` && `sz == 0`.

 - F32 when size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

EncodingSpecificOperations(); CheckAdvSIMDEnabled();
bits(esize) result;
for r = 0 to regs-1
  for e = 0 to elements-1
    Elem[D[d+r],e,esize] = FPToFixed(Elem[D[m+r],e,esize], 0, unsigned,
                                     StandardFPSCRValue(), rounding);
  
```

F6.1.67 VCVTN (floating-point)

Convert floating-point to integer with Round to Nearest converts a value in a register from floating-point to a 32-bit integer using the Round to Nearest rounding mode, and places the result in a second register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

when 64  
    S[d] = FPToFixed(D[m], 0, unsigned, FPSCR, rounding);
```

F6.1.68 VCVTP (Advanced SIMD)

Vector Convert floating-point to integer with Round towards +Infinity converts each element in a vector from floating-point to integer using the Round towards +Infinity rounding mode, and places the results in a second vector.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit integers. Signed and unsigned integers are distinct.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

F6.1.70 VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the **FPSCR** and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the **CPACR**, **NSACR**, **HCPTR**, and **FPEXC** registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-3881*.

```

F6.1.71 VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

    when 64
        D[d] = FPDiv(D[n], D[m], FPSCR);
```

F6.1.73 VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

    when '01' esize = 16; elements = 4;
    when '10' esize = 8; elements = 8;
    when '11' UNDEFINED;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

T1

T1 variant

VDUP{<c>}{<q>}.<size> <Qd>, <Rt> // Encoded as Q = 1
 VDUP{<c>}{<q>}.<size> <Dd>, <Rt> // Encoded as Q = 0

Decode for this encoding

```

if Q == '1' && Vd<0> == '1' then UNDEFINED;
d = UInt(D:Vd); t = UInt(Rt); regs = if Q == '0' then 1 else 2;
case B:E of
    when '00' esize = 32; elements = 2;
    when '01' esize = 16; elements = 4;
    when '10' esize = 8; elements = 8;
    when '11' UNDEFINED;
if t == 15 then UNPREDICTABLE; // ARMv8-A removes UNPREDICTABLE for R13
    
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

- <c> See [Standard assembler syntax fields on page F2-2406](#). ARM strongly recommends that any VDUP instruction is unconditional, see [Conditional execution on page F2-2407](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> The data size for the elements of the destination vector. It must be one of:
- | | |
|----|---------------------------|
| 8 | Encoded as [b, e] = 0b10. |
| 16 | Encoded as [b, e] = 0b01. |
| 32 | Encoded as [b, e] = 0b00. |
- <Qd> The destination vector for a quadword operation.
- <Dd> The destination vector for a doubleword operation.
- <Rt> The ARM source register.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    scalar = R[t]<size-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

F6.1.74 VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see *Advanced SIMD scalars* on page F2-2432.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> The data size. It must be one of:
- | | |
|----|---|
| 8 | Encoded as imm4<0> = '1'. imm4<3:1> encodes the index [x] of the scalar. |
| 16 | Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar. |
| 32 | Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar. |
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  scalar = Elem[D[m],index,esize];
  for r = 0 to regs-1
    for e = 0 to elements-1
      Elem[D[d+r],e,esize] = scalar;
  
```

F6.1.75 VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

128-bit SIMD vector variant

Applies when Q == 1.

VEOR{<c>}{<q>}{.<dt>} {<Qd>}, <Qn>, <Qm>

Decode for all variants of this encoding

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
 d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;

Assembler symbols

<c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields* on page F2-2406.

- <q> See *Standard assembler syntax fields* on page F2-2406.
- <dt> An optional data type. It is ignored by assemblers, and does not affect the encoding.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
```

F6.1.76 VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows an example of the operation of VEXT doubleword operation for imm = 3.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the pseudo-instruction VEXT (multibyte elements). The pseudo-instruction is never the preferred disassembly.

```

Alias conditions

| Pseudo-instruction | is preferred when |
|---------------------------|-------------------|
| VEXT (multibyte elements) | Never |

Assembler symbols

| | |
|-------|--|
| <c> | For encoding A1: see Standard assembler syntax fields on page F2-2406 . This encoding must be unconditional. For encoding T1: see Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |
| <imm> | For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the "imm4" field. For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the "imm4" field. |

Operation for all encodings

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  if quadword_operation then
    Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
  else
    D[d] = (D[m]:D[n])<position+63:position>;
```

F6.1.77 VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector

This instruction is a pseudo-instruction of the **VEXT (byte elements)** instruction. This means that:

- The encodings in this description are named to match the encodings of **VEXT (byte elements)**.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of **VEXT (byte elements)** gives the operational pseudocode for this instruction.

For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to (64/<size>)-1. |

Operation for all encodings

The description of [VEXT \(byte elements\)](#) gives the operational pseudocode for this instruction.

F6.1.78 VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VFMA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VFMA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;

Decode for all variants of this encoding

```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size != '1x' then UNDEFINED;
advsimd = FALSE; op1_neg = (op == '1');
case size of
  when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

Assembler symbols

| | |
|------|--|
| <c> | For encoding A1: see <i>Standard assembler syntax fields</i> on page F2-2406. This encoding must be unconditional. For encoding A2, T1 and T2: see <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32 when sz = 0 |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |
| <Sd> | Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field. |
| <Sn> | Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field. |
| <Sm> | Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field. |

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
    if advsimd then // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                bits(eseize) op1 = Elem[D[n+r],e,eseize];
                if op1_neg then op1 = FPNeg(op1);
                Elem[D[d+r],e,eseize] = FPMu1Add(Elem[D[d+r],e,eseize],
                    op1, Elem[D[m+r],e,eseize], StandardFPSCRValue());
    else // VFP instruction
        case esize of
            when 32
                op32 = if op1_neg then FPNeg(S[n]) else S[n];
                S[d] = FPMu1Add(S[d], op32, S[m], FPSCR);
            when 64
                op64 = if op1_neg then FPNeg(D[n]) else D[n];
                D[d] = FPMu1Add(D[d], op64, D[m], FPSCR);
  
```

F6.1.79 VFMS

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VFMS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VFMS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
advsimd = TRUE; op1_neg = (op == '1');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
regs = if Q == '0' then 1 else 2;
```

A2

Single-precision scalar variant

Applies when size == 10.

VFMS{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>

Double-precision scalar variant

Applies when size == 11.

VFMS{<c>}{<q>}.F64 <Dd>, <Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
if size != '1x' then UNDEFINED;
advsimd = FALSE; op1_neg = (op == '1');
```

case size of
 when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
 when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);

T1

64-bit SIMD vector variant

Applies when Q == 0.

VFMS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VFMS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;

```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|--------|---|
| <c> | For encoding A1: see Standard assembler syntax fields on page F2-2406 . This encoding must be unconditional. |
| | For encoding T1: see Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <size> | Is the data size, encoded in the "size" field. It can have the following values: |
| | 8 when size = 00 |
| | 16 when size = 01 |
| | 32 when size = 10 |
| <list> | Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>: |
| | <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. |
| | <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. |
| | <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field. |

| | | | | | | | | | | | |
|--------------|--|-------------|---|--------------|--|--------------|---|--------------|---|--------------|--|
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. | | | | | | | | | | |
| <align> | When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access on page E2-2323 , and the encoding depends on <size>: <table><tr><td><size> == 8</td><td>Encoded in the "index_align<0>" field as 0.</td></tr><tr><td><size> == 16</td><td>Encoded in the "index_align<1:0>" field as 0b00.</td></tr><tr><td><size> == 32</td><td>Encoded in the "index_align<2:0>" field as 0b000.</td></tr></table> Whenever <align> is present, the permitted values and encoding depend on <size>: <table><tr><td><size> == 16</td><td><align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.</td></tr><tr><td><size> == 32</td><td><align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.</td></tr></table> : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see The Advanced SIMD addressing mode on page F2-2427 . | <size> == 8 | Encoded in the "index_align<0>" field as 0. | <size> == 16 | Encoded in the "index_align<1:0>" field as 0b00. | <size> == 32 | Encoded in the "index_align<2:0>" field as 0b000. | <size> == 16 | <align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01. | <size> == 32 | <align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011. |
| <size> == 8 | Encoded in the "index_align<0>" field as 0. | | | | | | | | | | |
| <size> == 16 | Encoded in the "index_align<1:0>" field as 0b00. | | | | | | | | | | |
| <size> == 32 | Encoded in the "index_align<2:0>" field as 0b000. | | | | | | | | | | |
| <size> == 16 | <align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01. | | | | | | | | | | |
| <size> == 32 | <align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011. | | | | | | | | | | |
| <Rm> | Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field. | | | | | | | | | | |

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d],index] = MemU[address,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

F6.1.85 VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

| | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|---|---|----|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 16 | 15 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 0 |

Offset variant

Applies when Rm == 1111.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Post-indexed variant

Applies when Rm == 1101.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Post-indexed variant

Applies when Rm != 11x1.

VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```
if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size); regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;
d = UInt(D:Vd); n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

```

CONSTRAINED UNPREDICTABLE behavior

If d+regs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD1 (single element to all lanes)* on page K1-5470.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 - 8 when size = 00
 - 16 when size = 01
 - 32 when size = 10
 The encoding size = 11 is reserved.
- <list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
 - { <Dd>[] } Encoded in the "T" field as 0.
 - { <Dd>[], <Dd+1>[] } Encoded in the "T" field as 1.

- The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>:
- | | |
|--------------|---|
| <size> == 16 | <align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1. |
| <size> == 32 | <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1. |
- : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    bits(64) replicated_element = Replicate(MemU[address,ebytes]);
    for r = 0 to regs-1
        D[d+r] = replicated_element;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

F6.1.86 VLD1 (multiple single elements)

Load multiple single 1-element structures to one, two, three, or four registers loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see *The Advanced SIMD addressing mode on page F2-2427*.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support on page G1-3881*.

Post-indexed variant

Applies when Rm != 11x1.

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' then SEE VLD2 (single 2-element structure to all lanes);
case size of
  when '00'
    ebytes = 1; index = UInt(index_align<3:1>); inc = 1;
    alignment = if index_align<0> == '0' then 1 else 2;
  when '01'
    ebytes = 2; index = UInt(index_align<3:2>);
    inc = if index_align<1> == '0' then 1 else 2;
    alignment = if index_align<0> == '0' then 1 else 4;
  when '10'
    if index_align<1> != '0' then UNDEFINED;
    ebytes = 4; index = UInt(index_align<3>);
    inc = if index_align<2> == '0' then 1 else 2;
    alignment = if index_align<0> == '0' then 1 else 8;
d = UInt(D:Vd); d2 = d + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d2 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD2 (single 2-element structure to one lane)* on page K1-5470.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
8 when size = 00
16 when size = 01
32 when size = 10
- <list> Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of:
{ <Dd>[<index>], <Dd+1>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.
{ <Dd>[<index>], <Dd+2>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
The encoding of "spacing" depends on <size>:
<size> == 16 "spacing" is encoded in the "index_align<1>" field.
<size> == 32 "spacing" is encoded in the "index_align<2>" field.
The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
<size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and the encoding depends on <size>:
<size> == 8 Encoded in the "index_align<0>" field as 0.
<size> == 16 Encoded in the "index_align<0>" field as 0.
<size> == 32 Encoded in the "index_align<1:0>" field as 0b00.
Whenever <align> is present, the permitted values and encoding depend on <size>:
<size> == 8 <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 16 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.
<size> == 32 <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

F6.1.88 VLD2 (single 2-element structure to all lanes)

Load single 2-element structure and replicate to all lanes of two registers loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD3 \(single 3-element structure to one lane\)](#) on page K1-5471.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
- | | |
|----|----------------|
| 8 | when size = 00 |
| 16 | when size = 01 |
| 32 | when size = 10 |
- <list> Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of:
- { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] }
 Single-spaced registers, encoded as "spacing" = 0.
- { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] }
 Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
- The encoding of "spacing" depends on <size>:
- | | |
|--------------|--|
| <size> == 8 | "spacing" is encoded in the "index_align<0>" field. |
| <size> == 16 | "spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0. |
| <size> == 32 | "spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00. |
- The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
- | | |
|--------------|--|
| <size> == 8 | <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. |
| <size> == 16 | <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. |
| <size> == 32 | <index> is 0 or 1, encoded in the "index_align<3>" field. |
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Alignment

Standard alignment rules apply, see [Alignment support on page B2-76](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    Elem[D[d], index] = MemU[address, ebytes];
    Elem[D[d2], index] = MemU[address+ebytes, ebytes];
    Elem[D[d3], index] = MemU[address+2*ebytes, ebytes];
    if wback then
        if register_index then
  
```

```
R[n] = R[n] + R[m];  
else  
R[n] = R[n] + 3*bytes;
```

F6.1.91 VLD3 (single 3-element structure to all lanes)

Load single 3-element structure and replicate to all lanes of three registers loads one 3-element structure from memory into all lanes of three registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

A1

Offset variant

Applies when Rm == 1111.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]

Post-indexed variant

Applies when Rm == 1101.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!

Post-indexed variant

Applies when Rm != 11x1.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```

if size == '11' || a == '1' then UNDEFINED;
ebytes = 1 << UInt(size);
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

Offset variant

Applies when Rm == 1111.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]

Post-indexed variant

Applies when Rm == 1101.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!

Post-indexed variant

Applies when Rm != 11x1.

VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```
if size == '11' || a == '1' then UNDEFINED;
ebytes = 1 << UInt(size);
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD3 (single 3-element structure to all lanes)* on page K1-5471.

Assembler symbols

- <c> For encoding A1: see *Standard assembler syntax fields* on page F2-2406. This encoding must be unconditional.
 For encoding T1: see *Standard assembler syntax fields* on page F2-2406.
- <q> See *Standard assembler syntax fields* on page F2-2406.
- <size> Is the data size, encoded in the "size" field. It can have the following values:

| | |
|----|----------------|
| 8 | when size = 00 |
| 16 | when size = 01 |
| 32 | when size = 10 |

 The encoding size = 11 is reserved.
- <list> Is a list containing the 64-bit names of three SIMD&FP registers. The list must be one of:

```
{ <Dd>[], <Dd+1>[], <Dd+2>[] }
```

 Single-spaced registers, encoded in the "T" field as 0.

{ <Dd>[], <Dd+2>[], <Dd+4>[] }

Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Alignment

Standard alignment rules apply, see [Alignment support on page B2-76](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n];
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```

F6.1.92 VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see [Element and structure load/store instructions on page F1-2388](#). Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

CONSTRAINED UNPREDICTABLE behavior

If d3 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD3 (multiple 3-element structures)* on page K1-5471.

Related encodings: See *Advanced SIMD element or structure Load/Store* on page F3-2479 for the T32 instruction set, or *Advanced SIMD element or structure Load/Store* on page F4-2553 for the A32 instruction set.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 10
 The encoding size = 11 is reserved.
- <list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:
 { <Dd>, <Dd+1>, <Dd+2> }
 Single-spaced registers, encoded in the "type" field as 0b0100.
 { <Dd>, <Dd+2>, <Dd+4> }
 Double-spaced registers, encoded in the "type" field as 0b0101.
 The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "align" field as 0b00. Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1

```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD4 (single 4-element structure to one lane)* on page K1-5471.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
- | | |
|----|----------------|
| 8 | when size = 00 |
| 16 | when size = 01 |
| 32 | when size = 10 |
- <list> Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of:
- { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] }
 Single-spaced registers, encoded as "spacing" = 0.
- { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }
 Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.
- The encoding of "spacing" depends on <size>:
- | | |
|--------------|---|
| <size> == 16 | "spacing" is encoded in the "index_align<1>" field. |
| <size> == 32 | "spacing" is encoded in the "index_align<2>" field. |
- The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:
- | | |
|--------------|--|
| <size> == 8 | <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. |
| <size> == 16 | <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. |
| <size> == 32 | <index> is 0 or 1, encoded in the "index_align<3>" field. |
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and the encoding depends on <size>:
- | | |
|--------------|--|
| <size> == 8 | Encoded in the "index_align<0>" field as 0. |
| <size> == 16 | Encoded in the "index_align<0>" field as 0. |
| <size> == 32 | Encoded in the "index_align<1:0>" field as 0b00. |
- Whenever <align> is present, the permitted values and encoding depend on <size>:
- | | |
|--------------|--|
| <size> == 8 | <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1. |
| <size> == 16 | <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1. |
| <size> == 32 | <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10. |
- : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2], index] = MemU[address+ebytes,ebytes];
    Elem[D[d3], index] = MemU[address+2*ebytes,ebytes];
    Elem[D[d4], index] = MemU[address+3*ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

F6.1.94 VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode see *The Advanced SIMD addressing mode* on page F2-2427.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support* on page G1-3881.

Offset variant

Applies when Rm == 1111.

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Post-indexed variant

Applies when Rm == 1101.

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Post-indexed variant

Applies when Rm != 11x1.

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```

if size == '11' && a == '0' then UNDEFINED;
if size == '11' then
    ebytes = 4; alignment = 16;
else
    ebytes = 1 << UInt(size);
    if size == '10' then
        alignment = if a == '0' then 1 else 8;
    else
        alignment = if a == '0' then 1 else 4*ebytes;
inc = if T == '0' then 1 else 2;
d = UInt(D:Vd); d2 = d + inc; d3 = d2 + inc; d4 = d3 + inc; n = UInt(Rn); m = UInt(Rm);
wback = (m != 15); register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
  
```

CONSTRAINED UNPREDICTABLE behavior

If d4 > 31, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly *VLD4 (single 4-element structure to all lanes)* on page K1-5472.

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
- For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).

- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <size> Is the data size, encoded in the "size" field. It can have the following values:
 8 when size = 00
 16 when size = 01
 32 when size = 1x
- <list> Is a list containing the 64-bit names of four SIMD&FP registers. The list must be one of:
 { <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] }
 Single-spaced registers, encoded in the "T" field as 0.
 { <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] }
 Double-spaced registers, encoded in the "T" field as 1.
 The register <Dd> is encoded in the "D:Vd" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- <align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access on page E2-2323](#), and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>:
 <size> == 8 <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
 <size> == 16 <align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
 <size> == 32 <align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.
 : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [The Advanced SIMD addressing mode on page F2-2427](#).
- <Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [The Advanced SIMD addressing mode on page F2-2427](#).

Operation for all encodings

```

if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    address = R[n]; iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
  
```

F6.1.95 VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see [Element and structure load/store instructions on page F1-2388](#). Every element of each register is loaded. For details of the addressing mode see [The Advanced SIMD addressing mode on page F2-2427](#).

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        Elem[D[d4],e] = MemU[address+3*ebytes,ebytes];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;
  
```

F6.1.96 VLDM, VLDMDB, VLDMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

This instruction is used by the alias VPOP. See [Alias conditions on page F6-3461](#) for details of when each alias is preferred.

A1

Decrement Before variant

Applies when P == 1 && U == 0 && W == 1.

VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>

Increment After variant

Applies when P == 0 && U == 1.

VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
 VLDMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>

Decode for all variants of this encoding

```

if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE VLDR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE; add = (U == '1'); wback = (W == '1');
d = UInt(D:Vd); n = UInt(Rn); imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2; // If UInt(imm8) is odd, see "FLDMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
    
```

CONSTRAINED UNPREDICTABLE behavior

If regs == 0, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If regs > 16 || (d+regs) > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

Decrement Before variant

Applies when $P == 1 \ \&\& \ U == 0 \ \&\& \ W == 1$.

VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <sreglist>

Increment After variant

Applies when $P == 0 \ \&\& \ U == 1$.

VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <sreglist>

if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLDM on page K1-5472](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move on page F3-2448](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move on page F4-2532](#) for the A32 instruction set.

Alias conditions

| Alias | is preferred when |
|-------|---|
| VPOP | <code>P == '0' && U == '1' && W == '1' && Rn == '1101'</code> |

Assembler symbols

| | |
|------------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| <size> | An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. |
| ! | Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0. |
| <reglist> | Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register. |
| <dreglist> | Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4]; address = address+4;
        else
            word1 = MemA[address,4]; word2 = MemA[address+4,4]; address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

F6.1.97 VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

Assembler symbols

| | |
|-------|---|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| .64 | Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| .32 | Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Sd> | Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field. |
| <Rn> | Is the general-purpose base register, encoded in the "Rn" field. |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <imm> | Is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4. |

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4]; word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian() then word1:word2 else word2:word1;
```

F6.1.98 VLDR (literal)

Load SIMD&FP register (literal) loads a single register from the Advanced SIMD and floating-point register file, using an address from the PC value and an immediate offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

Single-precision scalar variant

Applies when size == 10.

VLDR{<c>}{<q>}{.32} <Sd>, <label>
 VLDR{<c>}{<q>}{.32} <Sd>, [PC, #{+/-}<imm>]

Double-precision scalar variant

Applies when size == 11.

VLDR{<c>}{<q>}{.64} <Dd>, <label>
 VLDR{<c>}{<q>}{.64} <Dd>, [PC, #{+/-}<imm>]

Decode for all variants of this encoding

```
if size IN { '00', '01' } then UNDEFINED;
esize = 8 << UInt(size); add = (U == '1');
imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
```

T1

Single-precision scalar variant

Applies when size == 10.

VLDR{<c>}{<q>}{.32} <Sd>, <label>
 VLDR{<c>}{<q>}{.32} <Sd>, [PC, #{+/-}<imm>]

Double-precision scalar variant

Applies when size == 11.

VLDR{<c>}{<q>}{.64} <Dd>, <label>
 VLDR{<c>}{<q>}{.64} <Dd>, [PC, #{+/-}<imm>]

Decode for all variants of this encoding

```
if size IN { '00', '01' } then UNDEFINED;
esize = 8 << UInt(size); add = (U == '1');
imm32 = if esize == 16 then ZeroExtend(imm8:'0', 32) else ZeroExtend(imm8:'00', 32);
d = UInt(D:Vd); n = UInt(Rn);
```

Assembler symbols

| | |
|---------|--|
| <c> | See Standard assembler syntax fields on page F2-2406 . |
| <q> | See Standard assembler syntax fields on page F2-2406 . |
| .64 | Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| .32 | Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored. |
| <Sd> | Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field. |
| <label> | The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the <code>Align(PC, 4)</code> value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, <code>imm32</code> is equal to the offset and <code>add == TRUE</code> . If the offset is negative, <code>imm32</code> is equal to minus the offset and <code>add == FALSE</code> . |
| +/- | Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in the "U" field. It can have the following values: - when U = 0 + when U = 1 |
| <imm> | Is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <code><imm>/4</code> . |

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax on page F1-2369](#).

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4]; word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian() then word1:word2 else word2:word1;
```

F6.1.99 VMAX (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are 32-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMAX{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMAX{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMAX{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

Assembler symbols

| | |
|------|---|
| <c> | For encoding A1: see <i>Standard assembler syntax fields</i> on page F2-2406. This encoding must be unconditional. For encoding T1: see <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32 when sz = 0 |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |

Floating-point maximum and minimum

- $\max(+0.0, -0.0) = +0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

Operation for all encodings

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
```

F6.1.100 VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
 - S8 when U = 0, size = 00
 - S16 when U = 0, size = 01
 - S32 when U = 0, size = 10
 - U8 when U = 1, size = 00
 - U16 when U = 1, size = 01
 - U32 when U = 1, size = 10
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Int(Elem[D[n+r],e,esize], unsigned);
      op2 = Int(Elem[D[m+r],e,esize], unsigned);
      result = if maximum then Max(op1,op2) else Min(op1,op2);
      Elem[D[d+r],e,esize] = result<esize-1:0>;
  
```

F6.1.101 VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMAXNM{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMAXNM{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');

if InITBlock() then UNPREDICTABLE;
    
```

A2

Single-precision scalar variant

Applies when size == 10.

VMAXNM{<q>}.F32 <Sd>, <Sn>, <Sm> // Cannot be conditional

Double-precision scalar variant

Applies when size == 11.

VMAXNM{<q>}.F64 <Dd>, <Dn>, <Dm> // Cannot be conditional

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
advsimd = FALSE;
maximum = (op == '0');
case size of
    
```

```

    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
    if InITBlock() then UNPREDICTABLE;
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMAXNM{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMAXNM{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

    if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
    if sz == '1' then UNDEFINED;
    maximum = (op == '0');
    advsimd = TRUE;
    esize = 32; elements = 2;
    d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    if InITBlock() then UNPREDICTABLE;
    
```

T2

Single-precision scalar variant

Applies when size == 10.

VMAXNM{<q>}.F32 <Sd>, <Sn>, <Sm> // Not permitted in IT block

Double-precision scalar variant

Applies when size == 11.

VMAXNM{<q>}.F64 <Dd>, <Dn>, <Dm> // Not permitted in IT block

Decode for all variants of this encoding

```

    if size != '1x' then UNDEFINED;
    advsimd = FALSE;
    maximum = (op == '0');
    case size of
        when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);

            if maximum then
                D[d] = FPMaxNum(D[n], D[m], FPSCR);
            else
                D[d] = FPMinNum(D[n], D[m], FPSCR);
  
```

F6.1.102 VMIN (floating-point)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are 32-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

Assembler symbols

| | |
|------|---|
| <c> | For encoding A1: see <i>Standard assembler syntax fields</i> on page F2-2406. This encoding must be unconditional. For encoding T1: see <i>Standard assembler syntax fields</i> on page F2-2406. |
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32 when sz = 0 |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |

Floating-point minimum

- $\min(+0.0, -0.0) = -0.0$
- If any input is a NaN, the corresponding result element is the default NaN.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Elem[D[n+r],e,esize]; op2 = Elem[D[m+r],e,esize];
      if maximum then
        Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
      else
        Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
  
```

F6.1.103 VMIN (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
maximum = (op == '0'); unsigned = (U == '1');
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMIN{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMIN{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
maximum = (op == '0'); unsigned = (U == '1');
esize = 8 << UInt(size); elements = 64 DIV esize;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
  
```

Assembler symbols

- <c> For encoding A1: see [Standard assembler syntax fields on page F2-2406](#). This encoding must be unconditional.
 For encoding T1: see [Standard assembler syntax fields on page F2-2406](#).
- <q> See [Standard assembler syntax fields on page F2-2406](#).
- <dt> Is the data type for the elements of the operands, encoded in the "U:size" field. It can have the following values:
- | | |
|-----|-----------------------|
| S8 | when U = 0, size = 00 |
| S16 | when U = 0, size = 01 |
| S32 | when U = 0, size = 10 |
| U8 | when U = 1, size = 00 |
| U16 | when U = 1, size = 01 |
| U32 | when U = 1, size = 10 |
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation for all encodings

```

if ConditionPassed() then
  EncodingSpecificOperations(); CheckAdvSIMDEnabled();
  for r = 0 to regs-1
    for e = 0 to elements-1
      op1 = Int(Elem[D[n+r],e,esize], unsigned);
      op2 = Int(Elem[D[m+r],e,esize], unsigned);
      result = if maximum then Max(op1,op2) else Min(op1,op2);
      Elem[D[d+r],e,esize] = result<esize-1:0>;
  
```

F6.1.104 VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMIN.

This instruction is not conditional.

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMINNM{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMINNM{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
advsimd = TRUE;
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
    
```

A2

Single-precision scalar variant

Applies when size == 10.

VMINNM{<q>}.F32 <Sd>, <Sn>, <Sm> // Cannot be conditional

Double-precision scalar variant

Applies when size == 11.

VMINNM{<q>}.F64 <Dd>, <Dn>, <Dm> // Cannot be conditional

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
advsimd = FALSE;
maximum = (op == '0');
case size of
    
```

```

when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
  
```

T1

64-bit SIMD vector variant

Applies when Q == 0.

VMINNM{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMINNM{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
maximum = (op == '0');
advsimd = TRUE;
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
  
```

T2

Single-precision scalar variant

Applies when size == 10.

VMINNM{<q>}.F32 <Sd>, <Sn>, <Sm> // Not permitted in IT block

Double-precision scalar variant

Applies when size == 11.

VMINNM{<q>}.F64 <Dd>, <Dn>, <Dm> // Not permitted in IT block

Decode for all variants of this encoding

```

if size != '1x' then UNDEFINED;
advsimd = FALSE;
maximum = (op == '0');
case size of
  when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
  when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
if InITBlock() then UNPREDICTABLE;
  
```

Notes for all encodings

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Appendix K1 Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler symbols

| | |
|------|--|
| <q> | See <i>Standard assembler syntax fields</i> on page F2-2406. |
| <dt> | Is the data type for the elements of the vectors, encoded in the "sz" field. It can have the following values: F32 when sz = 0 |
| <Qd> | Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2. |
| <Qn> | Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2. |
| <Qm> | Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2. |
| <Dd> | Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. |
| <Dn> | Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field. |
| <Dm> | Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field. |
| <Sd> | Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field. |
| <Sn> | Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field. |
| <Sm> | Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field. |

Operation for all encodings

```

EncodingSpecificOperations(); CheckAdvSIMDorVFPEnabled(TRUE, advsimd);
if advsimd then // Advanced SIMD instruction
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r], e, esize]; op2 = Elem[D[m+r], e, esize];
            if maximum then
                Elem[D[d+r], e, esize] = FPMaXNum(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r], e, esize] = FPMiNNum(op1, op2, StandardFPSCRValue());
else // VFP instruction
    case esize of
        when 32
            if maximum then
                S[d] = FPMaXNum(S[n], S[m], FPSCR);
            else
                S[d] = FPMiNNum(S[n], S[m], FPSCR);
        when 64
            if maximum then
                D[d] = FPMaXNum(D[n], D[m], FPSCR);
            else
                D[d] = FPMiNNum(D[n], D[m], FPSCR);
  
```

F6.1.105 VMLA (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support on page G1-3881](#).

A1

64-bit SIMD vector variant

Applies when Q == 0.

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm>

128-bit SIMD vector variant

Applies when Q == 1.

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Qm>

Decode for all variants of this encoding

```

if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' then UNDEFINED;
advsimd = TRUE; add = (op == '0');
esize = 32; elements = 2;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = if Q == '0' then 1 else 2;
    
```

A2

Single-precision scalar variant

Applies when size == 10.

VMLA{<c>}{<q>}.F32 <Sd>, <Sn>, <Sm>
